This book is the first volume of a series of "Wissenschaftliche Forschungsberichte" whose object is to indicate the more important contributions to particular fields of science since 1914. The publication of this series is of interest as indicating the steps which are being taken in Germany to "rehabilitate" research by familiarizing the investigator with recently published data, which may not be readily available to him. The present volume treats developments in analytical chemistry from this standpoint. In the introduction it is suggested that advances in analytical chemistry from the beginning of this century to the outbreak of the World War have been especially noteworthy in three directions: (1) the utilization of special organic reagents, such as cupferron and dimethylglyoxime; (2) improvements in physical instruments and increase in their use; for example, the refractometer, colorimeter, and nephelometer; (3) the in-

creased use of physico-chemical principles, especially in the treatment of volumetric analysis.

The subjects treated are the detection, estimation, and separation of the common elements and a few of the rare ones, together with many inorganic anions. The determination of gases in metals, and the elementary analysis of organic substances are also included.

As in any similar case, the selection of the "more important" contributions is a matter of opinion both in regard to omissions and inclusions, and the judgment of the author will not always coincide with that of the reader. Nevertheless, the fact that there are more than 500 footnote references (including duplicates) and that these contain a liberal admixture of other than German references (about 60% are to German periodicals) indicates that the author has attempted a thorough treatment of his subject.

In a book of 86 pages the discussion of each item is necessarily too brief to include many details of operation. The book should, however, fulfil a useful function for the investigator by giving him suggestions from and references to recent advances in analytical chemistry which he could hardly obtain otherwise except by considerable study of the literature.

GRAHAM EDGAR.

**A French-English Dictionary for Chemists.** By AUSTIN M. PATTERSON, PH. D. John Wiley and Sons, Inc., New York; Chapman and Hall, Limited, London, 1921. xvii + 384 pp. 18 × 12.5 cm. Price \$3.00.

It is a pleasure to welcome a companion volume to Dr. Patterson's useful German dictionary, and the present work embodies the successful features of the other. The book is handy to use, the pages are easy to read at a glance, and the restriction of the vocabulary saves much time and space. In general the selection of words and idioms is excellent, and the translations are accurate.

As Dr. Patterson in his preface invites suggestions, the following points are mentioned.

A current French industrial journal yielded the following words not given in the dictionary: *amodier*, *amodiation*, *acier à coupe rapide*, *déprimomètre*, *remous*. *Calvine* should certainly find a place among medical terms. *Rationnel* means something like "scientific" at least as often as "rational." *Admettre* is insufficiently accounted for by "admit, accept (as true), receive, allow, concede." It often means "postulate," or "suppose." Cf. "Ce chimiste (Avogadro) admit que des volumes égaux . . . contiennent des nombres égaux de molécules." Even though "strong, thick, hard, difficult, severe, skillful, clever" are given for *fort* (a), some such additional adjective as "large" or "great" seems to be necessary in "*une forte proportion*." *Faible* is somewhat better, as we find "slight" as well as "weak" and "feeble," but how about "*la densité du gaz sera plus faible?*" The meaning

"early" for *précoce*, need not have been restricted to "fruit;" it is often applied, for instance, to frost and baldness.

The book is a good one, and will probably be further improved. Chemists who read French need it.

NORRIS F. HALL.

**Die Biogenen Amine und ihre Bedeutung für die Physiologie und Pathologie des Pflanzlichen und Tierischen Stoffwechsels.** (The Biogenic Amines and their Significance for the Physiology and Pathology of Plant and Animal Metabolism.) By M. GUGGENHEIM. Julius Springer, Berlin, 1920. viii + 376 pp. 14.5 X 21.5 cm.

A compilation of the literature on biogenic amines down to the early months of 1919 both from the viewpoint of the chemist and the pharmacologist. The amines are classified as follows: alkyl amines, alkamines, neurine group, diamines, guanidine compounds, amidazol compounds, betaines and  $\alpha$ -amino acids, phenyl-alkyl and phenyl-alkanol amines, indol-ethylamine.

Seventy pages of references are included.

The author has worked extensively in this field, which as stated in his preface, had been well covered in 1914 by Barger's "The Simpler Natural Bases," Longmans, Green and Company, London.

GERMANIUM.<sup>1</sup> I. EXTRACTION FROM GERMANIUM-BEARING  
ZINC OXIDE. NON-OCCURRENCE IN SAMARSKITE.

BY L. M. DENNIS AND JACOB PAPISH.

Received June 25, 1921.

Material.

Argyrodite and canfieldite, which at present are the only minerals known to contain germanium as a definite constituent, are too rare to be regarded as sources of supply of the element. Bardet<sup>2</sup> examined various mineral waters spectroscopically and found that germanium was present in many of them. He succeeded in extracting 60 mg. of germanium dioxide from about 100 kilograms of residues, chiefly calcium carbonate, obtained in the manufacture of Vichy salts from the natural waters. This amount of germanium dioxide represented 250,000 liters of original Vichy water and corresponded to 0.00024 mg. of germanium dioxide per

<sup>1</sup> This article is based upon a part of the thesis presented to the Faculty of the Graduate School of Cornell University by Jacob Papish in partial fulfilment of the requirements for the degree of Doctor of Philosophy.

Some details of manipulation and additional comments on the history of germanium have been omitted from this article. They will appear in an unabridged version to be published later in the *Zeitschrift für anorganische und allgemeine Chemie*.

liter of water, a quantity too small to render these waters a practical source of supply of germanium. The extraction of germanium directly from blends, as has been carried out by Urbain, is a very expensive and tedious operation. The most promising source of the element at the present time is the concentrate from certain residues obtained in the smelting of American zinc ores. Buchanan<sup>3</sup> reported that one such residue contained as much as 0.25 % of germanium dioxide. A large supply of this most valuable material was presented to the Department of Chemistry of Cornell University by the New Jersey Zinc Company and the present investigation, as well as others that will follow from this laboratory, would not have been possible except for the generous coöperation of this company. Concerning the origin of this material, Mr. W. M. Kelsey,<sup>4</sup> Superintendent of the Palmerton plant of the New Jersey Zinc Company, states that it was obtained "by a fire concentration of certain residues produced in the ordinary process of smelting for zinc. The original ore was a mixture of high grade sulfides from the Wisconsin and Missouri fields, roughly in the ratio of two parts of Wisconsin ore to one part of Missouri ore."

### Extraction of Germanium.

None of the various methods that were employed by Winkler for the extraction of germanium from argyrodite is adapted to the separation of the element from the germanium-bearing zinc oxide, because the association of elements in this latter material is quite different from that in argyrodite. Zinc oxide is, of course, present in preponderating amount and the concentrate further contains considerable quantities of lead, arsenic, and cadmium, and also traces of other elements, among them being indium, tin, and antimony.

Preliminary trials were made of a variety of possible methods of separation, but as none of these was found to be satisfactory, descriptions of them will not be given here. The procedure that was finally adopted is based upon the volatility of germanium tetrachloride, and is an elaboration of the method described by Buchanan.<sup>3</sup> The essential features of this process consist in treating the crude zinc oxide with hydrochloric acid and then distilling the germanium tetrachloride in a current of chlorine. The chlorine maintains the arsenic in pentavalent form and thus prevents the distillation of arsenic trichloride with the germanium tetrachloride.

In the first trials of this method, portions of the crude zinc oxide of from 250 to 1000 g. each were treated with hydrochloric acid, chlorine gas was passed through the apparatus, and the mixture was heated to effect the distillation of the germanium tetrachloride. This gave a product substantially free from arsenic, but the necessity for long passage of large

<sup>4</sup> Letter to L. M. Dennis, September 3, 1919.

amounts of chlorine through the apparatus rendered the procedure unsuited to the extraction of germanium on a large scale from several hundred pounds of the crude material. Browning and Scott<sup>5</sup> substituted potassium permanganate, manganese dioxide, potassium chlorate, or potassium dichromate for chlorine. They used the method for the detection of germanium in very small samples that contained less than a gram of arsenic trioxide or pentoxide and not more than 5 mg. of germanium. But even so they found that when from 0.3 to 0.5 g. of  $\text{As}_2\text{O}_3$  was used, some arsenic appeared in the distillate. It is apparently essential that if the formation of arsenic trichloride and its consequent appearance in the distillate are to be avoided, the concentration of chlorine must be high throughout the whole distillation.

Fresenius<sup>6</sup> states that when a mixture of sodium arsenate and conc. hydrochloric acid is distilled, small amounts of arsenic are volatilized. Mayrhofer<sup>7</sup> in attempting to remove arsenical impurities from hydrochloric acid noticed that even when the acid was first treated with chlorine or when some pyrolusite was added to the acid and it was then distilled, small amounts of arsenic were always found in the distillate. Hehner<sup>8</sup> distilled arsenic acid with strong hydrochloric acid and obtained comparatively large quantities of arsenic in the several fractions of the distillate. He states that "a similar result was obtained when potassium permanganate had been added before the beginning of the distillation, or, in other words, when the distillation was begun in the presence of chlorine."

In an investigation of the reaction between hydrogen sulfide and arsenic pentoxide in the presence of hydrochloric acid, Usher and Travers<sup>9</sup> studied the reaction between arsenic pentoxide and hydrogen chloride in sealed tubes. They concluded that the reaction is that expressed by the equation  $\text{As}_2\text{O}_5 + 10\text{HCl} \rightleftharpoons 2\text{AsCl}_3 + 2\text{Cl}_2 + 5\text{H}_2\text{O}$ , the equilibrium shifting rapidly to the right with increasing concentration of hydrogen chloride.

These observations upon the reduction of arsenic pentoxide by conc. hydrochloric acid and volatilization of arsenic trichloride when such a mixture is distilled, have been sustained by the experimental evidence accumulated in this laboratory during the progress of the investigation here described. When potassium permanganate was added to the crude zinc oxide and this was then distilled with an excess of conc. hydrochloric acid, arsenic trichloride passed into the distillate. To maintain the concentration of chlorine, the procedure was modified by slowly running into the flask a solution of the potassium permanganate during the distillation with hydrochloric acid. It was found that the dilution of the acid soon rose to such an amount that the germanium tetrachloride instead of distilling off was hydrolyzed in the flask. To ascertain whether a mixture of sodium arsenate and sodium germanate, when distilled with an excess of conc. hydrochloric acid, would yield arsenic trichloride in the distillate, a mixture of the oxides of arsenic and germanium was fused with a slight excess of sodium peroxide, the fused mass was dissolved in water and the solution was heated to boiling. It was then cooled, and excess of hydrochloric acid was added and the liquid was distilled. The distillation gave a yellow precipitate with hydrogen sulfide which indi-

cated the presence of arsenic. In another experiment lead dioxide was used in place of sodium peroxide. Arsenic here also passed into the distillate. These experiments, as well as the observations of previous investigators, indicate that arsenic acid is reduced to arsenic trichloride during distillation with hydrochloric acid unless a high concentration of chlorine throughout the distillation is maintained.

To ascertain whether arsenic trioxide when dissolved in sodium hydroxide, saturated with chlorine, and then acidified with hydrochloric acid, would yield any arsenic trichloride when distilled in a current of chlorine, 5 g. of arsenic trioxide was dissolved in 20 cc. of a 30% solution of potassium hydroxide, this solution was saturated with chlorine, and then, without interrupting the current of chlorine, 190 cc. of pure conc. hydrochloric acid was added and the liquid was distilled. A Reitmaier-Stutzer bulb was used to prevent so far as possible the mechanical passage of some of the liquid into the distillate. Two fractions of 40 cc. each were obtained. Each of these was saturated with hydrogen sulfide. After 12 hours there separated a few small yellow particles that resembled sulfur. These were tested for arsenic by heating them with nitric acid, adding ferrous sulfate to reduce the nitric acid, then adding dil. sulfuric acid and warming the mixture to remove oxides of nitrogen, and finally subjecting the material to the "modified Gutzzeit test."<sup>10</sup> The reaction was allowed to proceed for 10 minutes but no discoloration of the crystal of silver nitrate was discernible.

Müller,<sup>11</sup> in a recent article upon the atomic weight of germanium, states "The chlorine—hydrochloric acid distillation process, though adequate for the removal of silica and tin, can hardly be accepted as a means of eliminating the last traces of arsenic from germanium compounds. Four redistillations of the chloride from hydrochloric acid solution in a stream of chlorine failed to remove the last of the arsenic." Careful perusal of his article fails to reveal experimental support for this statement. In fact, in his description of the purification of germanium, he remarks that the precipitation of redistilled germanium tetrachloride by hydrogen sulfide yielded a "snow-white germanium sulfide." The point is of importance, and the possible presence of arsenic in the distilled germanium tetrachloride will be followed carefully during further work in this laboratory.

To avoid the necessity for the use of the very large amounts of chlorine that would be called for if the germaniferous zinc oxide were directly distilled with hydrochloric acid in a current of chlorine for the separation of germanium, it was decided to distil germanium tetrachloride and arsenic trichloride together from the crude zinc oxide and thus to effect, as a first step, the separation of the germanium from the large amount of the zinc oxide that is present in the original material.

### Apparatus.

The unit still consists of a round-bottom 5-liter Pyrex flask supported on an asbestos "collar"<sup>12</sup> 10 cm. high, the collar resting on an iron plate and this on a strong tripod. A 2-hole rubber stopper in the neck of the

<sup>10</sup> Dennis and Whittelsey, "Qualitative Analysis," Ginn and Co., Revised Ed., p. 31.

<sup>11</sup> Müller, *THIS JOURNAL*, 43, 1085 (1921).

<sup>12</sup> This device for heating glass or porcelain vessels that contain a mixture of liquid and solid materials has been in use in the Cornell Laboratory for several years. A

flask carries a bent glass tube for connection with a Liebig condenser, and through the other opening of the stopper is inserted a short glass tube through which the desired amount of conc. hydrochloric acid may be blown into the flask by air pressure from a large graduated bottle. After the acid has been driven into the flask in the actual operation, the glass tube is replaced by a solid glass plug. A bent glass tube is attached to the farther end of the condenser by means of a short piece of rubber tubing. This glass tube is about 10 mm. in diameter and reaches nearly to the bottom of a 4-liter bottle which serves as a receiver. The iron plate upon which the collar rests is heated with a large Meker burner, and to avoid loss of heat, the tripod is surrounded by sheets of asbestos board. The duration of each distillation is further shortened by covering the upper part of the flask with an asbestos jacket. This jacket is made by first covering that part of the flask which projects above the collar with a layer of moist filter paper. Asbestos felt which had been soaked in water is then laid upon the paper in over-lapping pieces and smoothed down to an even, continuous layer. Wet asbestos cement is then laid over the whole exterior of the jacket. The opening in the top of the jacket is made sufficiently large to permit of the removal of the cap from the flask. The cap is allowed to dry on the flask and is then removed and its lower edge and the upper rim are dipped in a solution of sodium silicate to stiffen them. The receiver stands in an earthenware jar.

### Distillation.

One kilogram of the crude zinc oxide is introduced into the flask, water is placed in the receiver to such a depth as just to cover the end of the glass tube, and the earthenware jar in which the bottle stands is filled with cracked ice. Twenty-five hundred cc. of commercial conc. hydrochloric acid (1.18 sp. gr.) is next driven into the flask through the glass tube in the stopper, and the tube is then replaced by a solid glass plug. The heating of the flask is begun and continued until 2000 cc. of the distillate has collected, this amount having been shown spectroscopically to suffice for the recovery of all the germanium.

"collar" is made from asbestos board 3 to 6 mm. thick, a strip of the board of the desired width being first thoroughly wet with water, then bent into a circle and fastened at the over-lapping ends with iron or copper wire, and finally dried. The "collars" may of course be made of any desired diameter. The collar is placed upon an iron plate about 3 mm. thick and this plate rests in turn upon an iron tripod. If the collar is dipped in a dilute solution of sodium silicate, it becomes stiff when dry, and although somewhat brittle, its life is prolonged by this treatment. A glass flask or porcelain evaporator placed on one of these collars does not come into direct contact with the gas flames under the iron plate, and local heating that would result from the direct application of the flame to the container, which often causes the fracture of the vessel, is thus avoided. The collar is especially useful in the long digestion of a powdered mineral with acids.

### The Precipitation of Germanium and Arsenic by Hydrogen Sulfide.

The acid distillate may now be treated with hydrogen sulfide in such manner as to precipitate all of the arsenic and germanium that are present, or the conditions may be so regulated as to cause the precipitation of arsenic trisulfide alone or mixed with only a very small amount of germanium sulfide. This last procedure was used by Winkler<sup>13</sup> and is now being studied in this laboratory. The method that we have employed up to the present time involves the simultaneous precipitation of the sulfides of germanium and arsenic.

Successive distillates are poured into a 15-liter glass bottle until about 10 liters of the solution has been collected. Since the precipitation of germanium disulfide is most complete when the acid concentration is about 6 *N*, conc. sulfuric acid is slowly added to the contents of the bottle until the acidity is brought to about this point. The acid is run in from a separatory funnel that passes through one opening of a 2-hole rubber stopper inserted in the neck of the bottle. Loss of germanium tetrachloride that might be volatilized during the addition of the sulfuric acid is avoided by placing in the other opening of the stopper a short, bent delivery tube that dips into a liter of 6 *N* sulfuric acid that has been saturated with hydrogen sulfide. Washed hydrogen sulfide is now passed through this solution. Yellow sulfide of arsenic is first precipitated. White germanium disulfide next appears, and if the liquid is not agitated, this white sulfide separates as a distinct layer on the top of the yellow sulfide of arsenic. When precipitation is complete, the large bottle is stoppered and is allowed to stand for 24 hours. The contents of the bottle is then brought upon a filter and the sulfides are washed with the aid of suction with 3 *N* sulfuric acid that has been saturated with hydrogen sulfide.

The filtrate from the sulfides of germanium and arsenic is placed in a large bottle or in a tall, covered, glass cylinder and allowed to stand for 48 hours. At the end of this time a slight precipitate of the sulfides separates. The supernatant liquid is then siphoned off and the bottle or cylinder is filled with the filtrate from the next precipitation which is again allowed to stand for 48 hours. When a fairly large amount of the sulfides has accumulated in the vessel, it is brought upon a filter and washed as before. The amount of germanium that is recovered by this treatment averages about 2 mg. for every liter of filtrate.

From this point forward two different procedures have been followed. In the first of these the moist sulfides are dissolved in a 50% solution of sodium hydroxide with the aid of heat. Successive portions of the sulfides are added to this solution until a small amount is left undissolved.

<sup>13</sup> Winkler, *J. prakt. Chem.*, **142**, 194 (1886).

This is then taken into solution by the addition of a little more of the concentrated solution of sodium hydroxide and then about 8 g. of solid sodium hydroxide is added to render the solution strongly alkaline which facilitates the later oxidation of the arsenic. This solution is then placed in a Pyrex flask which is provided with a rubber stopper that carries a delivery tube, a separatory funnel, and a glass tube that reaches nearly to the bottom of the flask. This last tube has a wider tube fused to its lower end to avoid stoppage. The flask is placed on an asbestos collar and is connected with a condenser and a receiver in the manner above described. Washed chlorine is then passed through the liquid in the flask to convert the arsenic to the pentavalent form. When the contents of the flask has been saturated with chlorine and the apparatus is filled with the gas, the speed of the flow of chlorine is lessened and conc. hydrochloric acid is run into the flask through the separatory funnel until the acid is in large excess. The flask is then heated and the germanium tetrachloride is distilled in a slow current of chlorine, the distillation being continued until half of the liquid in the flask has passed over.

The larger part of the germanium tetrachloride passes over between  $90^{\circ}$  and  $100^{\circ}$ . Instead of collecting the germanium tetrachloride as such from this distillation, some water is placed in the receiver to hydrolyze the compound. The resulting hydrated germanium dioxide is pure white in color. If any of the oily tetrachloride is seen to collect under the layer of liquid on the bottom of the receiver during the distillation, it is an indication that the concentration of hydrochloric acid in the receiver is so high as to repress the hydrolysis of the germanium tetrachloride. In such case more water is poured into the receiver. When half of the liquid in the flask has passed over, the receiver is removed and a fresh receiver containing some water is put in its place. A volume of conc. hydrochloric acid equal to the volume of the liquid that has distilled over is now run into the flask through the separatory funnel and the distillation is continued. When half of the liquid now in the flask has distilled over, most of the germanium tetrachloride has usually passed into the distillate, but it was found that complete separation of that element as the tetrachloride is effected only by many repetitions of the distillation.

The hydrated germanium dioxide is now collected on a small disk of filter paper supported by a Witt plate in a large funnel and is washed first with dil. sulfuric acid and then with small portions of cold water. It is transferred to an evaporating dish and is dried in an air bath at a temperature of  $110^{\circ}$ . Photographs of the arc spectra of various portions of this material showed that the germanium dioxide contained traces of sodium, calcium, and iron. Fractional precipitation of a solution of a sample of the dioxide by hydrogen sulfide failed to disclose the presence of arsenic.

Germanium in the filtrate and washings from the hydrolyzed germanium dioxide is recovered by precipitation with hydrogen sulfide.

To free the germanium dioxide from the traces of impurities noted above, it is dissolved in a slight excess of sodium hydroxide with the aid of heat, the solution is treated with chlorine in the manner above described, hydrochloric acid is added, and the germanium tetrachloride is again distilled in a current of chlorine and is hydrolyzed as before.

The above method for the separation of germanium and arsenic gives quite satisfactory results in respect to the completeness of the recovery of the germanium, but it is open to the following objections.

The precipitate of the mixed sulfides contains a preponderating amount of arsenious sulfide. This necessitates the use of large quantities of sodium hydroxide, chlorine, and hydrochloric acid, and greatly lengthens the time of treatment with chlorine. Again, the addition of hydrochloric acid to the chlorinated solution of the mixed sulfides in sodium hydroxide reprecipitates a part of the sulfides, and the conversion of the germanium in this precipitate into the volatile germanium tetrachloride by the action of hydrochloric acid and chlorine proceeds very slowly. Furthermore, a large amount of arsenic in the precipitate causes the appearance of some of that element in the distillate even though the current of chlorine through the apparatus is not interrupted during the distillation. This fact necessitates a second precipitation of the sulfides of germanium and arsenic and a redistillation in chlorine in order to free the germanium completely from arsenic.

It is evident that these difficulties would largely be obviated if the greater part of the arsenic could be separated from the germanium before distillation in chlorine. Preliminary experiments indicated that this separation could be accomplished by roasting the dried sulfides in air and this led to the development of the second procedure for the treatment of the mixed sulfides which is as follows.

If the mixed sulfides of germanium and arsenic are to be roasted, it is, of course, essential that the sulfide precipitate be washed free from chlorides before the roasting to avoid loss of germanium through volatilization of germanium tetrachloride. To this end the washing of the sulfides with 3 *N* sulfuric acid is continued until the chlorides are completely removed. The absence of chlorides in the wash-water is ascertained by adding cadmium nitrate to a portion of the liquid to precipitate the hydrogen sulfide, filtering off the precipitate, and then adding silver nitrate to the filtrate. The washed sulfides are transferred to a large evaporating dish and are dried in an air-bath at 110°.

The dried sulfides consist of from 78 to 90% of arsenious sulfide, the remainder being germanium disulfide and moisture, together with small quantities of sulfur and sulfuric acid. These dry, crude sulfides are placed in shallow iron dishes and are roasted in a muffle furnace at a tempera-

ture not to exceed 500°. This removes the greater part of the arsenic.

Up to 500° there is no loss of germanium, as shown by examining spectrographically the sublimate on a sheet of aluminum placed above the iron dish. At slightly above 600° there is a 30% and at 800–900° about a 90% loss of the germanium.

Each of three 100g. samples of the dried, crude sulfides yielded, on roasting, about 24 g. of the germaniferous residue. The actual decrease in the amount of arsenic was, however, greater than this difference of weight indicates, because of the formation of a considerable amount of iron oxide during the roasting. The extent of the removal of arsenic was approximately ascertained by determining the amount of arsenic in an unroasted sample and in that sample after roasting. Before roasting, the material contained 78.2%, and after roasting, 5.52% of arsenic calculated as the trisulfide,  $As_2S_3$ . These results indicate that somewhat over 90% of the arsenic is removed by this treatment.

The germanium in this residue is extracted by dissolving the finely pulverized material in a 50% solution of sodium hydroxide, chlorinating the solution, adding two parts by weight of conc. hydrochloric acid to every one part by weight of the roasted residue, and distilling. Usually, this completely removes the germanium and no more than faint traces of arsenic are found in the distillate. The resulting hydrated germanium dioxide is freed from the last traces of arsenic by dissolving it in sodium hydroxide, chlorinating the solution, and again distilling with hydrochloric acid in a current of chlorine.

This procedure of first roasting the mixed sulfides to remove the greater part of the arsenic and then distilling the germanium tetrachloride from the residue is superior to the first method of directly distilling the germanium tetrachloride from the mixed sulfides in that the consumption of materials is less, the time needed for the distillation is much shorter, and the separation from arsenic is more complete. It possesses, however, one drawback, the necessity of washing the mixed sulfides free from chlorides before roasting. If a small sample of the sulfides be washed with 3 N sulfuric acid that has been saturated with hydrogen sulfide, chlorides can be removed quite completely and the filtrate is free from detectable amounts of germanium, but it was found that when this method was used on a large scale, repeated washing with 3 N sulfuric acid yields eventually a milky filtrate which slowly deposits white germanium sulfide when its acidity is brought up to 6 N. 5 N sulfuric acid saturated with hydrogen sulfide was substituted for the 3 N acid. This gave a clear filtrate from which no appreciable amount of germanium sulfide separated on standing, but the removal of the chlorides was very slow. Attempts to wash the precipitated sulfides with 5 N sulfuric acid by decantation led to no satisfactory results.

Either of the above processes yields a very pure germanium dioxide. The first gives a somewhat higher yield and the second procedure is considerably shorter. The precipitation of arsenic trisulfide substantially free from germanium sulfide from weakly acid solutions is now being studied in the hope that a procedure superior to either of those above described may be developed.

### The Determination of Germanium.

To gage the efficiency of the extraction of the germanium from the crude material, it was necessary to develop a method for the quantitative determination of germanium. The procedure that was finally adopted is based directly upon the method of extraction that has already been described.

A weighed quantity, 20 to 100 g., of the germaniferous zinc oxide that had been dried at  $110^{\circ}$  is ground into a paste with water and is then poured into a flask that contains a solution of sodium hydroxide. These three substances are used in the proportions of 1 part of sodium hydroxide, 2 parts of the crude zinc oxide, and 5 parts of water. The flask is provided with a 3-hole rubber stopper through which are inserted a glass tube that reaches almost to the bottom of the flask, a small Vigreux distilling column, and a small separatory funnel. To the side arm of the Vigreux tube is fused a Liebig condenser, and a glass adapter is fused to the further end of the condenser. The receiver consists of an Erlenmeyer flask that is provided with a 2-hole rubber stopper. Through one of these holes passes the glass adapter which reaches to within a few millimeters of the bottom of the flask. A delivery tube is inserted through the other hole of the stopper and this tube is connected with a second Erlenmeyer flask. Water is placed in the first Erlenmeyer flask to a depth of 3 cm. and the second flask is half filled with water. The second flask serves as a check upon the completeness of the stoppage of germanium chloride in the first receiver. If any germanium is later found to have passed into the second flask, the determination is rejected. Both flasks are placed in a trough containing ice water.

In beginning the distillation a dish containing cracked ice is brought up under the distilling flask, and the apparatus is filled with chlorine which indicates that the contents of the flask has been saturated with the gas. Pure, conc. hydrochloric acid is next slowly introduced through the separatory funnel in amount sufficient to neutralize the sodium hydroxide that was originally employed and, in addition, to equal twice the weight of the crude zinc oxide that is being used. The passage of chlorine and the cooling of the flask are continued during the addition of the acid. When all of the acid has been introduced, the dish of cracked ice is replaced by an asbestos collar and the contents of the flask is then heated

in the manner already described. When  $\frac{1}{2}$  of the liquid has distilled over, an equal volume of conc. hydrochloric acid is run into the flask and the distillation is continued until  $\frac{1}{2}$  of the liquid has again passed over. The addition of hydrochloric acid and distillation of  $\frac{1}{2}$  of the liquid are once more repeated. The heating is then stopped and the two receivers are disconnected. Sulfuric acid is added to the contents of each to bring the acidity to 6 *N*, the flasks standing in ice during the addition of the acid. The liquid in each flask is then saturated with hydrogen sulfide and the flasks are stoppered and set aside for 24 hours. If the passage of the chlorine through the apparatus during the distillation has been slow, and if the receivers have been kept well cooled with ice, no germanium tetrachloride will pass over into the second receiver. A precipitate will, however, appear in the second flask because of the liberation of sulfur through the interaction of chlorine and hydrogen sulfide. The precipitate is tested spectrographically to ascertain whether it is free from germanium. If it is not, the determination is rejected. The precipitated germanium disulfide in the first flask is brought upon an ashless filter paper and the small amount of precipitate that adheres to the walls of the flask is loosened by means of a rubber "policeman" and brought upon the filter by rinsing with 3 *N* sulfuric acid that has been saturated with hydrogen sulfide. The whole precipitate is now washed with this liquid until the chlorides are removed. The germanium disulfide is then washed with alcohol to remove the sulfuric acid and is next dried. The bulk of the precipitate is removed from the filter and placed in a weighed porcelain crucible. It is moistened with nitric acid (1:1), the crucible is gently heated until the liquid has been driven off, is then allowed to cool, and conc. nitric acid is added. This is also driven off by gentle heating and the crucible is finally heated to dull redness.

Germanium dioxide that has been dried at 110° still contains an appreciable amount of water. Experiments performed in this laboratory by Miss K. M. Tressler, which will be described in a later article, have shown that complete dehydration is secured only when the dioxide is heated to 900°.

The filter paper is incinerated over a second weighed crucible. The product is black, due to the formation of some germanous oxide caused by the reduction of the germanium dioxide by the carbon of the paper. This is oxidized to the dioxide by treatment with nitric acid.

The filtrate from the precipitation of the germanium disulfide is set aside for 48 hours and the precipitate that then appears is treated in the same manner as the first precipitate. The sum of the weight of the dioxide in the two crucibles less the weight of the ash of the two filter papers gives the weight of the germanium calculated as dioxide that is present in the original sample.

Although no great accuracy is claimed for the method as thus far developed, two determinations in duplicate of the germanium in different samples of the crude zinc oxide gave concordant results.

Sample I.	I.	II.
Weight of sample, g. ....	50	75
GeO <sub>2</sub> found, g. ....	0.1235	0.1860
GeO <sub>2</sub> , %.....	0.247	0.248
Sample II.		
Weight of sample, g. ....	50	100
GeO <sub>2</sub> found, g. ....	0.0950	0.1885
GeO <sub>2</sub> , %.....	0.19	0.188

The completeness of the recovery of germanium from the crude zinc oxide by the method of extraction above described is evidenced by the fact that from a series of runs in which a total of about 10.7 kilograms of Sample I of the undried, crude oxide was used, 25.936 g. of pure germanium dioxide was obtained.

### The Non-Occurrence of Germanium in Samarskite.

Khrushchov<sup>14</sup> has stated that he had found germanium in American samarskite. This statement was published in the form of a report in the *Journal of the Russian Physical-Chemical Society*.<sup>15</sup> Literally translated it reads as follows.

"K. D. Khrushchov reports about finding germanium in columbium and tantalum minerals. American samarskite was heated in a 300g. platinum crucible for the purpose of comminuting the samarskite. After three heatings, the platinum was altered to such an extent that the crucible crumbled to a powder. On dissolving the platinum, a residue was obtained which resembled silica, but it was fairly difficultly soluble in hydrofluoric acid. Assuming the gelatinous sediment to be germanium dioxide, the reporter found that it was changed very easily by hydrogen to the black powder of germanium. Traces of germanium were also found in tantalite, fergusonite, columbite, gadolinite and in other minerals. American samarskite contains up to 1.5% of germanium. In view of the rarity of argyrodite the reporter calls attention to samarskite as an important source of germanium."

Lincio<sup>16</sup> failed to find evidence of the presence of germanium in samarskite. After the method for determining germanium that has been described in the preceding pages had been developed, the question of the occurrence of the element in American samarskite was taken up in this laboratory. Two hundred g. of finely-ground, selected samarskite was

<sup>14</sup> Khrushchov, *J. Russ. Phys. Chem. Soc.*, [1] 24, 30 (1892).

<sup>15</sup> We are indebted to the Library of Congress for a pen copy of this report. The translation here given was made by one of us (J. P.).

<sup>16</sup> Lincio, *Zentr. Min.*, 1904, 142.

fused with 1200 g. of potassium hydrogen sulfate. The fused mass was extracted with water and the residue, which contained a small quantity of undecomposed samarskite, was mixed with more potassium hydrogen sulfate and was fused and extracted with water as before. The two water extracts were combined and were evaporated to dryness.

The insoluble residue from the fusion was moistened with nitric acid and was then introduced into a Pyrex flask of 500cc. capacity. Two hundred cc. of hydrochloric acid was added and the mixture was subjected to distillation until 150 cc. of distillate had passed over. The distillate was saturated with hydrogen sulfide and was allowed to stand for 24 hours. The very slight precipitate that formed was collected on a small filter and was dried. The photograph of the arc spectrum of this material failed to show the presence of germanium.

The residue obtained from the water extracts of the fused material was moistened with nitric acid, and was introduced into a flask of 3 liters capacity. Fifteen hundred cc. of conc. hydrochloric acid was added and the mixture was distilled until about 600 cc. had passed over. Five hundred cc. of hydrochloric acid was then run into the flask and a second distillate of 400 cc. was obtained. The two distillates were united, were saturated with hydrogen sulfide and were allowed to stand for 24 hours. The slight precipitate that separated showed no spectrographic evidence of the presence of germanium.

Khrushchov's report is by no means convincing. He obtained a gelatinous residue which he assumed to be germanium dioxide, but he gives no reasons for this assumption and it is difficult to imagine what his reasons might have been. The fact that the material was darkened when heated in hydrogen might indicate the presence of a variety of compounds other than germanium dioxide. Moreover, it is probable that when he dissolved the platinum, he used aqua regia for this purpose. If he did so, all of the germanium would probably have been lost through volatilization of the germanium tetrachloride. It seems evident, therefore, that Khrushchov's experimental work does not justify his statement that samarskite contains germanium, and the results obtained by Lincio and in this laboratory would seem to show that that mineral does not carry detectable amounts of the element.

### Summary.

This article contains (1) the details of an experimental study of the extraction of germanium from germanium-bearing zinc oxide, and the preparation of pure germanium dioxide; (2) a description of a method for the determination of germanium; (3) the details of an examination of American samarskite which showed that the mineral does not contain germanium in an amount detectable by means of the spectroscope.

## HEAT OF WETTING OF SILICA GEL.

BY W. A. PATRICK AND F. V. GRIMM.

Received June 25, 1921.

The present investigation was undertaken with a view to ascertaining whether or not it was possible to account for the heat of wetting of silica gel on the basis of the changes of surface energy involved. There is available considerable experimental material,<sup>1,2,3</sup> relative to the heats of adsorption and wetting with adsorbents other than silica gel, and the interpretation of the results has been usually that of an effect due to the compression of the adsorbed liquids. The strongest evidence in favor of this view has been the fact that the heat of wetting by water was found to be negative between 0° and 4°.

Inasmuch as our ideas of the mechanism of adsorption have emphasized the attractive forces between the molecules of the adsorbed substance rather than that between the latter and the adsorbent, it was very difficult for us to accept the above explanation of the heat of wetting. We accordingly planned to measure the heats of wetting of silica gel by a number of liquids with a view to ascertaining whether the observed results were in accord with the involved changes in surface energy.

Fig. 1.

It was our belief that by using an adsorbent such as silica gel we could observe an easily measured heat of wetting by a material of definite and known composition. Furthermore inasmuch as the surface presented by such a gel is a water surface, we would be in a position to evaluate the changes in surface energy involved provided the interfacial surface tensions and their temperature coefficients were known.

The calorimeter used in these measurements was a 150cc. Dewar bulb fitted tightly with a hard rubber cover. Although the main portion of the heat of wetting developed within 5 minutes, nearly an hour was required for the calorimeter to give constant readings. For this reason it was thought best to carry out the measurements adiabatically. The calorimeter was accordingly placed in a wooden box which was provided with a fan for stirring the air, and

<sup>1</sup> Jungk, *Pogg. Ann.*, 125, 292 (1865).<sup>2</sup> Schwalbe, *Ann. Physik.*, 16, 32 (1905) (Bibliography).<sup>3</sup> Lamb and Coolidge, *THIS JOURNAL*, 42, 1146 (1920).

electric lamps for heating purposes. It was found that by working with a constant room-temperature of about one degree below that at which the measurement was made it was possible to keep the temperature of the air-bath to within  $0.01^\circ$  or  $0.02^\circ$  of the temperature of the calorimeter. By this arrangement the loss due to radiation was minimized.

The silica gel was placed inside the calorimeter before mixing with the liquid, thus insuring an initial constant temperature. The arrangement by means of which this was accomplished is best seen from the drawing (Fig. 1).

The vessel which contained the gel was provided with a carefully ground glass-stopper. Upon turning and lifting the glass rod sealed to the bottom of the vessel, the gel was thrown into the liquid. A glass hook attached to the stopper enabled the gel to be completely removed from the bottle.

A light stirrer made of glass and turned at a speed of about 500 r. p. m. gave very satisfactory results. A correction of from  $0^\circ$  to  $0.003^\circ$  per minute was applied to take care of the heat due to the stirring alone. The correction varied with the different liquids and was determined separately for each measurement.

The heating unit used for determining the thermal capacity of the calorimeter was constructed similarly to the one used by Tucker<sup>4</sup> in his heat of dilution experiments. It consisted of a Nichrome wire wound around a thin strip of mica and immersed in a thin-walled glass tube filled with oil. Copper leads were brazed on the resistance wire and the former alone extended out of the calorimeter.

A  $5^\circ$  Beckmann thermometer (not shown in Fig. 1) was used to read the temperature of the calorimeter and could be read to within  $0.002^\circ$ . A similar thermometer was placed in the air-bath.

The thermal capacity of the calorimeter was determined with the same charge in the calorimeter after a measurement of the heat of wetting by water had been made. Proceeding in this manner it was unnecessary to know the specific heat of the gel. An electric current from a storage battery was passed through the heating unit for a period of 5 minutes, the exact time being determined with a stop-watch. The resistance of the coil was determined and found to be 1.475 ohms. Current was measured with a milliammeter, readings being taken every 15 seconds. The thermal capacities of liquids other than water were calculated from their specific heats and densities. In all the experiments the same volume of liquid was used, namely, 50.07 cc. Furthermore, conditions were so arranged as to bring the final temperature to  $25^\circ$  in each measurement.

The heat of wetting by water was also determined between 0° and 4° and in all cases the results were positive. At 2.86° with 2.48 g. of gel the temperature increased to 3.92° within the first 5 minutes. Due to the fact that we did not try to make the calorimeter adiabatic, no effort was made to secure an exact value of the heat of wetting at this temperature.

With aniline the wetting was much slower and required about 2 hours before the temperature readings were constant.

### Discussion.

The fact that the heat of wetting by water between 0° and 4° was found to be positive is in itself considerable evidence against the compression theory of the heat of wetting.

There remains however the fact that a number of investigators have shown that the heat of wetting is negative between 0° and 4°. On closer examination it is evident that such experimentors were dealing with an effect of an entirely different order of magnitude. For example G. Schwalbe<sup>2</sup> in order to detect the small heats of wetting, employed a thermocouple and a galvanometer of such sensitivity that 1° change in temperature corresponded to  $1.86 \times 10^{-7}$  amp. In our opinion such investigations were not dealing with capillary adsorption at all, but were measuring the heat of adsorption on a plane surface. The initial film of adsorbed material is undoubtedly under compression, but the amount of liquid in such a state is negligible as compared with the condensation that occurs in a body exhibiting capillary structure.

It occurred to us that it might be possible to explain the above measurements from consideration of surface energy changes. Silica gel in our opinion consists of an agglomeration of silica nuclei, each particle being surrounded with an envelope of water. Therefore the gel may be regarded as exhibiting an enormous water surface which is the seat of considerable energy. When this material is immersed in water the above surface disappears due to the fact that a water-water interface cannot exist. When on the other hand, the gel is wetted by a liquid such as benzene the total surface undergoes no diminution in area, but the surface energy is greatly decreased due to the diminution of the interfacial tension. At the same time an amount of heat is set free equivalent to the decrease in surface energy, thus accounting for the heat of wetting.

Inasmuch as the total surface energy is given by the following expression

$$E = \omega \sigma - T \frac{d\sigma}{dt} \omega$$

where  $\omega$  is the surface and  $\sigma$  the surface tension, it is first necessary to ascertain whether the surface of one gram of silica gel is of sufficient magnitude to account for the measured heat effects. The surface tension of water at 25° is according to Harkins and Cheng<sup>3</sup> 72.05 dynes per cm., and the value of  $d\sigma/dt = -0.1511$ . Therefore  $E$  at 25° equals 117.08 ergs per cm<sup>2</sup>. In order to obtain a heat of wetting of 19.22 cal. per gram of gel it is necessary that the latter exhibit a surface of -

<sup>3</sup> W. D. Harkins and Y. C. Cheng, *THIS JOURNAL*, 43, 35 (1921).

$$\omega = \frac{19.22 \times 4.182 \times 10^7}{117.08} = 6.9 \times 10^6 \text{ cm.}^2$$

This figure is in good agreement with the ultra-microscopically observed degree of heterogeneity; Zsigmondy observing particles of the order of 5  $\mu\mu$  in diameter. Assuming roughly the density of the gel particles to be 2 it is evident that the surface exhibited by 1 g. of particles of the above size would be

$$\frac{3 \times 0.5}{2.5 \times 10^{-7}} = 6 \times 10^6 \text{ cm.}^2$$

It is evident from such a calculation that the surface energy is therefore sufficient to explain the observed heat effects.

There still remains to be tested the agreement between the calculated and measured values of the heat of wetting by the other liquids. In the calculation of the heat of wetting, the surface of the gel is assumed to be the same as that evaluated from the heat of wetting by water.

In the case of benzene, for example, the total surface energy after wetting is

$$E = \omega\sigma' - \omega T \frac{d\sigma'}{dt}$$

where  $\sigma'$  = the interfacial tension at the water-benzene surface. The heat of wetting by benzene is equal to the difference between the total surface energy of the gel and the above expression. Using the value given by Harkins for the free surface energy and its variation with the temperature, the total surface energy of 1 cm.<sup>2</sup> of a water-benzene interface at 25° is evaluated as 51.66 ergs per cm.<sup>2</sup>. Inasmuch as a water surface at the same temperature possesses 117.08 ergs per cm.<sup>2</sup>, it is evident that during the wetting 117.08–51.66 or 65.42 ergs per cm.<sup>2</sup> must have been converted into heat. Furthermore, if in the case of wetting by water the final surface energy was reduced to zero, then the heat of wetting by benzene should be in the ratio of 65.42:117.08 to that of the heat of wetting by water, or equal to 10.74 cal. per g. of gel. The heat of wetting observed was, 11.13 cal. per g.

In a similar manner it may be calculated using the data of Harkins that the total interfacial energy of a water-carbon tetrachloride surface at 25° is equal to 73.86 ergs per cm.<sup>2</sup>. From this value we calculated that the heat of wetting by carbon tetrachloride should be 7.10 cal. per g; the observed was 8.42 cal. per g.

In the case of aniline no data are available as to the variation of the free interfacial energy with the temperature, and evaluation of the latent surface energy is uncertain. However, we may approximate this value as follows. The interfacial tension of water-aniline at 20° is given by Harkins as 5.77 dynes per cm. The critical solution temperature of these two liquids is 167°, at which point the interfacial tension must be zero.

By assuming a straight line temperature function we therefore obtain  $d\sigma'/dt = -0.04$ . The bound surface energy at  $25^\circ$  is then found to be 11.92 ergs per  $\text{cm.}^2$  which added to the free energy gives a total surface energy of 17.69 ergs per  $\text{cm.}^2$  for the water-aniline interface. The heat of wetting by aniline may then be calculated to equal 16.56 cal. per g; the observed, was 17.54 cal. per g.

In all cases it is noted that our calculated heats of wetting are lower than the observed values, although the agreement is remarkable considering the nature of the calculations. The discrepancy is, however, easily accounted for, although unfortunately we are not able to reduce our corrections to a quantitative basis. It has been shown by Davidheiser and Patrick<sup>6</sup> that silica gel contains a certain amount of acid. Furthermore it is known that acids decrease the interfacial tension at the water-benzene boundary. In other words it is decidedly probable that the total surface energy after wetting is lower than that calculated. Furthermore it is possible that the surface energy of the gel is greater than that assumed by us, due to the fact that the adsorbed water layer exhibits a higher surface tension than does ordinary water. Both of these effects would tend to increase the heat of wetting; in our opinion, however, the lowering of the interfacial tension due to the presence of acid is sufficient to account for the entire difference between the measured and calculated values.

In the case of alcohol, at first thought we should expect the heat of wetting to be equal to the heat of wetting by water inasmuch as the water and alcohol are miscible in all proportions. The observed heat of wetting, however, is found to be 3.41 cal. per g. higher than that for water. This difference is too great to be explained on the basis of heat of solution of water in alcohol.

The ideas upon which our explanation is based will be developed in more detail in a paper under preparation dealing with the effect of capillarity upon equilibrium. Nevertheless it may be said at this time that it is conceivable that in a small capillary tube water may present a surface against alcohol. Furthermore if such a surface were to possess a positive temperature coefficient of free surface energy, we should then expect the heat of wetting by alcohol to be greater than that of water. For example the heat of wetting of silica gel by heptin may be calculated from the interfacial data of Harkins. According to the latter the total surface energy of a heptin-water surface at  $20^\circ$  equals  $-19.60$  ergs per  $\text{cm.}^2$ . We should therefore expect this liquid to exhibit a higher heat of wetting than water, namely 22.4 cal. per g. of gel.

### Summary.

1. The heats of wetting of silica gel by water, benzene, carbon tetrachloride, ethyl alcohol and aniline have been determined.

<sup>6</sup> Davidheiser and Patrick, to be published later.

2. The heat of wetting of silica gel by water has been found to be positive between  $0^{\circ}$  and  $4^{\circ}$ .

3. The observed heats of wetting have been satisfactorily accounted for on the basis of surface energy changes.

## THE TRANSFERENCE NUMBERS OF SULFURIC ACID BY THE CONCENTRATION CELL METHOD.

BY ALFRED L. FERGUSON AND WESLEY G. FRANCE.

Received June 28, 1921.

The concentration cell method for the determination of transference numbers was shown, in this laboratory<sup>1</sup> to be more accurate in the case of uni-univalent electrolytes than the Hittorf method. In the present investigation it is found to apply equally well in the case of the uni-bivalent electrolyte  $\text{H}_2\text{SO}_4$ .

The determination involves the measurement of the potentials of a concentration cell without diffusion; a concentration cell with diffusion and reversible with respect to the cation; and a concentration cell with diffusion and reversible with respect to the anion.

The total potential of the concentration cell, reversible with respect to the cation,  $\text{Pt}_\text{H} | \text{H}_2\text{SO}_4 \text{ } c_1 | \text{H}_2\text{SO}_4 \text{ } c_2 | \text{Pt}_\text{H}$ , consists of the algebraic sum of the two electrode potentials and the potential at the boundary of the solutions. On the assumption that sulfuric acid dissociates into two hydrogen ions and one sulfate ion, the algebraic sum of the electrode potentials is expressed by the well-known formula

$$E_1 = \frac{RT}{F} \ln \frac{c_1}{c_2}. \quad (1)$$

The potential at the liquid boundary is expressed by the formula

$$E_B = \frac{2U_c - U_a}{2(U_c + U_a)} \frac{RT}{F} \ln \frac{c_1}{c_2}. \quad (2)$$

The hydrogen electrode in the concentrated solution is positive with respect to the hydrogen electrode in the dilute solution. At the boundary of the solutions, the sulfuric acid diffuses from the concentrated to the dilute side, and since the hydrogen ion moves faster than the sulfate ion, the dilute side is positively charged with respect to the concentrated. This means that the potential developed at the boundary opposes the potential of the hydrogen electrodes. The total potential of the hydrogen concentration cell is, therefore, expressed by the equation

<sup>1</sup> A. L. Ferguson, *J. Phys. Chem.*, 20, 326 (1916).

$$E_1 - E_B = E_2 = \frac{RT}{F} \ln \frac{c_1}{c_2} - \frac{2U_c - U_a}{2(U_c + U_a)} \frac{RT}{F} \ln \frac{c_1}{c_2}$$

$$= \left[ 1 - \frac{2U_c - U_a}{2(U_c + U_a)} \right] \frac{RT}{F} \ln \frac{c_1}{c_2} = \frac{3}{2} \frac{U_a}{U_c + U_a} \frac{RT}{F} \ln \frac{c_1}{c_2}.$$

By the substitution of the transference number of  $N_a$ , of the anion for  $U_a/(U_a + U_c)$  the equation

$$E_H = \frac{3}{2} N_a \frac{RT}{F} \ln \frac{c_1}{c_2} \quad (3)$$

is obtained.

The total potential of the concentration cell, reversible with respect to the anion,  $\text{Hg} | \text{Hg}_2\text{SO}_4, \text{H}_2\text{SO}_4 \text{ } c_1 | \text{H}_2\text{SO}_4 \text{ } c_2, \text{Hg}_2\text{SO}_4 | \text{Hg}$ , consists of the algebraic sum of the two electrode potentials and the potential at the boundary of the solutions. The algebraic sum of the electrode potentials is expressed by the formula

$$E_A = \frac{RT}{2F} \ln \frac{c_1}{c_2} \quad (4)$$

The boundary potential is the same as in the hydrogen concentration cell, and is in the same direction. The algebraic sum of the sulfate electrode potentials is also in this direction. Therefore the total potential of the sulfate concentration cell is expressed by the equation

$$E_A + E_B = E_{\text{SO}_4} = \frac{RT}{2F} \ln \frac{c_1}{c_2} + \frac{2U_c - U_a}{2(U_c + U_a)} \frac{RT}{F} \ln \frac{c_1}{c_2}$$

$$= \left[ \frac{1}{2} + \frac{2U_c - U_a}{2(U_c + U_a)} \right] \frac{RT}{F} \ln \frac{c_1}{c_2} = \frac{3}{2} \frac{U_c}{U_c + U_a} \frac{RT}{F} \ln \frac{c_1}{c_2}.$$

By the substitution of the transference number,  $N_c$ , of the cation for the expression  $U_c/(U_a + U_c)$  the equation becomes

$$E_{\text{SO}_4} = \frac{3}{2} N_c \frac{RT}{F} \ln \frac{c_1}{c_2} \quad (5)$$

The potential of the concentration cell without diffusion,  $\text{Pt}_H | 0.1 \text{ } M \text{ } \text{H}_2\text{SO}_4, \text{Hg}_2\text{SO}_4 | \text{Hg} | \text{Hg}_2\text{SO}_4, 0.01 \text{ } M \text{ } \text{H}_2\text{SO}_4 | \text{Pt}_H$ , is represented by the equation

$$E = \frac{3}{2} \frac{RT}{F} \ln \frac{c_1}{c_2} \quad (6)$$

The value  $E$  may be obtained experimentally from the difference between the potentials of the cells  $\text{Pt}_H | 0.1 \text{ } M \text{ } \text{H}_2\text{SO}_4, \text{Hg}_2\text{SO}_4 | \text{Hg}$ , and  $\text{Pt}_H | 0.01 \text{ } M \text{ } \text{H}_2\text{SO}_4, \text{Hg}_2\text{SO}_4 | \text{Hg}$ .

Equation 5 divided by Equation 6 gives  $E_{\text{SO}_4}/E = N_c$ , which expresses the transference number of the cation in terms of  $E_{\text{SO}_4}$  and  $E$ . In a similar way the expression  $E_H/E = N_a$ , is obtained, as  $N_a + N_c = 1$ , therefore  $E_{\text{SO}_4}/E + E_H/E = 1$ ; and

$$E_{\text{SO}_4} + E_H = E. \quad (7)$$

It is evident from Equation 7 that the same value should be obtained

by the sum of the potentials  $E_{\text{SO}_4}$  and  $E_{\text{H}}$  as by the difference of the potentials  $E_{0.01}$  and  $E_{0.1}$ .

Since, to obtain the total potential,  $E_{\text{SO}_4}$ , the boundary potential is added to the electrode potentials, while for the total potential,  $E_{\text{H}}$ , it is subtracted, then, by a combination of these as shown below, a formula is obtained which expresses the boundary potential in terms of  $E_{\text{SO}_4}$  and  $E_{\text{H}}$ .

$$\begin{aligned} E_{\text{H}} &= \frac{RT}{F} \ln \frac{c_1}{c_2} - \frac{(2-3N_a)RT}{2} \ln \frac{c_1}{c_2}; E_{\text{SO}_4} = \frac{RT}{2F} \ln \frac{c_1}{c_2} + \frac{(2-3N_a)RT}{2} \ln \frac{c_1}{c_2}; \\ 2E_{\text{SO}_4} &= \frac{RT}{F} \ln \frac{c_1}{c_2} + \frac{2(2-3N_a)RT}{2} \ln \frac{c_1}{c_2} \\ \frac{2E_{\text{SO}_4} - E_{\text{H}}}{3} &= \frac{(2-3N_a)RT}{2} \ln \frac{c_1}{c_2}. \end{aligned} \quad (8)$$

Therefore the value for the boundary potential may be obtained by the substitution of the measured potentials  $E_{\text{SO}_4}$  and  $E_{\text{H}}$  in the above equation.

### Apparatus and Materials.

The potential measurements were made with an Otto Wolff 15,000-ohm potentiometer, using a certified Weston cell as a standard. The solutions were prepared from a commercial c. p. sulfuric acid of 1.84 sp. gr. and were standardized by means of sodium carbonate prepared by the fusion of c. p. sodium hydrogen carbonate in an atmosphere of carbon dioxide. The mercurous sulfate was electrolytically prepared by the Hulett<sup>2</sup> method. The hydrogen was obtained by the electrolysis of 5 *N* sodium hydroxide solution using a generator similar to that of Bodenstein and Pohl,<sup>3</sup> and the hydrogen electrodes were of the ordinary foil type. The mercury used was twice distilled. All measurements were made with the cells contained in an electrically heated and regulated oil thermostat maintained at a constant temperature of 25°.

The concentration cell method, as previously shown, requires the consecutive measurement of 4 distinct potentials which must be extremely constant and reproducible. Much experimental work was required before the satisfactory system of cells shown in Fig. 1 was developed. In this arrangement the connections, between the separate cells, are made by means of siphons (M, N, H and G). A method whereby they could be filled with the proper solutions before being connected with the arms of the containers was considered essential. In this way new boundaries could be introduced without disturbing the electrodes. Connections were made with the cells through the reservoirs ( $R_a$ ,  $R_b$ ,  $R_c$ ,  $R_d$ , Fig. 1) on the arms of the containers.

<sup>2</sup> Hulett, *Phys. Rev.*, **32**, 257 (1911).

<sup>3</sup> Bodenstein and Pohl, *Z. Elektrochem.*, **11**, 373 (1905).

## Arrangement of Cells and Method of Procedure.

In Fig. 1, A and B are the mercurous sulfate electrodes; C and D are the hydrogen electrodes. A and C contain 0.1 *M* and B and D 0.01 *M* sulfuric acid. The electrodes A and C are connected by the siphon H, B and D by the siphon G. The two sulfate electrodes are connected by the siphon M; the two hydrogen electrodes by the siphon N.

The containers were fastened in their proper position and filled with the electrode materials. The siphons H and G were put in place and filled by suction. The stopcocks J and O, P and K were then closed. The hydrogen was admitted to C and D through the inlets S and S' and bubbled through the solutions. It escaped through the outlets W and W' into

Fig. 1.—Arrangement of cells as used.

chambers (not shown) of about 10 cc. capacity. When the hydrogen electrodes became constant, the stopcock O was opened long enough to measure the potential  $E_{0.1}$  between the sulfate and hydrogen electrodes in 0.1 *M* sulfuric acid solution. In a similar way the measurement  $E_{0.01}$  was made for the sulfate and hydrogen electrodes in 0.01 *M* sulfuric acid. By the proper manipulation of the stopcocks, the solutions in those halves of siphons H and G connected to the sulfate electrodes were emptied. The arms of the siphons M and N with the rubber stoppers attached were immersed in 2 beakers which contained 0.1 *M* and 0.01 *M* sulfuric acid. The solutions were drawn into the arms of the siphons and formed the boundary within the stopcocks t and q. These siphons were then placed

in their proper positions connecting the cells.<sup>4</sup> The stopcock  $q$  was opened and the potential  $E_H$  of the hydrogen concentration cell measured. In a similar way the potential of the sulfate concentration cell ( $E_{SO_4}$ ) was measured.

The leads from the electrodes were permanently connected to a switch-board so the potentials between any two electrodes could be measured by the manipulation of a switch connected to the potentiometer.

In the first part of the work the measurements showed considerable fluctuation, which was traced to the leakage of current from the high potential electrical circuits in connection with the thermostat. The difficulty was overcome by the replacement of the water by kerosene.

During the development of this work some information was obtained which may be of assistance to others concerned with similar investigations. It was found that the length of time required for the mercurous sulfate electrodes to reach a condition of equilibrium could be greatly reduced by vigorously shaking the sulfuric acid and mercurous sulfate in a mechanical shaker before using in the cells. The first cells constructed contained the hydrogen electrodes in the same chamber as the mercurous sulfate electrode and the potentials were found to vary greatly. This was believed to be due to the catalytic effect of the platinum black which was loosened by the action of the hydrogen on the electrode and fell on to the mercurous sulfate. The difficulty was eliminated by the use of separate chambers for the electrodes.

The final measurements were made and are given in four tables of which I and II are examples.

In the following tables Col.  $E_H$  contains the potentials of the hydrogen concentration cell with diffusion,  $Pt_H | 0.1 M H_2SO_4 | 0.01 M H_2SO_4 | Pt_H$ ;

The cell was set up at 11 P.M. on October 14, 1919.

Col.  $E_{\text{SO}_4}$  those of the sulfate concentration cell with diffusion,  $\text{Hg} | \text{Hg}_2\text{SO}_4$  0.01  $M$   $\text{H}_2\text{SO}_4$  | 0.1  $M$   $\text{H}_2\text{SO}_4$ ,  $\text{Hg}_2\text{SO}_4 | \text{Hg}$ ; Col.  $E_{0.1}$  the potentials of the cell,  $\text{Pt}_\text{H} | 0.1 M \text{H}_2\text{SO}_4$ ,  $\text{Hg}_2\text{SO}_4 | \text{Hg}$ ; and Col.  $E_{0.01}$  the potentials of the cell,  $\text{Pt}_\text{H} | 0.01 M \text{H}_2\text{SO}_4$ ,  $\text{Hg}_2\text{SO}_4 | \text{Hg}$ . The column headed " $E$  by  $E_\text{H} + E_{\text{SO}_4}$ " contains the sums of the values recorded in Cols.  $E_\text{H}$  and  $E_{\text{SO}_4}$ . The column " $E$  by  $E_{0.01} - E_{0.1}$ " contains the differences between the values recorded in  $E_{0.01}$  and  $E_{0.1}$ .

The 0.1  $M$  and 0.01  $M$  cells were prepared and placed in the thermostat where they remained for about 12 hours to come to equilibrium before the boundaries were introduced. This accounts for the blank spaces in the tables.

As pointed out in the theoretical discussion the values recorded in column  $E_\text{H} + E_{\text{SO}_4}$  should be equal to those recorded in column  $E_{0.01} - E_{0.1}$ . The close agreement of these values indicates the accuracy of the potential measurements. The differences between the successive values in each column indicates the degree of constancy of the cells. The differences in columns  $E_{0.01}$  and  $E_{0.1}$  may be attributed, in part, to changes in barometric pressure, for which corrections have not been applied, as such corrections are unnecessary for the calculations in which the measurements are used.

The remarkable agreement between the averages in the different tables indicates the reproducibility of the work.

In the theoretical treatment formulas were given by means of which the values of  $E$ ,  $E_\text{H}$ ,  $E_{\text{SO}_4}$  and  $E_\text{B}$  can be calculated. Table III contains a summary of such calculated values together with the measured values.

TABLE III.—COMPARISON BETWEEN CALCULATED AND MEASURED POTENTIALS.

These calculations involve the ratio  $\alpha_1 C_1 / \alpha_2 C_2$ . It has been customary to use conductivity values in its calculation: Since the work of Jones

is probably the most reliable on the conductivity of sulfuric acid, his results were used in these calculations. This ratio may also be obtained from freezing-point data. The values obtained from these two sources are decidedly at variance. No freezing-point data are available for the degree of dissociation of 0.1 *M* sulfuric acid. However, a complete table is given by Lewis and Linhart<sup>5</sup> for concentrations between  $10^{-2}$  and  $10^{-6}$  molar. The degree of dissociation given by Lewis and Linhart for 0.01 *M* sulfuric acid was substituted in the equation for *E* together with the measured potential (0.06054), and the equation solved for the degree of dissociation for 0.1 *M* sulfuric acid. In the curve of Fig. 2

Fig. 2.—Dissociation-concentration curve.

the abscissas are the molar concentrations and the ordinates the degrees of dissociation. The portion indicated by the solid line was obtained from the freezing-point data and the broken portion is an extension to include the value calculated from the potential measurements. Since this is a smooth curve, the indication is that the point obtained from the potential measurements is approximately the same as would have been obtained from the freezing-point determination. In every instance the results obtained when the freezing-point values are used in the ratio  $\alpha_1 C_1 / \alpha_2 C_2$  show better agreement with the measured potentials than when the conductivity values are used. The latter results are in all cases higher than the measured. It should be noticed,

however, that the exact agreement between the measured and calculated values for *E* is to be expected, since it was from this measured value of *E* that  $C_2$  was calculated. The close agreement between the measured and calculated values of  $E_H$ ,  $E_{SO_4}$ , and  $E_B$  is a true indication of the correctness of the value 0.2973 for the degree of dissociation of 0.1 *M* sulfuric acid.

<sup>5</sup> Lewis and Linhart, *THIS JOURNAL*, 41, 1959 (1919).

the sulfuric acid dissociates almost entirely into 3 ions at these concentrations.

It has been noticed by others that the calculated values for potential measurements are always higher than the measured values when conductivity dissociation ratios are used. Ferguson<sup>1</sup> in his work on hydrochloric acid attributed the difference to the fact that the formula assumes the complete dissociation of the acid. As the acid is not completely dissociated the formula does not exactly represent the facts and must be corrected so as to include the undissociated acid. Such a correction was made for hydrochloric acid and, when applied to the formulas involving conductivity ratios, gave values which agreed more closely with those measured. A similar correction can be developed for the sulfuric acid concentration cell.

When two faradays of electricity pass through a sulfuric acid concentration double cell, one mol of acid is transferred from one concentration to the other. The electrical work which accompanies this change is represented by  $W = 2 EF$ . The osmotic work required to effect this same change is usually represented by  $W = 3 RT \ln c_1/c_2$ . This assumes that the acid is completely dissociated into 3 ions. Since it is not completely dissociated what actually happens is (1) the transference of an amount of hydrogen ion equal to twice the concentration times the dissociation of the acid; (2) the transference of an amount of sulfate ion equal to the concentration times the dissociation of the acid; (3) the transference of an amount of undissociated acid equal to the concentration of the undissociated acid. The general expression which represents the sum of the osmotic work in (1) and (2) is  $W_1 = \alpha 3RT \ln \frac{c_1}{c_2}$ .

Similarly the osmotic work in (3) is  $W = (1-\alpha)RT \ln \frac{c_1}{c_2}$ . In the application to sulfuric acid ( $c_1$ ) in ( $W_1$ ) becomes  $2c_1H^+ = 2c_1\alpha' = c_1SO_4^{--}$ ; and  $c_2$  becomes  $2c_2H^+ = 2c_2\alpha'' = c_2SO_4^{--}$ .

Similarly  $c_1$  in  $W_2$  becomes  $c_1H_2SO_4 = c_1(1-\alpha')$ ; and  $c_2$  becomes  $c_2H_2SO_4 = c_2(1-\alpha'')$ ; and, as the total electrical work is equal to the total osmotic work,

$$W = 2EF = \alpha 3RT \ln \frac{c_1\alpha'}{c_2\alpha''} + (1-\alpha) RT \ln \frac{c_1(1-\alpha')}{c_2(1-\alpha'')}$$

$$E = \alpha \frac{3}{2} \frac{RT}{F} \ln \frac{c_1\alpha'}{c_2\alpha''} + \frac{(1-\alpha)}{2} \frac{RT}{F} \ln \frac{c_1(1-\alpha')}{c_2(1-\alpha'')}$$

This formula cannot be taken as absolutely correct since it assumes that the dissociation is the same in both concentrations, which is not true.

The most reliable value that can be used for  $\alpha$  is  $\frac{\alpha' + \alpha''}{2}$ , in which  $\alpha$  is the degree of dissociation in  $c_1$  and  $\alpha''$  is the degree of dissociation in  $c_2$ .

Col.  $E''$  Table III shows the result of the application of this correction. It is evident that the correction is an improvement since the difference (0.00639) between the measured value and that calculated from the corrected formula is much less than the difference (0.01829) between the measured value and that calculated from the usual formula.

In the theoretical part of this work it was shown that the boundary potential can be calculated from the formula  $E_B = \frac{2-3}{2} \frac{N_a}{F} \frac{RT}{F} \ln \frac{c_1}{c_2}$ , also that  $E_B = \frac{2E_{\text{SO}_4} - E_H}{3}$ . Column  $E_B$  contains the results from the calculation by the first formula. Again the close agreement between the measured and calculated values in the case of the freezing-point ratio and lack of agreement in the case of the conductivity ratio are evident.

MacInnes<sup>6</sup> has developed a formula for boundary potentials of uni-univalent electrolytes which involves the transference number of the cation and the potentials of the cells with and without diffusion. He states that it "contains no assumption regarding the concentration of the ions of the solutions." In the following development the same reasoning is applied to the uni-bivalent acid, sulfuric acid, on the assumption that it dissociates into two hydrogen ions and one sulfate ion.

When two faradays of electricity pass through the cell the net result is the transference of one mol of sulfuric acid from the concentrated to the dilute side. The current is carried across the boundary between the two solutions by the transference of  $2N_c$  gram ions of hydrogen ions in one direction and  $1 - N_c$  gram ions of sulfate ions in the opposite. The osmotic work at the boundary is proportional to the algebraic sum of the number of gram ions that have passed through it. Therefore the osmotic work  $W$  is proportional to  $3N_c - 1$ . The electrical work which accompanies the transference of one mol of sulfuric acid from the concentrated to the dilute side is equal to the product of the electromotive force of the cell and the number of faradays required to effect the transference. Since this is so, the following relation holds.

$$2EF:2E_B F::3:3N_c-1$$

and  $E_B = E(3N_c - 1)/3$ ; for  $E$ ,  $\frac{E_{\text{SO}_4}}{N_c}$  may be substituted, since it has been shown that  $N_c = \frac{E_{\text{SO}_4}}{E}$ . The formula then becomes

$$E_B = E_{\text{SO}_4} (3N_c - 1) / 3N_c.$$

Substituting the correct values for  $N_c$  and  $E_{\text{SO}_4}$  as measured, the value 0.02904 is obtained. This is in almost perfect agreement with the measured value 0.02906 and proves the validity of the formula.

<sup>6</sup> MacInnes, *THIS JOURNAL*, 37, 2301 (1915).

That this expression  $E_B = E_{\text{SO}_4} (3N_c - 1) / 3N_c$  is but another form of the usual expression  $E_B = \frac{2-3N_a}{2} \frac{RT}{F} \ln \frac{c_1}{c_2}$  for boundary potential, can readily be shown, since

$$E_B = \frac{E_{\text{SO}_4}}{3N_c} (3N_c - 1) \quad (9)$$

and

$$E_{\text{SO}_4} = N_c \frac{3}{2} \frac{RT}{F} \ln \frac{c_1}{c_2}.$$

Substituting in (9)

$$E_B = \frac{N_c \frac{3}{2} \frac{RT}{F} \ln \frac{c_1}{c_2}}{3N_c} (3N_c - 1) = \frac{RT}{F} \ln \frac{c_2}{c_1} (3N_c - 1)$$

is obtained; as  $(3N_c - 1) = (2 - 3N_a)$

$$E_B = \frac{RT}{F} \ln \frac{c_1}{c_2} (3N_c - 1) = \frac{2 - 3N_a}{2} \frac{RT}{F} \ln \frac{c_1}{c_2}.$$

Therefore

$$E_B = \frac{E_{\text{SO}_4}}{3N_c} (3N_c - 1) = \frac{2 - 3N_a}{2} \frac{RT}{F} \ln \frac{c_1}{c_2} = \frac{2E_{\text{SO}_4} - E_H}{3}.$$

A consideration of these formulas indicates the advantage of the formula  $(2E_{\text{SO}_4} - E_H)/3$  since it contains no assumption regarding the concentration of the ions, nor does it require a knowledge of the transference numbers.

The averages of  $E_H$ ,  $E_{\text{SO}_4}$ , and  $E$  from a few of the tables obtained are contained in Table IV, together with the transference numbers calculated from them.

TABLE IV.  
SUMMARY OF POTENTIALS AND TRANSFERENCE NUMBERS.

Table.	$E_H$ .	$E_{\text{SO}_4}$	$\frac{E \text{ or } E_{0.01}-E_{0.1}}{E_{0.01}-E_{0.1}}$	$\frac{N_a}{E_H/E}$	$\frac{N_a}{1-E_{\text{SO}_4}/E}$
II	0.01136	0.04922	0.06056	0.1875	0.1875
III	0.01126	0.04923	0.06047	0.1862	0.1862
IV	0.01137	0.04929	0.06059	0.1875	0.1874
V	0.01126	0.04927	0.06053	0.1868	0.1868
Av.	0.01131	0.04925	0.06054	0.1868	0.1868

To facilitate the comparison of the value obtained in this investigation with those obtained in others, a summary of such values is contained in Table V.

Attention should be called to the fact that the values recorded in columns  $E_H/E$  and  $1 - E_{\text{SO}_4}/E$  of Table IV are determined from separate and distinct potential measurements. The agreement between the successive values in each column and between the averages of the two columns demonstrates the reliability of the concentration cell method for the determination of the transference numbers of sulfuric acid.

### Summary.

1. A method has been described for the determination of the transference numbers of a uni-bivalent electrolyte by the measurement of the potentials of concentration cells.

2. The transference number of the anion of sulfuric acid for concentrations between 0.1 *M* and 0.01 *M* has been measured and found to be  $0.1868 \pm 7$  at 25°.

3. It has been shown that dissociation values determined from freezing-point data are more satisfactory for calculating the potentials of concentration cells than those obtained from conductivity data.

4. A correction to the formula for the potential of a concentration cell has been developed which takes into account the undissociated part of the acid.

5. It has been shown that the concentration-cell method is entirely satisfactory for the determination of the transference numbers of sulfuric acid.

ANN ARBOR, MICHIGAN.

<sup>1</sup> The values and the limits of accuracy of the first six investigations are taken from MacBain's abstract of transference data (*J. Wash. Acad. Sci.*, 9, 11 (1905)). In the first six investigations the analytical method was employed. According to MacBain the results of Jahn and Huybrechts and of Tower are probably the most reliable. Whetham and Paine employed the conductivity method. The values in the last column were obtained from the values in the preceding column by the application of the temperature coefficients given by Tower (*THIS JOURNAL*, 26, 1038 (1904)).

## THE INFLUENCE OF GELATIN ON THE TRANSFERENCE NUMBERS OF SULFURIC ACID.

BY ALFRED L. FERGUSON AND WESLEY G. FRANCE.

Received June 28, 1921.

The properties of hydrophile colloids have been the subject of many investigations during the past few years. So far, no entirely satisfactory explanation has been offered for their action in the presence of electrolytes. The theories advanced are based largely on the measurements of osmotic pressure, conductivity, swelling and transference numbers.

There appear to be but three articles in the literature dealing with the influence of colloids on transference numbers and in each instance the analytical method was used.

Paul Richter<sup>1</sup> investigated the influence of gelatin, gum arabic, agar-agar, and peptone on the transference number of the chloride ion of lithium, potassium and hydrogen chlorides.

A. Mutscheller<sup>2</sup> investigated the influence of gelatin on the transference numbers of silver nitrate, cupric sulfate and zinc sulfate solutions which contained definite quantities of a 1% gelatin solution.

According to his results the transference numbers of the nitrate and sulfate ions decrease with an increase in the quantity of gelatin solution added. By the addition of sufficient quantities of gelatin solution, even negative values were obtained. He states that when the transference number of the anion is zero the conditions are most favorable for the deposition of the metal. The effect of the gelatin is accounted for on the assumption that it is positively charged and forms an "absorption compound" with the anions. This results in the partial or complete neutralization or even reversal of the original charge on the ions. The results obtained by Mutscheller for the sulfate and nitrate ions show effects of gelatin far in excess of those observed by Richter for the chloride ion.

It is well to emphasize here that the results obtained by Mutscheller, if correct, are indeed remarkable, but it is the opinion of the authors that an error has been made in the calculations or in the recorded data. This subject is under investigation at the present time.

In an earlier article<sup>3</sup> the authors described in detail the application of the concentration cell method to the determination of the transference numbers of sulfuric acid and demonstrated its reliability. The method lends itself admirably to the determination of the influence of gelatin on the transference numbers of sulfuric acid. In that article it was also

<sup>1</sup> Richter, *Z. physik. Chem.*, **80**, 449 (1912).

<sup>2</sup> Mutscheller, *Met. Chem. Eng.*, **13**, 353 (1915); *THIS JOURNAL*, **42**, 442 (1920).

<sup>3</sup> Ferguson and France, *THIS JOURNAL*, **43**, 2150 (1921).

pointed out that the boundary potential is an important factor in the determination of transference numbers by the concentration-cell method.

Mutscheller<sup>2</sup> explains the effect of gelatin on the transference numbers of silver nitrate, cupric sulfate and zinc sulfate by the assumption that gelatin is positively charged and "absorbs" the negative ions. This causes a decrease in their velocity. According to Nernst the potential at the boundary of two solutions of different concentration depends upon the difference in velocities of the ions. If the theory of Mutscheller is true the presence of gelatin in such solutions should change the boundary potential. Then measurements of the transference numbers of sulfuric acid by this method would determine whether gelatin affected the boundary potential.

Since gelatin precipitates the heavy metals, it was obvious that precipitation would result if it were added to a sulfuric acid solution saturated with mercurous sulfate. Since, however, the influence of the gelatin on transference numbers is due only to its effect on the boundary potential, it is unnecessary to introduce gelatin into the electrode containers.

The cells were prepared as described in the previous article and the siphons connecting the hydrogen and sulfate electrodes were filled with 0.1 *M* and 0.01 *M* solutions of sulfuric acid which contained a definite concentration of gelatin. They were then placed in the reservoirs, with the ends immersed in solutions of the same concentration as that which surrounded the electrodes.

The measurements were made as before, but showed a gradual progressive change. It was discovered that this was due to the diffusion of the gelatin from the siphons into the reservoirs and then into the solution which surrounded the electrodes. This made it necessary to devise a method which would prevent the diffusion and at the same time introduce no new potentials. Several devices were tried in which use was made of glass wool, filter paper, glass capillaries, and cotton wicks, before the following satisfactory method was found.

Fig. 1.—Detail of reservoir.

and so filled that the solution rose in the inner tube to the level *L*, indicated in Fig. 1. Gelatin solution identical with that in the siphon *S* was filled in the reservoirs to the level *L*. A wick *W* previously saturated with acid solution containing no gelatin was hung over the side of the inner tube so that one end of it was immersed in the plain solution of the inner tube and the other in the gelatin solution in the reservoir. This arrangement effectively eliminated the

diffusion, provided the solutions in the inner tube and in the reservoir were maintained at the same level. No new potentials were introduced by this arrangement. All of the measurements were made with cells prepared in this manner. Measurements were made with concentrations of gelatin over a range of 0.5 to 20.0%. The results of these measurements are contained in 18 tables of which Table I is a sample.

The cell was set up on Jan. 23 at 2:30 P.M. The averages do not include the first four sets of readings.

In these tables the same arrangement of the data has been followed as in the previous article. In order that a comparison of the values recorded in the separate tables may readily be made, the average values in each table together with the transference numbers calculated therefrom have been summarized in Table II.

The headings of Cols. 2, 3, 4, and 5 have the same significance as in the previous article. Cols. 6, 7, 8, and 9 contain the transference numbers calculated from the values in Cols. 2, 3, 4, and 5, as indicated in the headings. Col. 10 contains the sum of the  $N_a$  and  $N_c$  values of Cols. 7 and 9 and should always be equal to unity. The deviation from unity is an indication of the small error of the potentials used in their calculation. The accuracy with which the potentials of  $E_H$  and  $S_{SO_4}$  can be duplicated in the presence of gelatin, is shown by the closeness with which the averages for any two tables of the same concentration agree. From a comparison with similar values in the tables of the previous article, it is plainly evident that when gelatin is present the agreement is less satisfactory than when it is not. This lack of agreement becomes greater the higher the concentration of gelatin. Table III is a summary of the averages of the potentials and transference numbers contained in Table II.

A consideration of the values recorded for  $N_a$  shows that they increase with increase in concentration of gelatin. The relation between the transference number of the anion and concentration of gelatin is shown by the curve in Fig. 2. In this curve the transference numbers are plotted as

Fig. 2.— $N_a$ -gelatin curve.

ordinates and the concentrations of gelatin as abscissas. The change in transference number with increase in gelatin is rapid at low gelatin concentrations, is gradual between 3 and 5%, and above this is not appreciable. If this represents an actual increase in the migration velocity of the anion, then there must be a corresponding decrease in the boundary potential ( $E_B$ ). The values in the columns headed  $E_B$  and  $N_a$  indicate such changes. Since the boundary potential is opposed to the electrode potentials in the case of the hydrogen concentration cell ( $E_H$ ) and is added to the electrode potentials in the case of the sulfate concentration cell ( $E_{SO_4}$ ) a decrease in  $E_B$  would result in an increase in the value of  $E_H$  and a decrease in  $E_{SO_4}$ . That such changes do take place is indicated by the values in the columns headed  $E_H$  and  $E_{SO_4}$ .

It has been shown that the boundary potential depends on the transference numbers of the ions and the ratio of their concentrations in the two solutions. Therefore a change in  $E_B$  would result from a change in concentration or a change in transference number.

The value of  $E_B$  would be reduced by making the concentration of the solutions more nearly equal. When exactly equal  $E_B$  would be zero, and when the concentration of the 0.1  $M$  solution became less than that of the 0.01  $M$ , the direction would be reversed.

To determine whether or not concentration changes are produced by the gelatin, concentration cells of the type  $\text{Pt}_H | 0.1 \text{ } M \text{ } H_2SO_4 | \text{KCl} | 0.1 \text{ } M \text{ } H_2SO_4 + \text{gel.} | \text{Pt}_H$  and  $\text{Pt}_H | 0.01 \text{ } M \text{ } H_2SO_4 | \text{KCl} | 0.01 \text{ } M \text{ } H_2SO_4 + \text{gel.} | \text{Pt}_H$  were used. The data from these measurements are summarized in Table IV.

TABLE IV.

% Gel.	0.1 $M$ .		0.01 $M$ .	
	$C_1$	$E_x$	$C_2$	$E_z$

3	0.05542	0.00181	0.000430.	0.08609
4	0.05356	0.00268	0.000144	0.11418

It was impossible to work with concentrations of gelatin above 4% because of the excessive foaming of the solutions.

The first column contains the percentage of gelatin in the acid in one-half of the cell. The columns  $E_x$  and  $E_z$  contain the measured potentials of the cells  $E_x$  and  $E_z$  when 0.1  $M$  and 0.01  $M$  solutions are used. In columns  $C_1$  and  $C_2$  are the hydrogen-ion concentrations in 0.1  $M$  and 0.01  $M$  solutions with gelatin, calculated by the use of the formula for concentration cells in which boundary potential has been eliminated. The results in columns  $C_1$  and  $C_2$  show that gelatin produces a relatively small decrease in the hydrogen-ion concentration of the 0.1  $M$  solution, and a much greater relative decrease in the 0.01  $M$  solution. The hydrogen-ion concentration of the 0.1  $M$  solution is always greater than that of the 0.01  $M$ ; therefore the reversal of the boundary potential ( $E_B$ ) as shown in Table II cannot result from the concentration changes produced by the gelatin. Since  $E_B$  can be decreased or reversed only by a change in concentration or transference number, the observed change must be due to a change in the transference number.

Since it has been shown above that the gelatin produces changes in the hydrogen-ion concentration, new potentials are developed at the boundaries between the solutions in the wicks and the gelatin solution in the reservoirs. The locations and directions of the boundary potentials,  $E_B$ ,  $E_x$ , and  $E_z$  together with  $E_H$  and  $E_{SO_4}$  are represented diagrammatically in Fig. 3. The location of the boundary potentials is shown also by the same letters in Fig. 1 of the previous article.  $E_B$  represents the potential within the siphon, that is, the potential which has been considered thus far.  $E_x$  and  $E_z$  represent the potentials at the contact of the solutions in the reservoirs.  $E_H$  and  $E_{SO_4}$  are the measured potentials and are the

algebraic sums of the potentials at the electrodes and the boundary potentials  $E_x$ ,  $E_B$ , and  $E_z$ .

The potentials  $E_x$ ,  $E_B$ , and  $E_z$  which result from the presence of the gelatin can be calculated from the data in Table IV by the use of the usual formula for boundary potential. These calculations were made and the results are included in Table V. The potentials at  $E_x$  and  $E_z$  are oppositely directed and the resultant potential is therefore their difference. These differences are recorded in the column headed  $E_z - E_x$ . The total potential at  $E_B$  is opposed to the resultant potentials  $E_z - E_x$  and may be considered as the sum of the original boundary potential  $E_B$  (0.02906) and the potential resulting from the changes in concentration produced by the gelatin. Therefore the differences between the total potentials  $E'_B$  and the original potential  $E_B$  (0.02906) is that due to the changes in concentration produced by the gelatin. The values of these differences are recorded in the column headed  $E'_B - 0.02906$ . As the values in the column headed  $E'_B - 0.02906$  are practically identical with those in  $E_z - E_x$  and oppositely directed, their combined effect must be zero. This shows that the potentials  $E_x$  and  $E_z$  at the contacts between the solutions in the wicks and the gelatin solutions in the reservoirs are entirely compensated by the potential ( $E'_B - 0.02906$ ) simultaneously developed at the boundary  $E_B$ . Therefore any boundary potential produced by the introduction of gelatin cannot result from changes in concentration. The experimental data, however, show that the boundary potential  $E_B$  is changed by the addition of gelatin. Since this cannot be due to concentration changes it must result from a change in the transference numbers of the hydrogen and sulfate ions or from an actual change in the kind of ions present. This may be effected in several ways; (1) by the removal of either ion as the result of its being selectively adsorbed by the gelatin; (2) by a change in the velocity of either ion; (3) by chemical reaction with the gelatin resulting in the formation of new ions.

Since the conductivity of a solution is affected by any change in the number and the mobility of its ions, it was thought that conductivity measurements would furnish information as to the nature of the influence of the gelatin. Measurements were made of the conductivity of 0.1 *M* and 0.01 *M* sulfuric acid solutions which contained different concentrations of gelatin. The concentration of gelatin was varied from 0 to 20%. As it was necessary to apply a correction for the conductivity of the gelatin in conductivity water, a series of measurements was made with gelatin solutions over this same range of concentration. The corrected conductivity values are recorded in Table VI.

The effect of the gelatin on the conductivity of the 0.1 *M* and 0.01 *M* sulfuric acid solutions is also shown by the curves in Figs. 4 and 5. The conductivities are plotted as ordinates and the concentrations of gelatin as abscissas. These curves show that the gelatin produces a greater relative change in the conductivity of the 0.01 *M* sulfuric acid solution than in the conductivity of the 0.1 *M* solution. It should be recalled that in the concentration-cell measurements, recorded in Table IV, the gelatin produced a much greater relative change in the hydrogen-ion concentration of the 0.01 *M* solution than in the 0.1 *M*. In fact, by the addition of about 3 to 4% of gelatin, the concentration of the 0.01 *M* solution was reduced practically to zero. From Fig. 5 it is readily seen that by the addition of about 3% of gelatin the conductivity has been reduced almost to zero. This indicates that not only is the hydrogen-ion concentration reduced by the addition of gelatin but that sulfuric acid is removed as a whole.

Several calculations were made involving the conductivity data and potential data in an effort to determine whether the gelatin produced an actual change in the mobility of the ions, but it was impossible to conclude from these calculations whether the effects obtained were due to concentration changes alone or to concentration changes together with changes in mobility or the presence of new ions.

Two explanations have been offered to account for the action of gelatin, one of which assumes that the ions of the acid are "absorbed" by the gelatin, and the other that a highly dissociable chemical compound is formed.

Supporters of the first theory are H. G. Bennett<sup>4</sup> and A. Mutscheller;<sup>2</sup> and favoring the second theory are H. R. Procter,<sup>5</sup> H. R. Procter and J. A. Wilson,<sup>6</sup> J. Loeb,<sup>7</sup> and W. O. Fenn.<sup>8</sup>

It has been shown in this investigation that some of the properties of sulfuric acid are altered by the presence of gelatin. A summary of the data obtained in the work on its influence on the transference number of the anion of sulfuric acid is contained in Table III. It may be observed that the boundary potential ( $E_B$ ) is reduced from  $+0.02906$  to  $-0.00006$ . Corresponding to this decrease in boundary potential, there is an increase in the

Fig. 4.—Conductivity-gelatin curve for 0.1 M  $H_2SO_4$ .

Fig. 5.—Conductivity-gelatin curve for 0.01 M  $H_2SO_4$ .

potential of the hydrogen concentration cell ( $E_H$ ) from 0.01136 to 0.04155 and a decrease in the potential of the sulfate concentration cell ( $E_{SO_4}$ ) from 0.04918 to 0.02068. There is an apparent increase in the transference number of the anion from 0.187 to 0.685. Any factor which would increase the numerical value of  $E_H$  and decrease  $E_{SO_4}$  would give the observed effect of a decrease in the boundary potential and an in-

crease in the transference number of the anion. This factor was at first believed to be the result of changes in concentration which are recorded in Table IV, due to the presence of the gelatin. A careful consideration of the boundary potentials  $E_x$ ,  $E_B$ , and  $E_z$  which result from these changes in concentration leads to the conclusion that they should neutralize each other. The data in Table VI show this to be the fact. Therefore this effect was not due to the concentration changes brought about by the introduction of the gelatin. This led to the conclusion that the observed changes in the potentials of the concentration cells resulted from a change in the boundary potentials. This decrease in the boundary potential could be produced by any one of three factors. An actual change in the transference numbers; a decrease in the concentration of the 0.1 *M* solution such that it was less than the 0.01 *M* solution; or by a change in the kind of ions present. Since the second of these factors is eliminated by the data recorded in Table IV, which shows that such concentration changes are impossible, it appears that the decrease in boundary potential must be due only to the other factors.

As there is a possibility that a chemical compound which ionizes is formed, the facts are considered also from this point of view. If such is the case there should be a fairly close relation between the amount of gelatin added and the amount of acid removed. This would explain the decrease in hydrogen-ion concentration and decrease in conductivity observed. If such a reaction occurs new compounds are formed and some of the hydrogen ions are replaced by complex gelatin ions which results in the increase in the transference number of the anion as observed. No data were obtained from which the exact amount of sulfuric acid removed by a definite weight of gelatin could be determined.

From the curve for the conductivity of the 0.1 *M* sulfuric acid solution, Fig. 4, it appears that the conductivity of the solution is reduced a definite amount for each additional per cent. of gelatin. The addition of the first per cent. of gelatin in the 0.01 *M* solution also produces about the same reduction in conductivity. This indicates that a definite quantity of gelatin removes a definite amount of sulfuric acid from the solutions. If the compound formed dissociates, and some evidence has been obtained from other sources that it does, then the conductivity curves will tend to flatten at the higher concentrations of gelatin. Loeb<sup>7</sup> has been led to believe that in acid solutions gelatin reacts to form gelatin salts of the acid and in the case of sulfuric acid he states that the gelatin sulfate formed has the composition represented by the formula  $\text{gel}_4(\text{SO}_4)_2$ . The dissociation of such a salt would result in the formation of a slowly moving complex colloidal gelatin cation and a sulfate anion. The transference number of the anion of such a compound would be greater than that of the cation. This conforms to the observed facts. Furthermore, such a compound

would show some conductivity, so that for the higher concentrations of gelatin the decrease in conductivity would no longer be proportional to the gelatin added. This is borne out by the flattening of the conductivity curves at the higher concentrations of gelatin. It should be pointed out that the sharp bend in the conductivity curve of the 0.01 *M* solution, Fig. 5, occurs at about the same concentration as a similar bend in the gelatin transference-number curve, Fig. 2; furthermore it is shown from the gelatin concentration cells, Table IV, that the sulfuric acid in 0.01 *M* solution is practically all removed at this same concentration of gelatin.

These facts indicate that sulfuric acid as such is removed by the addition of gelatin to the solution. Accordingly the apparent change in transference numbers is due not to an actual change in the velocity of the  $H^+$  and  $SO_4^{--}$  ions, but to the presence of new ions in the solution resulting from the dissociation of the gelatin—sulfate compound.

It is the opinion of the authors that the action of gelatin and sulfuric acid results in the formation of a single dissociable product in which the  $H^+$  ion of the acid loses its identity. It is further believed that in the presence of a base a similar product would result in which the identity of the  $OH^-$  ion would be lost and that in the presence of a neutral salt solution no similar action would result. At the present time investigations are being conducted by the authors to confirm this hypothesis.

### Summary.

1. The effective concentration of 0.1 *M* and 0.01 *M* sulfuric acid solutions has been found to be reduced by the addition of gelatin.
2. The transference numbers of 0.1 *M* and 0.01 *M* sulfuric acid solutions have been found to be altered by the presence of gelatin.
3. The conductivities of sulfuric acid solutions have been found to be reduced by the presence of gelatin.
4. An hypothesis has been offered to account for the action of gelatin in the presence of electrolytes

## SOLUBILITY VII. SOLUBILITY RELATIONS OF RHOMBIC SULFUR.

BY JOEL H. HILDEBRAND AND CLARENCE A. JENKS.

Received June 28, 1921.

The solubility relations of sulfur are of considerable interest in the light of the theory of solubility set forth in the previous papers of this series<sup>1</sup> because liquid sulfur,  $S_\lambda$ , has a rather high internal pressure compared with most liquids and the solubilities of rhombic sulfur should therefore serve well to illustrate the decreasing solubility to be expected as the internal pressure of the solvent decreases.

The solubilities of sulfur have been the subject of frequent investigation. We have data by Étard<sup>2</sup> for hexane, benzene, ethylene bromide and carbon bisulfide; by Gerardin<sup>3</sup> for stannic chloride in the neighborhood of the melting point of sulfur; by Aten<sup>4</sup> for sulfur monochloride; by Smith and Carson<sup>5</sup> for iodine; by Cossa<sup>6</sup> for chloroform, ethyl ether, benzene, carbon disulfide and toluene; by Retgers<sup>7</sup> for methylene iodide; by Brönsted<sup>8</sup> for benzene, iodobenzene and chloroform; by Hoffman<sup>9</sup> for carbon tetrachloride, dichloro-ethylene, ethylene chloride, pentachloro-ethane, perchloro-ethylene, trichloro-ethylene and tetrachloro-ethane. There are other data for more or less polar solvents, including phenol,<sup>10</sup> naphthol<sup>10</sup> and alcohols<sup>11,3</sup> but the only polar solvent we shall consider is ammonia, for which we have data by Ruff and Hecht.<sup>12</sup>

Some of the data referred to are obviously not very accurate, and many of the determinations were made only at one temperature. Accordingly it has been desirable to check certain portions and to supplement others. We have measured solubilities in carbon tetrachloride, benzene, toluene, *m*-xylene, heptane and ethylene chloride.

The sulfur was purified by sublimation. The ethylene chloride was purified by distillation. The carbon tetrachloride, heptane and benzene used were from the stocks

purified for the recent investigation by us of the solubilities of iodine. The toluene was purified by the method used by Richards and Coombs.<sup>13</sup> The *m*-xylene was purified by a modification of the method described by Levinstein.<sup>14</sup> The *o*- and *p*-xylenes occurring in ordinary xylene were oxidized by treatment with 40% nitric acid until about a third of the original xylene had been destroyed. The *o*- and *p*-toluic acids are formed more readily than the *meta* variety. The xylene remaining was washed with sodium hydroxide and water to remove the acids. Nitro bodies were also formed in this process, which were removed by long reduction, first by hydrochloric acid and tin, then by sodium hydroxide and zinc dust. The liquid was then treated with conc. hydrochloric acid and distilled with steam. The distillate was fractionated thrice, giving a constant fraction boiling at 139.0°.

<sup>13</sup> Richards and Coombs, *THIS JOURNAL*, **37**, 1668 (1915).<sup>14</sup> Levinstein, *Ber.*, **17**, 444 (1884).

The solubility determinations were made by the aid of the vessel described in the previous investigation, except that the solutions were blown into "ducks" similar to those described in "Physiko-Chemische Messungen," by Ostwald-Luther. In the earlier experiments these "ducks," after weighing, were placed upon an electrically heated plate where the solvent was evaporated. The weight of the sulfur remained constant, upon further heating after the evaporation of the solvent. In the later experiments the solvent was evaporated without heating by blowing a current of air through the vessel. Before weighing, the sulfur was heated to fusion.

Table I contains the results of the determinations from 0° to 54°, expressed in weight percentages, grams of sulfur per 100 g. of solution, and expressed also in mol percentages, mols of sulfur, S<sub>8</sub>, per 100 mols of solution. The figures in the last row for each solvent are the average values. Further observations were made at higher temperatures with benzene, toluene and *m*-xylene, respectively, by making up solutions of known composition and noting the temperature at which a minute residual crystal neither increased or diminished in size when observed through a low-power microscope. These results are given in Table II.

TABLE II.

	Benzene.	Toluene.	<i>m</i> -Xylene.

Mol. per cent. ....	4.36	4.52	4.53

The results of our own experiments together with most of those of other observers, previously cited,<sup>15</sup> are plotted in Fig. 1, using as ordinate the logarithm of the solubility expressed in terms of mol-fraction, and as abscissa, the reciprocal of the absolute temperature. The significance and value of this method of plotting solubility has been explained in the fifth paper of this series.<sup>16</sup>

### Discussion.

The curves in Fig. 1 show very strikingly the deviations of these solutions from the solubility that would be expected in a solvent with which sulfur obeyed Raoult's law. The line corresponding to the ideal solubility is calculated from the melting point and the heat of fusion of rhombic sulfur, using data given in a paper by Lewis and Randall<sup>17</sup> and corresponds to an ideal solubility for S<sub>8</sub> of mol-fraction 0.282 at 25°. The heat of solution of sulfur in such a solvent is the same as its heat of fusion, or, in other words, such a solvent would mix with molten sulfur with no heat effect.

The position of sulfur in the table of internal pressures given in our third paper may be determined by the aid of the following data. Toepler<sup>18</sup> has given the specific volume of supercooled sulfur at 20° as 0.951 times

<sup>15</sup> The data by Cossa are evidently of inferior accuracy and have been omitted.

<sup>16</sup> See also Braham, *THIS JOURNAL*, 41, 1715 (1919).

<sup>17</sup> Lewis and Randall, *ibid.*, 36, 2468 (1914).

<sup>18</sup> Toepler, *Wied. Ann.*, 47, 169 (1892)

the specific volume at  $120^\circ$ , which according to Pisati<sup>19</sup> is 0.5541. From these figures we calculate the molecular volume of liquid sulfur  $S_8$ , at  $20^\circ$  as 135 cc.

The surface tension of sulfur at  $20^\circ$  is 60.0.<sup>20</sup> This gives  $\gamma/V^{1/3} = 11.7$ , which would place sulfur close to iodine in internal pressure.

From the vapor pressure measurements of Ruff and Graf<sup>21</sup> we calculate the heat of vaporization of sulfur at low temperatures to be 19,100 cal.

Fig. 1.—Solubilities of rhombic sulfur.

per mol. From this we get  $L_v/V = 137$ , which, again, would place sulfur just above iodine in internal pressure. Unfortunately, data do not exist for the calculation of the internal pressure by the more accurate method of our sixth paper.

We should thus expect that sulfur would obey Raoult's law rather closely with iodine, and that its solubility would decrease progressively as we

<sup>19</sup> Pisati, *Gazz. chim. ital.*, 4, 29 (1874).

<sup>20</sup> Cf. Harkins, Davis and Clark, *THIS JOURNAL*, 39, 541 (1917).

<sup>21</sup> Ruff and Graf, *Ber.*, 40, 4199 (1907).

change to solvents of lower internal pressure. By comparing the curves in the figure with the table of internal pressures given in our third paper the order will be seen to correspond, on the whole, very well.

A minor discrepancy exists in the cases of toluene and xylene. These have internal pressures smaller than that of benzene so that lower solvent power for sulfur would be expected; in the case of xylene about the same as that of carbon tetrachloride. The reason for this discrepancy will be discussed in a future theoretical communication. We will merely note that the expected order is attained at higher temperatures with liquid sulfur. According to observations by Alexejeff<sup>22</sup> the critical temperature of mixing of benzene and sulfur is 163°, whereas with toluene it is 180°. Of course, at these temperatures considerable  $S_\mu$  is present so that they cannot be regarded as true measures of the solubility of  $S\lambda$ .

Ethylene chloride, shows an abnormally low solvent power. Its internal pressure is greater than that of benzene, but its solvent power for sulfur is considerably less than that of carbon tetrachloride. This is undoubtedly due to its polar character, as shown by its dielectric constant of 10.4. The dielectric constant of liquid sulfur is only 3.4. As the polar character diminishes with rising temperature we find the solvent power of ethylene chloride increasing somewhat more rapidly with temperature than does that of a normal substance such as carbon tetrachloride. Ethylene bromide, with a smaller dielectric constant, 4.9, shows a solvent power nearly as great as its internal pressure would lead one to expect. Tetrachloroethylene,  $C_2Cl_4$ , with a dielectric constant of only 2.46 has about the solvent power indicated by its internal pressure. The other solvents investigated by Hoffman have not been included in the plot, partly because of lack of space, partly because of lack of knowledge concerning their physical constants. In general, however, we may state that their solvent powers accord well with the theory.

The figures of Aten for sulfur monochloride show, when plotted, considerable irregularity. Those for hexane by Étard, not included in the plot, are very close to our own for heptane, but a smaller slope than that of the other curves of the family indicates some inaccuracy. The small solubility of sulfur in hexane makes accurate determinations difficult. Étard's figures for benzene also do not fall very closely upon the curve.

Methylene iodide, which was not given in the table of internal pressures, has a value for  $L/V$  of 136, which places it below sulfur monochloride and accords exactly with its solvent power for sulfur.

The curve for ammonia, which is included as an interesting illustration of a solvent power to be attributed to solvation, falls off at higher temperatures, quite unlike the other cases given. The prediction of such

<sup>22</sup> Alexejeff, *Wied. Ann.*, 28, 305 (1886).

behavior is outside the scope of the theory and is part of the great unsolved problem of chemistry, the prediction of chemical combination.

The deviations from Raoult's law for most of the substances here considered is sufficient to cause the existence of two liquid phases above the melting point of sulfur. Therefore, the curves below that of ethylene bromide do not converge to the melting point of sulfur but would be continued to the left as the solubility curves for liquid sulfur, ending at the critical temperatures of mixing. The data for this region are fragmentary and conflicting, so that we have not attempted to include them in this paper.

We may note the possibility offered by such a family of curves of constructing a solubility curve from a single point, as we have done in the figure for methylene iodide, iodobenzene and tetrachloro-ethylene. The solubility of sulfur in these solvents at any desired temperature can be read from such a curve. Such a procedure would not, of course, be valid in the case of a very polar solvent, or of one, like ammonia, which forms a solvate with the sulfur.

In conclusion we would point out the enormous deviations from Raoult's law which most of the solubilities of sulfur represent, the extreme case being with heptane, where the solubility at  $25^{\circ}$  is 0.00141, expressed as mol. fraction, while the solubility according to Raoult's law is 0.282. It is also evident that there is no justification in attempting to account for this variation by the assumption of any abnormal molecular weight for either substance. What is required is a substitute for Raoult's law for defining the ideal solution. The study of this subject is now in progress.

### Summary.

Solubilities of rhombic sulfur at various temperatures have been measured in the following solvents: heptane, ethylene chloride, carbon tetrachloride, benzene, toluene, and *m*-xylene.

These data, together with many obtained by other observers in these and other solvents, have been plotted by the method previously used by us for evaluating solubility data.

It is shown that, with the exception of certain minor discrepancies, the solubilities of sulfur accord well with the internal pressure relations of the substances involved.

## POLYMORPHIC TRANSFORMATIONS OF ANTIMONY TRISULFIDE.

BY SAMUEL WILSON, WITH C. R. MCCROSKY.

Received June 30, 1921.

Between 1878 and 1890 several researches<sup>1,2</sup> on the transformation of the red anhydrous and the orange hydrated forms of antimony trisulfide into the black variety were performed. Those of Ditte<sup>3</sup> and Lang<sup>4</sup> were most significant, but neither investigator worked under rigorously controlled conditions. Lang used aqueous hydrochloric acid at room temperature and found that the time required for transformation of the red form to the black varied inversely with the concentration of the acid employed, ranging from 8 days for a 22% to 150 days for a 1% solution. Ditte worked with the orange-red dihydrate, using excess of acid and high temperatures.

A more quantitative study of this transformation appeared to us desirable. Accordingly the red sulfide was prepared by precipitation with washed hydrogen sulfide from a dil. tartar emetic solution acidified with tartaric acid. The precipitate was washed in succession with water, potassium carbonate solution, water, tartaric acid solution, water, alcohol, carbon disulfide and ether, then dried at 110°. The brick-red amorphous sulfide thus obtained was powdered and passed through a 40-mesh screen,

The first series of experiments was carried on with 2g. samples of the sulfide in small flasks. Five-cc. portions of the reagent were added, the flask stoppered and examined at regular intervals to note whether a change to the black form had occurred. The temperature ranged from 18° to 22°. As reagents hydrochloric acid of 1 *N*, 7 *N*, and 12 *N* concentrations, 7 *N* phosphoric acid; 7 *N* sulfuric acid; glacial and 1 *N* acetic acid, and an ether solution saturated with dry hydrogen chloride were employed. Of these, only the hydrochloric acid solutions in water gave any appreciable transformation, even after the lapse of two months. The time required for these was much less than for those found by Lang. For 12 *N*, 7 *N* and 1 *N* hydrochloric acid, the time required for transformation was 0.5 day, 1 day and 10.5 days, respectively.

Time measurements in all cases were made to the point of final transformation, that is, until no more red particles could be seen. At lower temperatures the transformation is gradual, the finer particles changing first, but it speeds up towards the end, and at higher temperatures is so rapid that the eye can scarcely measure the time interval between incipient and final transformation.

<sup>1</sup> Clermont and Frommel, *Compt. rend.*, 86, 87 (1878).

<sup>2</sup> Scheuerman, *Ann.*, 249, 339 (1888).

<sup>3</sup> Ditte, *Compt. rend.*, 102, 212 (1886).

<sup>4</sup> Lang, *Ber.*, 18, 2716 (1885).

The difference between the above results and those of Lang may be due in part to the greater fineness of our particles, but it is more probably explained by the fact that Lang permitted the evolved hydrogen sulfide to escape, thus constantly displacing the equilibrium, whereas in these experiments all the flasks were carefully stoppered.

The action is due, apparently, to a solution of the red sulfide in the acid, followed by a reprecipitation of the less soluble black modification. These black crystals under the microscope showed the characteristic orthorhombic faces of the mineral stibnite.

Further experiments were made to determine the effect of temperature on the velocity of transformation. A 20% hydrochloric acid solution was used, with the same proportions of acid and red sulfide as before. The experiments were carried out in a thermostat at a series of temperatures up to 75° with a maximum variation of 0.5°; 25cm. test-tubes were used instead of flasks.

Temperature. °C.	Time required.	
	Hrs.	Min.
26.5	44	..
30	29	..
35	16	..
40	9	..
68.5	..	62
75	..	32

The very rapid increase of speed of transformation with rise of temperature is noteworthy.

Under similar conditions, a 20% solution of hydrobromic acid gave no visible blackening, even after 20 hours at 75°.

## THE REDUCTION OF COPPER OXIDE BY HYDROGEN.

BY ROBERT N. PEASE AND HUGH STOTT TAYLOR.

Received July 5, 1921.

This investigation of the reduction of copper oxide by hydrogen was undertaken in the hope that the results might throw some light on the mechanism of the catalytic combination of hydrogen and oxygen in the presence of metallic copper, in a study of which we have been engaged.<sup>1</sup> Since copper oxide may be reduced by hydrogen and the resulting copper may be re-oxidized without difficulty at temperatures at which the metal is catalytically active, it would appear that, in all probability, the catalytic reaction proceeded as a result of the alternate oxidation and reduction of the copper. Certain of our results were apparently inconsistent

<sup>1</sup> The results of this investigation will be published shortly.

with this interpretation, however, and it was thought that a study of the reduction reaction by itself might be of assistance in clearing up the discrepancy. As an examination of the literature revealed that this reaction possessed several peculiarities of its own, the investigation seemed the more worth while.

A rather extensive investigation of the reduction of copper oxide by hydrogen has been carried out by Wright, Luff and Rennie.<sup>2</sup> Hydrogen was passed at a constant rate through a U-tube containing copper oxide held at various fixed temperatures by means of vapor baths and the rate of reduction determined by weighing the U-tube from time to time. It was found that the reduction was preceded by an "incubation" period, the length of which was greater the lower the temperature. Following the incubation period, (during which there was no perceptible reaction) reduction set in at a steadily increasing rate (induction period) till a maximum was reached, after which the rate decreased gradually to zero as the reaction approached completion. Experiments were carried out at several temperatures between 130° and 257°. In other experiments, copper oxide was spread on the bottom of a small flask heated in a vapor bath, and a current of hydrogen was passed through the flask. The authors' description of the progress of the reaction is instructive. "The reduction commenced visibly by the formation of a red speck amongst the little mass of copper oxide at the lowest part of the bulb; this quickly spread, becoming rapidly larger and larger until practically the whole mass became a reddish metallic powder, the progress of the reaction reminding one of the slow deflagration of a quantity of touch paper, *the reducing action being apparently propagated from particle to particle through the mass.*" This occurred, be it remembered, in the presence of an excess of hydrogen.

It is evident from these results that the reaction is auto-catalytic, copper being the auto-catalyst, in all probability. The reaction starts only after some time—at least as evidenced by the change in weight of the tube containing the oxide<sup>3</sup>—with the formation of one or more visible nuclei of copper. From these as centers, the zone of reaction, that is, the copper-copper oxide interface, spreads out and as its area increases the rate of water formation increases.

If the induction period is due to the initial absence of metallic copper, it should be possible to shorten it or cause it to disappear altogether by adding already reduced copper to the oxide about to be reduced. It seemed

<sup>2</sup> Wright, Luff and Rennie, *J. Chem. Soc.*, 33, 1 (1878); 35, 475 (1879).

<sup>3</sup> That the tube does not lose weight during the first part of the run does not necessarily prove that reaction is not taking place at an exceedingly slow though steadily increasing rate. Various sources of error, particularly the retention of the water formed through adsorption, might obliterate any effect of the expected magnitude. The reproducibility of the results would indicate that the reaction does not start merely by accident.

worth while to try to confirm this experimentally. Further, since water as well as copper is a product of the reaction, it was decided to determine the effect of adding more water to the system as moisture in the hydrogen.

### Experimental.

A sketch of our apparatus is shown in Figure 1.

Electrolytic hydrogen from the tank A was passed through heated palladized asbestos in the tube B to convert the small percentage of oxygen present in the hydrogen to water, through the flow-meter C, the phosphorus pentoxide drying-tube D and then through the electrically heated furnace E, which contained the copper oxide. The

Fig. 1.—Apparatus.

furnace consisted of two concentric glass tubes, the inner one of which contained the oxide. The outer tube was wound with Nichrome wire and was covered with magnesia pipe covering. Rates of reduction were measured by determining the rates of water formation. This was accomplished by passing the effluent hydrogen through a U-tube containing calcium chloride (G) for definite time intervals and noting the increase in weight due to water absorbed. The rate of reduction is expressed throughout in terms of milligrams of water absorbed by the calcium chloride tube in 5 minutes' passage of the effluent hydrogen. The rate of flow of the hydrogen was maintained constant at 50 cc. per minute. Samples of 5 cc. apparent volume of copper oxide, weighing within a few tenths of 10 g. were always employed. As the containing tube was 2.5 sq. cm. in cross section, this gave a layer of copper oxide about 2 cm. deep. An imported copper oxide in granules intended for organic analysis, "hirsekorngrosse," (about 10- to 20-mesh) was used.

For the purpose of checking the results of Wright, Luff and Rennie as to the character of the reaction and in order that we might have standards with which to compare our other experiments, we have obtained reduction curves at 150° and 200°. These are presented in Fig. 2. It will be seen that these possess the characteristics reported by the above authors. There is the incubation period (practically non-existent at 200°) followed by the period of increasing rate of reduction to a maximum and finally the period of decreasing rate. At 200° the maximum rate of reduction corresponded to the formation of 130 mg. of water in 5 minutes. If all the hydrogen had been consumed the rate of formation of water would have been 184 mg. in 5 minutes. Although the design of the furnace

prevented direct visual observations of the progress of the reaction, its characteristics were made clear by an examination of samples in various stages of reduction. It was found that reduction *practically never started at the top*, where the preheated hydrogen first met the charge, but usually at some point near the middle of the charge along the side of the tube. From these points as nuclei, the reaction zone appeared to spread over the whole mass.

Fig. 2.—Reduction of copper oxide by hydrogen. Curve I, reduction at 150°. Curve II, reduction at 200°.

**Effect of Copper.**—In one experiment, a layer of previously reduced granules was placed on top of the oxide, which was then treated with hydrogen at 150°. The result is shown graphically by Curve II, Fig. 3. Curve I represents the standard reduction with pure copper oxide and hydrogen. It is the initial portion of Curve I, Fig. 2 on a larger scale. By comparing the curves it may be seen that the layer of copper considerably hastened the setting-in of the reaction and nearly eliminated the incubation period. An examination of the sample after reduction had proceeded for several hours showed that the reaction had begun at the top of the charge in contact with the copper and had proceeded downward in wave front roughly normal to the direction of hydrogen flow. Since ordinarily reduction begins within the charge rather than at its surface, the top being reduced toward the end instead of at the beginning of the run, it would appear that the layer of copper had rendered the oxide in contact with it the more reactive, substantiating the assumption that the reaction is autocatalytic and takes place mainly and most easily at a copper-copper

oxide interface. The reaction did not subsequently reach as high a rate as did the standard, as the curve shows. Ordinarily, the reaction starting at some point within the charge, the area of the interface will be at least twice the cross-sectional area of the tube since there will be an interface above and another below the reduced portion. In the case described above the area of the interface was only that of the cross-section of the tube, and, as it is thought that the rate of water formation is proportional to the interface area, the reaction would not be expected to reach as high rates as it did in the standard run, since the interface area is only about half as great.

Fig. 3.—Reduction at 150°. Curve I, Normal reduction. Curve II, in presence of metallic copper. Curve III, effect of water vapor; 5 mg. per 5-minute interval. Curve IV, effect of preliminary treatment with dry air. Curve V, effect of oxygen equivalent to 10 mg. of water per 5-minute interval. Curve VI, effect of oxygen equivalent to 5 mg. of water per 5-minute interval.

**Effect of Water Vapor.**—Water vapor was added to the hydrogen in the following manner.—An electrolytic gas generator F (Fig. 1), consisting of a wide mouth test-tube containing caustic soda solution in which were immersed 2 spiral nickel wire electrodes, was connected to the hydrogen line. By connecting the electrodes of the generator in series with a variable resistance and a milliammeter, electrolytic gas could be generated at a definite rate into the hydrogen stream, and, by causing the latter subsequently to pass over heated palladized asbestos, the electrolytic gas could be reconverted into water vapor. In these experiments, the cell was

run at such a rate that 5 mg. of water was decomposed (and subsequently synthesized over the palladized asbestos) in 5 minutes. The milliammeter setting was 0.180 amperes. In the 250 cc. of hydrogen which was passed in 5 minutes, this is equivalent to about 2.7% water vapor by volume. This amounts practically to saturation at room temperature. The result of passing this saturated hydrogen over copper oxide at 150° is shown by Curve III, Fig. 3. Not only was reduction prevented during the exposure (reduction would normally have started in 1 to 1½ hours) but in addition did not start for nearly 2 hours after the electrolytic gas was shut off and pure dry hydrogen alone passed over the oxide.

From these results it is clear that water vapor strongly inhibits the initial reaction between hydrogen and copper oxide—that is, it effectively prevents, at this temperature, the formation of copper nuclei. Since it is a product of the reaction it clearly has no such powerful action on the subsequent reaction at the interface. This was confirmed by adding water vapor to the hydrogen again some time after reaction had started. Referring again to Curve III, Fig. 3, it is seen that under these conditions, after an apparent temporary set-back, the reaction proceeded in much the normal fashion.

That the system experienced an exceptionally long incubation period even after the water vapor was shut off suggested that possibly adsorbed water was partially responsible for this phenomenon in the ordinary runs, especially since water vapor so strongly inhibits the preliminary reaction. Accordingly, the effect was tried of drawing dry air through the charge at 150° for 3 hours prior to reduction in order to sweep out any moisture. Air dried by means of a calcium chloride tower was aspirated through the sample at the rate of 50 cc. per minute. At the end of 3 hours, the sample was cooled nearly to room temperature, the air then displaced by hydrogen and the temperature again raised to 150°. The reduction proceeded according to Curve IV, Fig. 3. The result was that the incubation period was reduced to about half its normal length but was not completely wiped out. It would appear, therefore, that the presence of adsorbed water is not alone responsible for the incubation period.

According to Wright, Luff and Rennie,<sup>2</sup> when air (probably undried) was drawn over heated copper oxide for 15 minutes and then the hydrogen current substituted, the incubation period was considerably lengthened. We believe this to be due to the fact that moist air was used and the air swept out by hydrogen while the oxide was hot, when a small quantity of water would certainly be formed, the water absorbed from the air and that formed by catalytic combination being sufficient to retard the reaction.

At 200°, the effect of water vapor was to cause a definite though brief incubation period when none was normally noted. (Curve II, Fig. 4. Curve I refers to the normal reduction.) It did not prevent the reaction

starting, as it did at  $150^{\circ}$ , however. After having once started, the reaction proceeded normally, as was to be expected if water vapor does not affect the reaction at the copper-copper oxide interface.

**Effect of Oxygen.**—Results obtained during the experiments on the catalytic combination of hydrogen and oxygen in the presence of copper indicated that the oxygen present inhibited the reduction of the oxide formed simultaneously with the water, for when the oxygen was shut off, the rate of water formation always rose temporarily to a value considerably greater than that when oxygen had been present.

Further evidence that oxygen inhibits the reduction of copper oxide by hydrogen is afforded by some experiments of Bone and Wheeler.<sup>4</sup> Using a method involving circulation of the gases in a closed system, one part of which was a heated tube containing copper oxide, they found that the rate of consumption of hydrogen from a mixture of 2 parts of hydrogen and 1 part of nitrogen was nearly 10 times as great as from electrolytic gas (2 parts of hydrogen and 1 part of oxygen). The experiments were carried out at  $214^{\circ}$ . It can hardly be assumed that the nitrogen accelerated the reaction; rather would it appear that, with electrolytic gas, the oxygen present inhibits the reduction to such an extent that the combined

rates of reduction and hydrogen-oxygen combination are less than the normal rate of reduction in the absence of oxygen.

For the purpose of confirming these indications, the rates of reduction of copper by hydrogen containing oxygen were determined. Oxygen was added to the hydrogen by connecting with the hydrogen line the electrolytic gas generator used in the experiments with water vapor. The oxygen concentrations are expressed in terms of the corresponding weight

Fig. 4.—Reduction at  $200^{\circ}$ . Curve I, normal reduction. Curve II, effect of water vapor: 5 mg. per 5-minute interval. Curve III, effect of oxygen equivalent to 5 mg. per 5-minute interval. Curve IV, effect of oxygen equivalent to 10 mg. per 5-minute interval.

<sup>4</sup> Bone and Wheeler, *Phil. Trans.*, 206A, 1 (1906).

of water in milligrams which could theoretically be formed from the oxygen during a 5-minute passage of the mixture. Thus, "oxygen equivalent to 10 mg. of water per 5-minute interval" means that the quantity of oxygen present in the hydrogen passed through the apparatus in 5 minutes was sufficient to form 10 mg. of water. This is equivalent to 2.5% of oxygen by volume at 25°, the hydrogen being run at the rate of 50 cc. per minute.

As had been anticipated, it was found that the presence of oxygen very seriously interfered with the reduction reaction. In one experiment, hydrogen containing oxygen equivalent to 10 mg. of water per 5-minute interval was passed over copper oxide for 5 hours, during which period no formation of water could be detected. It appears, therefore, that under these conditions the oxide is not appreciably reduced nor does it possess appreciable catalytic activity toward the combination of hydrogen and oxygen. (Curve V, Fig. 3.) Normally, with pure hydrogen, reduction would have become measurable in 1 to 1½ hours. Directly the oxygen was cut off, reduction set in, the maximum rate being much greater than in any other runs. The incubation period was therefore eliminated by this treatment. It will be recalled that similar treatment with water vapor only resulted in postponing the incubation period. After reduction had been allowed to proceed for a short time, oxygen was again turned on. As a result, the rate of reduction was very markedly repressed, dropping from 31 to 5 mg. of water per 5-minute interval, and did not recover until the oxygen was shut off. Subsequent addition of oxygen resulted in a repetition of this effect.

As Curve VI, Fig. 3, shows, oxygen equivalent to 5 mg. of water per 5-minute interval produces similar effects.

At 200°, (Curves III and IV, Fig. 4), the effect of oxygen was to retard the reduction very strongly though the latter was not completely prevented. The quantities of water formed under these conditions are undoubtedly due in part to catalytic combination; nevertheless, it is clear from the curve that at the end of 3 hours, the charge had not been appreciably reduced whereas reduction would normally have been nearly complete at the end of this time.

The effects produced by oxygen are seen to be quite distinct from those produced by water vapor. (It was possible that they might have been due to the formation of the latter.) At 150°, preliminary treatment with hydrogen containing water vapor not only results in no water formation but postpones the incubation period till the water vapor is cut off. After reduction has commenced, however, further addition of water vapor has no marked effect. With oxygen in the hydrogen, on the other hand, the incubation period is eliminated (that is to say, reaction starts directly the oxygen is cut off) although no reduction takes place during the exposure; but addition of oxygen after reduction has started very markedly represses

the reaction. Clearly water vapor is only effective in the initial reaction between hydrogen and copper oxide. This may be attributed to the strong adsorption of water vapor by copper oxide. Comparisons of the quantities of water added to the hydrogen and quantities recovered from the effluent hydrogen during the first few minutes of the exposures to water vapor indicated that quite large quantities of water vapor must have been taken up. Oxygen, on the other hand, probably is effective only in the reaction taking place at the interface. At first sight it would appear that it also inhibits the initial reaction. However, the fact that reduction commenced directly the oxygen was cut off seems to indicate that the formation of copper nuclei had been going on during this period; that is to say, the elimination of the incubation period is taken to indicate that the primary reaction had taken place even in the presence of oxygen. The abnormally rapid rise to an abnormally high maximum after the oxygen had been turned off and reduction once started further indicates the existence at that time of numerous centers of activity. This is consistent with the observations of Dr. A. F. Benton in this laboratory that oxygen is not markedly adsorbed by copper oxide, at these temperatures.

It has been suggested that the retarding effect of oxygen on the reaction at the interface is due to its adsorption by the interface. It is a little difficult to conceive of oxygen remaining long in the adsorbed state at the interface, the seat of activity in the reduction reaction. Granting that oxygen may be so adsorbed, it would seem very probable that it would either immediately be converted to oxide or else react directly with hydrogen to form water (and such a view of the catalytic reaction has its advantages). The reaction to form oxide, if carried far enough, would eventually decrease the area of the interface materially and hence the rate of water formation. Thus, qualitatively, the effect of oxygen would be accounted for. However, the effect of the oxygen is immediate and it is doubtful whether sufficient oxygen is initially present to reduce the interface area by the required amount. This would certainly require all the oxygen present in the gas for a considerable time and yet it is known that even starting with a pure copper surface, the major part of the oxygen goes to form water, although the remainder does combine to form oxide. It is perhaps more satisfactory to assume for the present that oxygen is in fact strongly adsorbed by the interface and protects it from the hydrogen, and although constantly being consumed in the formation of water and oxide, is nevertheless renewed at a sufficiently rapid rate to maintain the protective film.

### Summary.

1. An investigation of the characteristics of the reduction of copper oxide by hydrogen and the effect on the reaction of adding metallic copper

to the oxide and water vapor and oxygen to the hydrogen has been carried out.

2. It has been pointed out that the reaction is auto-catalytic, copper being the auto-catalyst. The reaction thus appears to take place at the copper-copper oxide interface. This is shown by the character of the reduction curve and the fact that addition of metallic copper accelerates the reaction.

3. It has been shown that the presence of water vapor in the hydrogen markedly interferes with the formation of the original copper nuclei from which the reaction zone, that is, the copper-copper oxide interface spreads out; it does not markedly affect the subsequent reaction at the interface, however.

4. The presence of oxygen in the hydrogen strongly inhibits the reaction at the interface but in all probability has no marked effect on the primary reaction, that is, the formation of the original copper nuclei.

## THE HEATS OF SOLUTION AND OF TRANSFORMATION OF THE ACIDO AND AQUO COBALT PENTAMMINES.

BY ARTHUR B. LAMB AND JOHN P. SIMMONS.\*

Received July 11, 1921.

### Introduction.

The spontaneous transformations of a number of the acido cobalt pentammines into their corresponding aquo compounds have been carefully studied.<sup>1</sup> They have been found to go nearly to completion at ordinary temperatures in aqueous solutions and, as regards velocity, to follow the course of a monomolecular reaction. At higher temperatures the reaction becomes more evidently reversible, and it has been shown that an equilibrium is attained which strikingly resembles the dissociation equilibria of strong electrolytes in water.

Particularly because of this wider bearing of the subject we have investigated the heat changes accompanying a number of these transformations in aqueous solution. These heat changes could be calculated from equilibria data at different temperatures, did such exist, but unfortunately there are experimental difficulties in studying these equilibria except within a narrow temperature interval. We have therefore been

\* This paper is largely based on a dissertation of the same title submitted by J. P. Simmons in partial fulfillment of the requirements for the degree of Doctor of Philosophy at New York University, 1912.

<sup>1</sup> Lamb and Marden, *THIS JOURNAL*, 33, 1873 (1911).

obliged to employ a direct method of measurement; direct, at least in the sense that only thermal quantities are measured. A really direct measurement of the heat of reaction would be difficult, not only because the most rapid of these transformations are relatively slow, but also because the ammines are for the most part far too insoluble to furnish solutions of adequate concentration.

The method which we have employed depends upon the use of an aqueous solution of sodium sulfide, which reacts rapidly at room temperatures with both the acido and aquo ammines, and produces the same substances in identical amount, except for the liberation of a molecule of water from the aquo ammine.

The difference then in its heat of reaction with an acido ammine on the one hand and with the corresponding aquo ammine on the other will evidently be equal to the heat of transformation of the acido into the aquo ammine.

The rigor of this method evidently depends on the precise identity of the products formed from the acido and the corresponding aquo ammine. The sulfide of cobalt is the only one of the products affording any possibility of dissimilarity. There was no indication whatever that such a dissimilarity existed, and yet the matter was of such fundamental importance that a careful study of the composition of the sulfide formed from the chloro- and the aquo-pentammine chlorides was made. The two sulfides were prepared under the same conditions as prevailed during an actual calorimetric determination, and were then carefully analyzed for sulfur. The chloro-pentammine for these experiments was an imported preparation which had been proved pure by repeated analyses.

The aquo-pentammine chloride was prepared and purified by Jørgensen's method.<sup>2</sup> The ionizable chlorine in the chloro-pentammine was determined by precipitating with silver nitrate solution at 0°, and rapidly coagulating and filtering off the silver chloride. Two samples weighing about 0.4 g. gave 28.27 and 28.24% of chlorine, while the theoretical percentage is 28.31. The aquo-pentammine chloride was analyzed for total chlorine by warming gently with an excess of silver nitrate solution. Two 0.5g. samples gave 39.56 and 39.52% of chlorine, while the theoretical composition is 39.62% of chlorine. These analyses establish the purity of these salts.

The compositions of the cobalt sulfide precipitates were determined by starting from weighed quantities of the ammines, precipitating with sodium sulfide, washing the precipitate from sodium chloride, ammonia, and the excess of the precipitant, and oxidizing the sulfide to sulfate by an ammoniacal solution of hydrogen peroxide, acidifying, and precipitating the sulfate as barium sulfate. The chief difficulty in this analysis lies in the sensitiveness of the cobalt sulfide to oxidation to sulfate by the oxygen of the air during the process of precipitation and washing. This difficulty was successfully overcome by precipitating, washing, and filtering the sulfide in an atmosphere of hydrogen.

<sup>2</sup> Jørgensen, *Z. anorg. Chem.*, 17, 455 (1898).

The apparatus for this purpose consisted of a Gooch adapter set in a suction flask by means of a tight-fitting rubber stopper. In the top of the adapter was a 3-hole rubber stopper containing a connection to a Kipp generator for hydrogen, a dropping funnel with a stopcock, and an outlet of glass tubing with a stopcock attached. By proper manipulation of the stopcocks air was expelled by hydrogen; sodium sulfide and wash water were admitted, and filtration accelerated. At the bottom of the adapter was an asbestos filter between two perforated porcelain disks.

Weighed samples of the ammines were placed upon the filter and hydrogen gas run through the apparatus for several hours. Fifty cc. of sodium sulfide solution was then introduced and the closed apparatus shaken to bring about complete reaction with the ammine. After standing for some time the solution was filtered off, freshly boiled water introduced, and the shaking and filtration were repeated. The process as a whole was then repeated several times until the wash-water no longer gave a test for sodium.

The precipitate was converted to a cobaltic ammine sulfate by standing for 48 hours in an ammoniacal solution of hydrogen peroxide. To recover any sulfate which might have entered into complex combination with the cobalt, the ammine was decomposed by boiling with sodium hydroxide until no more fumes of ammonia were given off. The resulting cobaltic hydroxide was then dissolved in an excess of hydrochloric acid, heated to boiling, and a hot solution of barium chloride added with constant stirring. The barium sulfate was filtered off after 24 hours. By this method the sulfide from the acido ammine gave 45.29% and 45.11% (mean 45.19%) of sulfur; that from the aquo ammine 45.10% and 45.06% (mean, 45.08%) of sulfur. The calculated percentages of sulfur in  $\text{CoS}$ ,  $\text{Co}_2\text{S}_3$ , and  $\text{CoS}_2$  are 35.16, 44.86 and 52.03 respectively. The results are evidently in very close agreement with the requirements of the formula  $\text{Co}_2\text{S}_3$ . The slight excess of sulfur which they indicate is scarcely more than the experimental inaccuracy, and is in the direction that would be anticipated, since any incompleteness either in the washing of the cobaltic sulfide or of the barium sulfate would tend to give too high values for the sulfur. Furthermore, the values for the sulfides from the acido and aquo salts are in still closer agreement, so that there can be no question but what the same sulfide is formed in each case.

Preliminary experiments showed that the heats of reaction with the sodium sulfide solution were very small; indeed so small that even with the saturated solution of the ammines the temperature change would amount to only a few thousandths of a degree. We were obliged therefore to work with a suspension of the solid ammines, although this complicated the measurements by the introduction of the unknown heats of solution. To obviate this difficulty we have made independent determinations of the heats of solution of the ammines concerned.

### Apparatus and Method.

Both the apparatus and the method employed in measuring the heats of solution and of transformation were very simple. The apparatus consisted of a 1-liter Dewar flask, almost completely submerged in a water thermostat and provided with a stopper

into which a Beckmann thermometer, a container for the powdered ammine and a rotary stirrer were fitted. The container consisted of a narrow glass tube extending through a hole in the rubber stopper with an enlarged cylindrical lower portion whose volume was about 10 cc. This enlarged portion was open at the bottom, but its lower rim was ground flat so that a thin microscope cover-glass could be tightly cemented to it. A glass rod extended through the narrow tube from above the stopper and worked tightly in a rubber packing placed at the entrance to the enlarged portion. By pushing this rod downward, the cover-glass could be broken and the cobalt ammine in the container projected into the surrounding water, or sodium sulfide solution. The method of procedure was simply to stir the measured volume of liquid in the Dewar flask until a constant rate of change was shown by the Beckmann thermometer; the weighed quantity of ammine in the container was then discharged into the liquid and the stirring and thermometer readings continued until a constant rate of temperature change had again been established. These readings were plotted, and by an inspection of the curves the temperature change produced by the solution or decomposition of the cobalt ammine could be ascertained.

Preliminary experiments showed that these temperature changes, particularly those produced by the decompositions, were still very small, even when several grams of the cobalt amines was used. This could have been partially remedied by decreasing the quantity of water, or of sodium sulfide solution, and by using a smaller Dewar flask, but this would have increased the relative uncertainty in the heat capacity of the Dewar flask. The only alternative was to reduce the experimental errors as far as possible.

The uniformity in bore and the value of a degree of the Beckmann thermometer were first investigated. Fortunately, over the range used in these experiments, the bore was quite regular, no correction greater than  $0.002^\circ$  having to be applied. By comparison at two different temperatures with a standard thermometer reading to  $0.001^\circ$ , which in turn had been compared with the primary standards at the Bureau of Standards in Washington, one degree of the Beckmann scale was found to be equivalent to  $1.014^\circ$  at  $25^\circ$  on the hydrogen scale. This correction has been applied in all the following measurements.

With such small heat changes to be measured the frictional heat produced by the stirring might evidently amount to a considerable fraction of the total heat change. This would not necessarily involve any error, for, by continuing the stirring after the reaction had ended, as outlined above, a correction could be applied to each experiment which would include both this effect and any heat change due to radiation or conduction. An error from this cause would creep in only if the rate of stirring were not sufficiently constant to prevent any perceptible variation in the rate at which the frictional heat was supplied. Experiments were therefore undertaken to determine the magnitude of the frictional heating effect and its variation with the rate of stirring.

In these experiments, the temperatures of the liquid in the flask and of the air in the room were brought to nearly the temperature of the thermostat ( $25^\circ$ ) and kept at that temperature for some time with intermittent stirring to allow a complete equalization of the temperature throughout the flask, stirrer, container and thermometer. The small stirrer was then rotated at a constant speed and readings of the Beckmann thermometer were taken at regular intervals. The speed was determined by counting the number of revolutions per minute of the belt driving the stirrer, one revolution of the belt being equivalent to about 10 revolutions of the stirrer. With 900 cc. of a sodium sulfide solution in the Dewar flask, very small heating effects were produced, but when this solution was replaced by a similar one of the same strength which had reacted with 8 g. of acido-pentammine chloride, much larger heating effects were obtained. This, however, is not surprising in view of the fine state of subdivision of the precipitate and its rather flocculent nature, for these factors doubtless increase the viscosity very consider-

ably. Indeed it is possible that the increased heating effect might be used as a means of measuring viscosity. With speeds of 50 and 104 revolutions of the belt per minute heating effects of  $0.0015^{\circ}$  and  $0.0060^{\circ}$  per minute, respectively, were obtained. Taking readings every two minutes and stirring but 10 seconds before each reading, heating effects of but  $0.0003^{\circ}$  and  $0.0008^{\circ}$ , respectively, per minute were found. As 10 seconds' intermittent stirring at the lower rate proved sufficient to give uniform temperature readings on the thermometer, this mode of stirring was adopted in all the following measurements. Although the frictional heat was evidently greatly reduced by this procedure its total effect over the 30 minute interval of an experiment was still relatively large and the effect of variation in speed of stirring upon it therefore required consideration. To determine this effect, the rates of heating in the above experiments and in other similar experiments with sodium sulfide suspensions with continuous stirring, were plotted against the rates of stirring. Nearly linear curves were obtained over the short intervals used, whose slope corresponded to an acceleration in the rate of heating of  $0.00003^{\circ}$  per minute for an acceleration in the rate of stirring of one revolution of the belt per minute; or, at a speed of 55 revolutions per minute, to about a 1% increase in the heating effect. Since a constant rate was always attained in the following experiments within 30 minutes after the introduction of the ammine, and the heating effect in the cobalt sulfide suspensions with intermittent stirring was  $0.0003^{\circ}$  per minute, an uncertainty of 10 revolutions per minute in the rate of stirring would result in an uncertainty in temperature over this interval of less than  $0.001^{\circ}$ . This constancy was easily attained even with intermittent stirring.

Similar experiments were made to test the effect of variations in the temperature of the surroundings on the temperature of the liquid in the Dewar flask. With liquid, thermostat, and air, all at very nearly  $25^{\circ}$  a constant rate of stirring was maintained for some time and regular readings of the thermometer were taken. A constant temperature change of  $0.0010^{\circ}$  per minute was obtained under these conditions. After this constant rate had been maintained for some time the temperature of the liquid in the flask was raised  $1^{\circ}$  and another series of readings made. The temperature rise was found to be  $0.0009^{\circ}$  per minute. Finally, the original temperature was re-established in the flask but the temperature of the surrounding air was lowered  $5^{\circ}$ . The consequence was a lesser rate of temperature increase, namely  $0.0003^{\circ}$  per minute. These results show that a temperature difference of  $1^{\circ}$  between the liquid in the flask and the thermostat produces a cooling effect of  $0.0001^{\circ}$  per minute, while a similar difference in temperature between the liquid in the flask and the air produces a cooling effect of  $0.00014^{\circ}$  per minute. These effects are nearly negligible, but we were careful in the following experiments to keep the temperature of the air constant to a few tenths of a degree; the thermostat was kept, of course, even more constant than this. Conduction through the neck of the flask by way of the walls, the stopper, the thermometer, etc., is evidently of somewhat more consequence than radiation and conduction across the vacuum jacket.

### Heat Capacity Determinations.

The combined heat capacity of the Dewar flask, the contained liquid, the stirrer, thermometer, etc., was determined by the electrical method. The closed container for the ammine was made into a heater for this purpose by winding non-inductively around its enlarged portion a single layer of fine, enameled, copper wire. By closing the lower end of the container and then dipping the whole in boiling asphalt, a thin, but very tough covering was secured for the coil. Indeed, this combination of asphalt and enamel was the only material we discovered which would withstand the joint action of the caustic sodium sulfide solution and the strong heating current. No change in the re-

sistance of the coil could be detected after immersion in the sodium sulfide solution for several hours with the simultaneous passage of a current of several tenths of an ampere.

We did not attempt to maintain an exactly constant current, nor to measure it precisely; instead we kept the current very nearly constant by using a storage battery, a Weston milliammeter and a slide-wire resistance, closed the circuit for a measured interval of time and determined the total quantity of electricity which had passed by means of a silver coulometer.

By this method the heat evolved was obtained from the product of the resistance of the coil and the square of the weight of silver divided by the time; all quantities which could be easily and accurately determined. Since, however, we could secure only copper wire with the requisite enamel coating and copper has the high temperature coefficient of resistance characteristic of pure metals, we were obliged to measure the resistance of the coil during the passage of the heating current under the conditions of the experiment.

For this purpose an additional, open, coil of manganin wire was introduced into the circuit next to the heating coil and immersed in a stirred oil-bath. Two relatively large manganin resistances were then shunted in series around these two coils and the middle points of these two branched circuits were connected through a galvanometer. The large resistance in the ratio arms of this Wheatstone bridge arrangement obviated possible errors due to the heating effect of the current.

It was found that the resistance of the heating coil did increase perceptibly when the current was passed. A curve was constructed connecting current strength and percentage change in resistance and from it such slight corrections as were necessary were applied for the different current strengths employed in the heat-capacity determinations. Moreover, the resistance in each case was corrected to the mean temperature of the determination.

The silver coulometer consisted of a platinum dish cathode and a silver strip anode, so that the current density was kept sufficiently low.<sup>3</sup> The silver nitrate solution contained 40 g. of salt per 100 cc., and a small porous porcelain cup served as an anode diaphragm.

The combined corrections for stirring, radiation and conduction in these heat capacity measurements, as in the subsequent calorimetric experiments, were determined in each case by taking temperature measurements over a long period before and after the heating current was applied. When these readings were plotted, the resulting curves were very smooth and permitted an accurate extrapolation over the heating interval.

Duplicate heat-capacity determinations were made, using as a liquid in the Dewar flask (1) water, (2) a 0.26 *M* solution of sodium sulfide, (3) water containing 8 g. of acido-pentammine chloride in solution and suspension and (4) the same sodium sulfide solution after it had reacted with 8 g. of the same ammine. These were the identical liquids employed in the subsequent calorimetric experiments, and in all the experiments the same volume of liquid (898 cc.) was taken, so that from these measurements, the heat capacity in every calorimetric experiment could be obtained. From the heat capacities of the calorimeter when the ammine was present the heat capacities of the calorimeter containing only the pure liquids can be calculated by subtracting the heat capacity of the ammine. The latter quantity can be calculated with sufficient accuracy for our purpose from the atomic heats of the elements concerned, and amounts to three calories for 8 g.

The results of the heat capacity measurements are given in Table I. The average deviation from the mean of the four values for water and the four values for the sodium

sulfide solution is less than 0.2%, which is no greater than the probable error of the experimental data. The mean heat capacities given in this table have been used in all the subsequent calorimetric experiments after applying a small correction for the calculated heat capacities of the added aminnes.

#### Preparation of the Aminnes.

The aminnes were prepared according to the improved methods of Jörgensen,<sup>2</sup> an imported sample of chloro-pentammine cobalt chloride, whose purity had been established by many analyses in this laboratory, serving as the starting material. Repeated analyses of salts prepared by these methods have shown them to have a high degree of purity.

#### Heats of Solution.

The general method of procedure has already been outlined in the section entitled Apparatus and Method. Before the actual determination was begun the stirrer was operated continuously for about an hour to secure a thorough equalization of temperature throughout the apparatus. The stirring was then cut down to 10 seconds before every 2-minute reading for a period of about 30 minutes, after which the ammine was ejected from its container. Continuous stirring was then maintained for a period of 1 minute, and this generally sufficed to bring the greater part of the finely-ground ammine into solution. The stirring was then reduced to its previous rate and continued until a perfectly uniform rate of temperature change had been established. This usually required but 3 or 4, and never more than 10 minutes. The effect of the regular, intermittent stirring was of course corrected for by extrapolation of the resulting curves; a special correction of 0.001° was applied for the one minute of continuous stirring, on the basis of the above preliminary experiments on the effect of stirring. A sample of the curves secured is shown in Fig. 1; the results as a whole are collected in Table II.

## Heats of Solution Calculated from Solubility Measurements.

Heats of solution are readily calculated from solubility measurements made at different temperatures by use of Van't Hoff's equation. There are difficulties, however, in applying this method to the cobalt ammines. In the first place, time is required for a precise attainment of saturation, and within this period there will be, even at 0°, a conversion of the acido (purpureo) salt into the corresponding aquo(roseo) salt, and *vice-versa*, which will vitiate the solubility measurements. In the second place, to apply Van't Hoff's equation requires a knowledge which we do not possess of the percentage dissociation of the dissolved salt. This latter difficulty can only be avoided in the case of the slightly soluble ammines whose percentage [dissociation is high, and hence can be estimated with

sufficient accuracy from the known percentage dissociation of other salts of the same type.

In view of these difficulties we have only applied this method to chloropentammine cobalt chloride, which is not only but slightly soluble, but also changes more slowly than the corresponding bromo or nitrate amines into the aquo salt. The solubility measurements on this salt were made at three temperatures, 0°, 30°, and 50°, saturation being reached from opposite sides in duplicate experiments. The salt was ground to moderate fineness before use and the suspension was rapidly stirred in a thermostat, but the results at the highest temperature were very discordant, due presumably to partial conversion into aquo salt and to incomplete saturation, and were therefore discarded. At given intervals some of the clear liquid was drawn off through a filter-pipet, its specific gravity was determined and a weighed portion was evaporated to dryness. The ammine was then converted into cobalt sulfate according to Gibbs' procedure<sup>4</sup> and weighed. The results are collected in Table III. It will

<sup>b</sup> Extrapolated to zero time in view of the evident slight formation of roseo salt.

be seen that the solubilities are concordant and independent of the time, indicating a precise attainment of saturation and a negligible conversion into aquo salt.

The heat of solution was calculated from the data given in Table IV using the equation of Van't Hoff<sup>5</sup> in its differential form where

$$L = RT^2i \left( \frac{d \log_e S}{dT} \right)$$

in which  $L$  represents the molecular heat of solution,  $R$  the gas constant,

<sup>4</sup> Gibbs, "Researches on the Ammonia Cobalt Bases," Smithsonian Contributions to Knowledge, Washington, 1856.

<sup>5</sup> Van't Hoff, *Z. physik. Chem.*, 17, 147 and 546 (1895). See also Noyes and Sammet, *Z. physik. Chem.*, 43, 513 (1903).

$i$  the Van't Hoff coefficient and  $S$  the solubility in grams per liter,  $i$  is the only term for which no immediate data are available; approximate values for it and for  $di/dt$  were obtained on the very generally justified assumption that this salt would resemble, in this respect, the similarly constituted salt, barium chloride;  $i$  and  $di/i dt$  were calculated for barium chloride from the conductivity measurements of Kohlrausch and Gruneisen,<sup>6</sup> and Deguisne,<sup>7</sup> and were found to be 2.610 and  $-0.000038$  respectively at  $25^\circ$ . To evaluate  $d \log S/dt$ , the logarithm of the observed values of  $S$  were plotted against the temperature and were found to lie on a slightly curved line. The equation for the symmetrical parabola passing most nearly through these points was then computed; it was  $\log S = 0.3517 + 0.01657 t - 0.00007054 t^2$ . This equation, when differentiated, gave  $d \log S/dt$  at  $25^\circ = 0.01304$ . Substituting these values, and  $R = 1.985$  cal. per degree and  $T = 298$  in the above equation the result  $L = 13440$  cal. was obtained, which agrees as well as could be expected with the experimentally determined value of  $12400$  cal. This is especially true when one recalls that the calculated value is the *integral* heat of solution,<sup>8</sup> while that experimentally determined is very nearly the *initial* heat of solution, and these will differ somewhat in value except in very dilute solution.

### Heats of Reaction.

The procedure in determining the heats of reaction was practically identical with that followed in the case of the heats of solution, except that a  $0.26 M$  solution of sodium sulfide was used in place of the water. The stirring was made continuous for one minute after the ejection of the ammine and a correction of  $0.001^\circ$  was applied for the extra heating effect. The temperature rise did not usually become uniform until after about 20 minutes; probably the particles of the ammine became coated with a layer of the sulfide. Temperature readings were then continued for some 40 minutes to obtain with certainty the temperature rise per minute. The readings of a typical experiment are plotted in Curve II of Fig. 1. The results of all measurements are collected in Table IV. It will be seen from this table that the average discrepancy between the heat capacities found in duplicate experiments corresponds to an average discrepancy in the temperature change of about  $0.001^\circ$ . It will also be seen that in some cases the reaction is decidedly exothermic, in others endothermic.

By subtracting the heats of solution from the heats of reaction of the solid salts the heats of reaction in solution may be obtained. By subtracting the heats of reaction of the aquo from the corresponding acido salts in solution the heats of transformation are finally obtained. The results of these calculations are collected in Table V.

TABLE V.

HEATS OF REACTION AND TRANSFORMATION OF PENTAMMINE COBALT SALTS IN AQUEOUS SOLUTION AT 25°.

Ammine.	Heat of reaction. Cals.	Heat of transformation. Cals.
Chloro chloride.....	15070	2140
Aquo chloride.....	12930	
Bromo bromide.....	13290	1690
Aquo bromide.....	11600	
Nitrato nitrate.....	12340	480
Aquo nitrate.....	11860	

### Discussion of Results.

The heats of transformation are in reverse order as compared with the velocities of transformation;<sup>1</sup> that is, of the ammines the chloro changes the least rapidly, the bromo next, and the nitrato the most rapidly into the corresponding aquo compound. They follow, in all probability, the same reverse order as compared to the free energy of transformation, although this latter quantity has only been measured in the case of the chloride and bromide. This is of interest, because not only are the magnitude and sign of the heat of transformation the same as has been found for the heats of ionization of salts in water but there, too, the more highly dissociated have, in general, the lesser heats of ionization. All

of these considerations seem then to emphasize the similarity pointed out before between the transformation of the acido (purpureo)-pentammine salts in aqueous solution into the aquo(roseo)-pentammine salts and the electrolytic dissociation of the strong electrolytes in water.

### Summary.

1. A method of calorimetry has been developed in which only observations on a silver coulometer, and of time and electrical resistance are required.

2. It has been shown that the same sulfide of cobalt ( $\text{Co}_2\text{S}_3$ ) is produced by the action of sodium sulfide on chloro- and aquo-pentammine cobalt chloride in aqueous solution.

3. The solubility of chloro-pentammine cobaltic chloride has been measured at several temperatures, and its heat of solution has been computed from these data, and found to be in fair agreement with the directly measured values.

4. The heats of solution in water of a number of acido- and aquo-pentammine cobaltic salts, and their heats of reaction with aqueous solutions of sodium sulfide have been measured. From these data the heats of transformation of the solid acido to the corresponding solid aquo amines have been calculated.

5. The heats of transformation have been found to be antibat to the velocities of transformation, but probably symbat to the free energies of transformation, a reaction similar to that shown by the ionization of salts in water.

CAMBRIDGE 38, MASSACHUSETTS,  
AND NEW YORK CITY.

### NOTE.

**An Interesting Colloid Gel.**<sup>1</sup>—The structure of gels has been a question which has given rise to numerous investigations and we are still far from unanimity of opinion. Probably one of the factors which contributes to the difficulties of the problem is the complexity of the disperse material. Gelatin, for example, has been used in many investigations, but when we realize how inadequate our knowledge is regarding the chemical configuration of the gelatin molecule, and how easily proteins may be altered by physical or chemical factors, it is not surprising that the experimental results have been found to differ widely when different samples of gelatin are used. The same objections apply to agar-agar as apply to gelatin.

Aside from the complex organic substances, such as proteins, gums,

<sup>1</sup> Published with the approval of the Director as Paper No. 263, *Journal Series*, Minnesota Agricultural Experiment Station.

polysaccharides, etc., which show more or less true gel formation, we have silicic acid gels. Here again we have a material of more or less unknown composition. The method of preparing the sodium silicate sol and its past history as well as the concentration of acid by which it is converted into the silicic acid gel all play a part in the properties and behavior of the final gel.

There thus appears to be a need for some substance which can be prepared by anyone in pure form and which will easily set to a rigid gel. We believe that the dibenzoyl derivative of the amino acid *l*-cystine satisfactorily meets all of these requirements.

**Preparation of dibenzoyl-*l*-cystine.**—Two g. of cystine (prepared from human hair by hydrolysis with hydrochloric acid) was suspended in 100 cc. of water, and sufficient 10% sodium hydroxide solution was added to dissolve the amino acid. Ten g. of benzoyl chloride was then added and enough additional sodium hydroxide (in solution) to make a total of 6 g. The mixture was shaken vigorously until all odor of benzoyl chloride had disappeared. Upon acidification with hydrochloric acid the entire solution set to a stiff gel. This was broken up by agitation and thrown upon a Büchner funnel, and the liquid drained off by a strong suction. After filtering for several hours a felt of crystals of the benzoyl derivative remained upon the filter. This was washed with water and recrystallized from somewhat diluted alcohol, yielding long silky needles melting at 180–181° (uncorr.). Brenzinger<sup>2</sup> gives 180–181° (uncorr.) as the melting point of pure benzoyl cystine, whereas Goldmann and Baumann<sup>3</sup> give 156–158°. Undoubtedly 180–181° is the correct value.

*Dibenzoyl cystine is insoluble in water, does not contain water of crystallization and in the crystalline state, at least, has no hydrophilic properties. It is readily soluble in most of the organic solvents and because of the presence of the benzoyl groups it is a relatively strong organic acid.*

At the time we prepared our compound we had not consulted Brenzinger's paper but were relying on the data as given in various texts and handbooks. None of those consulted emphasized the gel-forming property. After we had prepared several samples of benzoyl cystine and had particularly investigated its gel-forming properties, we consulted Brenzinger's paper and found that he had recorded the gel formation. He states that if the alkaline solution of benzoyl cystine prepared from 2 g. of cystine as noted above is diluted to 3 liters before acidification with hydrochloric acid, the resulting mixture will be a rigid gel from which no water can be poured. Assuming a quantitative conversion of the cystine into the benzoyl derivative such a gel would have a concentration of 0.124% of benzoyl cystine.

Undoubtedly this observation of Brenzinger's would have attracted the attention of colloid chemists had it not been published at so early a date. The peculiar gel-forming properties of the substance led us to study it further. We found that we could readily prepare a rigid gel in

<sup>2</sup> Brenzinger, *Z. physiol. Chem.*, **16**, 537 (1892).

<sup>3</sup> Goldmann and Baumann, *ibid.*, **12**, 255 (1888).

which the concentration of the dibenzoyl derivative did not exceed 0.2% and that a gel of 0.1% concentration was rigid enough to hold its shape for a minute or more when the beaker containing the gel was inverted. We believe that these are the most dilute rigid gels that have ever been prepared artificially. Gelatin and silicic acid gels require considerably higher concentrations of the colloid material and even the natural gel in which frog eggs and salamander eggs are embedded and the natural gel of the jelly fish contain more solid material.

**The Preparation of a 0.2% gel.**—Two-tenths g. of pure benzoyl cystine was dissolved in a beaker in 5 cc. of 95% alcohol. While the contents were kept boiling hot, water was added until a volume of 100 cc. had been attained. At this point there was a slight opalescence but no evidence of precipitation or gel formation. The beaker was then covered and set aside to cool. In a short time, usually 2 to 3 hours but occasionally longer, the entire mass had set to a rigid gel comparable to a 5% gelatin gel. In no case was gel formation observed until a considerable period had elapsed after the contents of the beaker reached room temperature.

**Properties of the Gel.**—The gel was practically transparent, no change in opalescence being observed beyond that exhibited by the freshly prepared sol. The gel can be loosened from the walls of the beaker and will support its own weight for a long time. The beaker containing the gel may be left inverted for several hours without breaking the gel. However, in the course of several days some changes take place. The most noticeable one is the formation of opaque nuclei caused apparently by the aggregation of minute stellate groups of needles throughout the gel structure. This phenomenon is accompanied by syneresis or "bleeding" of the gel so that in the course of several weeks most of the benzoyl-cystine has separated in a definitely crystalline condition. When the freshly prepared gel is thrown upon a filter in a Büchner funnel and strong suction is applied, a limpid liquid filters slowly through and the benzoyl cystine remains practically quantitatively on the filter. Usually 8 to 10 hours are required to filter the liquid from 100 cc. of the gel. After filtration the thin "skin" of benzoyl cystine may easily be separated from the filter paper.

**The Structure of the Gel.**—The fact that the benzoyl-cystine may be filtered from the freshly prepared gel by the use of ordinary filter paper and suction argues for a relatively coarse degree of dispersion. Unfortunately we do not have access to a Zsigmondy ultramicroscope so that we are still somewhat in doubt as to the true gel structure. When a portion of the gel is viewed by dark-field illumination,<sup>4</sup> using a 4 mm. objective

<sup>4</sup> Using a Wenham-Sidentopf paraboloid and a special slide similar to that described by Lord (*J. Agr. Res.*, 17, 170 (1919)) with the exception that the cavity in the slide was sufficiently large to allow the insertion of a portion of the gel approximating 5 × 5 mm, surface area and 1 mm. in thickness.

and 12.5 ocular, one observes a fibrillar structure as if the gel were composed of needle crystals of exceedingly small cross section. In fact, the cross section of the fiber is so small as to not be apparent when an oil immersion objective (1.9 mm. fluorite) was used. These fibrillar areas, however, could not be demonstrated to be continuous throughout the gel structure. In certain of our preparations they appeared to be discontinuous and surrounded by an area of approximately equal extent which was optically void. It is possible that the fibers were present in such an area, but we could not demonstrate them with our relatively crude ultramicroscope. Then again the areas in which the fibers could be demonstrated may possibly have been formed by crystal growth following the true gel formation, and may not be essential to the gel structure. Certain of the fibrillar areas apparently grow in opacity and size as the gel ages, serving as nuclei for the crystalline benzoyl-cystine noted earlier. This growth is however to be expected from the Noyes-Nernst rule governing the growth of crystals.

All of the available evidence, however, points to the benzoyl-cystine gel as having a fibrillar structure, the fibrils being exceedingly minute crystals of benzoyl-cystine. The evidence is incomplete, but if 0.2 g. of the non-hydrophilic benzoyl-cystine can form a crystal gel retaining 100 g. of water, such a phenomenon certainly has a profound bearing on the subject of gel formation and gel structure in other systems.

## THE RELATION BETWEEN THE MODE OF SYNTHESIS AND TOXICITY OF ARSPHENAMINE AND RELATED COMPOUNDS.<sup>1</sup>

BY WALTER G. CHRISTIANSEN.

Received June 21, 1921.

In the oldest and probably the most widely used method of preparing arspenamine, 3-nitro-4-hydroxy-phenylarsonic acid is reduced by sodium hydrosulfite directly to arspenamine base which is then converted into the dihydrochloride by solution in methyl-alcoholic hydrochloric acid and precipitated with ether. This procedure has led to wide variations in the toxicity of the product; some preparations kill at doses as low as 60 mg./kg., whereas others do not kill at 130 or 140 mg./kg. Believing that some

<sup>1</sup> This is the fourth of a series of studies on the properties contributing to the toxicity of arspenamine being made under a grant from the United States Interdepartmental Social Hygiene Board to the Harvard Medical School; the work is under the general

condition or set of conditions controlled the toxicity, a detailed investigation of the arspenamine synthesis was undertaken. The toxicity discussed in this paper is that described under Type II in a paper by Dr. Reid Hunt<sup>2</sup> and is quite different from that due to the presence of 3-amino-4-hydroxyphenyl-arsenious oxide or to the physical nature of the solution.

The nitrohydroxy acid is obtainable by three commercially feasible processes,<sup>3</sup> and it was found that relatively toxic and nontoxic arspenamine could be obtained from crude or purified nitro acid regardless of the method by which the latter was made. Moreover, the replacement of as much as 5% of the nitro acid by substances which might be present as impurities, *e. g.*, 3,5-dinitro-4-hydroxy-phenylarsonic acid, *o*-nitro-*p*-cresolarsonic acid, or a mixture of 3-nitro- and 5-nitro-2-hydroxy-phenylarsonic acids, caused only slight variations in the toxicity of the resulting arspenamine. In this connection attention should be called to the fact that the presence of the dinitro acid, as an impurity, would lead to the formation of a tri-amino and not a tetra-amino arseno compound as has been suggested. This is a consequence of the formation of an unsymmetrical arseno compound in preference to two symmetrical ones when a mixture of two different arsonic acids is reduced. Previous investigators<sup>4</sup> have mentioned this, and work done in this laboratory is entirely in agreement with that of the others.<sup>5</sup>

Investigation of methods available for the conversion of the base into the dihydrochloride<sup>6</sup> revealed nothing which caused distinct variations in toxicity. In fact, when a sample of the base was converted half into the dihydrochloride by the methyl-alcohol-ether method and half into the dihydrosulfate by precipitation of the latter from a dilute solution of the base in aqueous hydrochloric acid with dil. sulfuric acid the two substances had identical toxicities. In another experiment, the dihydrochloride was dissolved in methyl alcohol and reprecipitated with ether in accordance with the direction of Dr. Reid Hunt, who is also responsible for the biological tests reported in this paper. Additional aid has been received from the Committee of the Permanent Charity Fund, Incorp.

<sup>2</sup> Hunt, *J. Am. Med. Assoc.*, **76**, 854 (1921).

<sup>3</sup> For an outline of these syntheses see Lythgoe, *Chem. Age* (N. Y.), **28**, 390 (1920).

<sup>4</sup> Bertheim, *Chem. Ztg.*, **38**, 756 (1914); Karrer, *Ber.*, **49**, 1648 (1916); Fargher, *J. Chem. Soc.*, **118**, 865 (1920).

<sup>5</sup> The reduction of equivalent quantities of *p*-hydroxy-phenylarsonic acid and its mononitro or mono-amino derivative gave no acid insoluble arseno compound; the only substance obtained gave a hydrochloride which analyzed for mono-amino-dihydroxy-arsenobenzene hydrochloride. Also, the reduction of equivalent quantities of 3-nitro- or 3-amino-4-methoxy-phenylarsonic acid and 3-amino- or 3,5-dinitro-4-hydroxy-phenylarsonic acid gave no alkali-insoluble arseno compound. These results could be obtained only by the formation of an unsymmetrical molecule.

<sup>6</sup> Ehrlich and Bertheim, *Ber.*, **45**, 756 (1912); Kober, *This Journal*, **41**, 442 (1919).

without any alteration in toxicity. Another portion was converted into the base by treating an aqueous solution with sodium carbonate and the toxicity of the base was equivalent to that of the original hydrochloride.

These results indicate that the toxicity of the arsphenamine is determined during the reduction of the nitrohydroxy acid to arsphenamine base and is not dependent upon the character or source of the nitro compound or upon the conversion of the base into the dihydrochloride.

Examination of the reaction by which arsphenamine base is obtained shows the presence of several known intermediates and the opportunities for undesired side reactions to occur.

At this point in the work the average tolerated dose of a large number of preparations made from the nitro compound by the standard method of reduction was 110 mg./kg.<sup>7</sup> and varied between 70 and 140 mg./kg. When the pure amino acid, from various sources, was reduced under the same set of conditions the arsphenamine consistently had a tolerated dose of 140–150 mg./kg. This figure agrees well with those obtained for arsphenamine prepared from the pure amino acid by other methods<sup>8</sup> and is probably as high as can be attained with any degree of regularity. Hydrosulfite reduction of the pure arsenious oxide gave a product tolerated in doses of approximately 130 mg./kg. It is evident from the wide variations encountered when the nitro acid is the starting material, from the consistency with which an excellent product may be secured by reducing the amino acid by the same method used for the nitro acid, and from the fact that the mechanism of the reaction is the same in both cases after the nitro group has been reduced, that the toxicity of the arsphenamine obtained by hydrosulfite reduction depends upon some variable process in the formation of the amino group. Later, when methods had been developed for the consistent production, from the nitro acid, of arsphenamine with a tolerated dose as low as 50–70 mg./kg., the application of these methods to the reduction of the pure amino acid gave a product with a tolerated dose of approximately 140 mg./kg.

That the toxicity of arsphenamine should be closely bound up with the reduction of the nitro group is not surprising when one considers the many intermediates and by-products encountered in the reduction of nitro compounds. When the quantities of reagents used in this reduction were

<sup>7</sup> The average tolerated dose of the arsphenamine of 6 manufacturers was found by Schamberg, Kolmer, and Raiziss, *Am. J. Med. Sci.*, **160**, 188 (1920), to be 105 mg./kg.

<sup>8</sup> Christiansen, *THIS JOURNAL*, **42**, 2402 (1920); **43**, 370 (1921).

varied no alterations were found in the toxicity of the resulting arspenamine, but as soon as variations were made in the conditions under which the reaction took place marked variations in toxicity were obtained. Ultimately it was determined that the important factors are the degree to which high local concentrations of the nitro compound momentarily exist at the start of the reduction, the temperature at which the nitro group is reduced, and the speed at which the solution, after the reduction of the nitro group, is raised to 55°. When this point in the reaction is reached, the toxicity of the arspenamine which will be produced has been settled. The procedure best suited for the development of low toxicity is very vigorous mechanical stirring while a cold solution of the nitro compound is slowly added to a cold solution of magnesium chloride and sodium hydrosulfite followed by rapid heating to 55°. Obviously the reverse conditions tend to develop high toxicity. That the degree of agitation affects the toxicity only at the time of reduction of the nitro group is shown by the fact that as soon as the color of the nitro group has been destroyed the rate of stirring can be increased to that used for the preparation of arspenamine of low toxicity without decreasing the toxicity of the material.

The influence of each of these conditions is shown in the following table. When nothing is specified it indicates that the importance of the condition had not been discovered and was only approximately constant in successive experiments. All experiments recorded here were conducted identically after 55° had been reached.

TABLE I.  
INFLUENCE OF CONDITIONS OF PREPARATION UPON TOXICITY.

Rate of stirring.	Rate of addition of nitro solution.	Temp. of solutions. ° C.	Rate of heating.	Expt.	Average tol. dose. Mg./kg.	Limit of tol. dose. Mg./kg.	Average as content. %
R <sup>a</sup>	..	..	..	10	110	100-120	30.27

<sup>a</sup> R = Rapid.

<sup>b</sup> S = Slow.

<sup>c</sup> This series includes preparations made: (a) from crude and recrystallized nitro acid made from phenol; (b) from recrystallized nitro acid made from aniline by the oxalyl method; (c) with different commercial brands of hydrosulfite; (d) by different methods of conversion of the base into the dihydrochloride.

<sup>d</sup> This series includes preparations made from crude nitro acid made from phenol and from aniline by the oxalyl method.

Since it has been established that the crucial part of the synthesis lies in the reduction of the nitro group, preliminary work has been done toward ascertaining what undesired secondary process takes place during this reaction. The nitro acid was reduced with hydrosulfite between  $-10^{\circ}$  and  $0$ , in order to slow down this very exothermic reaction and produce conditions similar to prolonged high local concentrations of the nitro compound in the presence of hydrosulfite. The crude amino acid, after isolation, was further reduced with hydrosulfite and yielded arspphenamine tolerated in doses of 120–130 mg./kg. However, when a small quantity of pure amino acid was added to the mother liquor from the crude amino acid separated above and the solution reduced with hydrosulfite, the arspphenamine obtained had a tolerated dose of about 53 mg./kg.; this is the average of 11 experiments in which the tolerated dose varied from 30 to 70. It is evident that the secondary reduction product remains for the most part in the solution when the crude amino acid is isolated. The small quantity of pure amino acid was added to the mother liquor in order that the secondary reduction product may unite, upon reduction, with a molecule of pure amino acid to form the unsymmetrical arseno compound since this is what must happen in the formation of arspphenamine where the ratio of the amino acid to the secondary product is large.

A number of experiments have been made with this solution apparently containing the secondary reduction product and work is now in progress toward the determination of the nature of this product.

The following explanation for the variations found in the toxicity of arspphenamine is suggested.

The toxicity of arspphenamine depends upon the quantity of (III) present, which in turn depends upon the amount of (II) formed at the beginning of the reaction and this is very variable. By regulation of the conditions as discussed above the formation of (II) can be accelerated or retarded but apparently not always entirely inhibited because the average of the best preparations from the nitro acid is below that of preparations from the amino acid. The success of the arspphenamine synthesis is due to the fact that (I) is the major and (II) the minor reduction product.

In order to verify this explanation and to see whether it could be applied to substances related to arspphenamine, mono-, tri-, and tetra- amino dihydroxy-arsenobenzenes were prepared from the nitro and amino acids.

In each case the products prepared by reduction of the amino aryl arsonic acids were less toxic than those prepared from the analogous nitro acids. Interesting biological observations on the effect of increasing the number of amino groups in the hydroxy-arsenobenzene have been made by Drs. Reid Hunt and G. P. Grabfield.<sup>9</sup>

In general the amino arseno compounds vary in toxicity according to the methods of preparation and are obtained in the purest form by reduction of amino arsonic acids. When the nitro acids serve as the starting material more toxic products result owing to the formation of secondary reduction products during the reduction of the nitro group.

The toxicity determinations were made by intravenous injection into white rats and the arsenic determinations by a modification of Lehmann's method.

Fargher and Pyman,<sup>10</sup> in a paper on the "Composition of Salvarsan," showed that arspenamine contains two molecules of water of crystallization and small variable amounts of occluded methyl alcohol. In this laboratory 4 carefully prepared samples of arspenamine base were found to contain the following percentages of arsenic: 37.33, 38.68, 37.78, 38.96; and one sample prepared by precipitation of an aqueous solution of the dihydrochloride with sodium carbonate contained 37.39%. The calculated percentage for  $C_{12}H_{12}O_2N_2As_2$  is 40.98; for 1  $H_2O$ , 39.06; for 2  $H_2O$ , 37.32. Apparently water in variable amounts is firmly attached to the base when the latter forms and is not lost during the drying at room temperature or conversion into the dihydrochloride. If some phenomenon like this did not occur it would be hard to understand how a seemingly dry product when dissolved in anhydrous alcoholic solutions and precipitated with ether could obtain water of crystallization.

In the cases reported in this paper of compounds very closely related to arspenamine the calculated and actual arsenic contents agree well if it is assumed that these substances also have 2 molecules of water of crystallization.

### Experimental.

#### Reduction of 3-Nitro-4-hydroxy-phenylarsonic Acid to Arspenamine.

A. To a solution of 5.3 g. of magnesium chloride hexahydrate in 130 cc. of water at 8°, 30 g. of sodium hydrosulfite is added and a cold (8°) solution of 2 g. of the nitro acid in 46 cc. of water containing 0.66 g. of sodium hydroxide is added gradually during 1-1.5 min. with very vigorous mechanical stirring. One g. of Superfiltchar<sup>11</sup> is added and the mixture is heated to 40° as rapidly as possible and then filtered.<sup>12</sup> The

<sup>9</sup> These observations will be published in a later paper.

<sup>10</sup> Fargher and Pyman, *J. Chem. Soc.*, 117, 370 (1920).

<sup>11</sup> A high grade of vegetable decolorizing carbon, a supply of which was placed at our disposal by the Industrial Chemical Co., N. Y.

<sup>12</sup> Filtering at this point as suggested by Kober, Ref. 6, is of great assistance since it renders the subsequent conversion of the base into the hydrochloride much easier. The carbon helps to remove the more finely divided insoluble matter which often tends to pass through the filter but does not seem to have any bearing upon the toxicity of the arspenamine.

clear colorless filtrate is rapidly heated with stirring to 55° and maintained at 55–60° for 90 minutes. The base is removed by filtration and, after washing and drying *in vacuo* over caustic soda, is converted into the dihydrochloride by dissolving in 7.5 cc., of absolute methyl alcohol containing the calculated amount of dry hydrogen chloride filtering and pouring into 10 volumes of ether<sup>13</sup> cooled to 0–5°. The precipitate is washed with ether and dried *in vacuo* over caustic soda. Yield, 1.2 g. of yellow powder easily soluble in water. Five experiments gave a product which had an average tolerated dose of 130 mg./kg. and arsenic content of 31.15%; that calculated for  $C_{12}H_{14}O_2N_2Cl_2As_2 \cdot 2H_2O$  is 31.58%.

B. The quantities are the same as in A., but the solutions are brought to 30° before mixing, the stirring is very slow when the hydrosulfite and nitro solution are added, and the latter is added in 5 seconds. As soon as the color due to the nitro group disappears the rate of stirring is increased to that used in A and as soon as the hydrosulfite has completely dissolved the material is filtered.<sup>14</sup> The filtrate is heated to 55° during 40 minutes with vigorous stirring and maintained at 55–60° for 1.5 hours. The remaining part of the experiment is like A. The product of 2 experiments gave an average tolerated dose of 55 mg./kg., and arsenic content of 29.82%.

#### Reduction of 3-Amino-4-hydroxy-phenylarsonic Acid.

In this process there is no particular need of careful attention to the details at the beginning as no reaction occurs until the solution has become hot.

To a solution of 5.3 g. of magnesium chloride hexahydrate in 130 cc. of water, 25 g. of sodium hydrosulfite is added with stirring and then a solution of 1.8 g. of the pure amino acid in 40 cc. of water and 5 cc. of saturated sodium carbonate<sup>15</sup> solution. The solution is heated to 30°, filtered, and the experiment is completed as in the other cases. Yield, 1.46 g. of yellow powder easily soluble in water. Four experiments gave a product having an average tolerated dose of 140–150 mg./kg. and arsenic content of 31.55%.

#### Reduction of the Nitro Acid to the Amino Acid.

A solution of 2 g. of the nitro-hydroxy-phenylarsonic acid in 15 cc. of water and 1.5 cc. of sodium hydroxide (sp. gr. 1.295) is cooled in a freezing mixture (–16°) with rapid stirring. At about –2° the sodium salt of the nitro acid separates as fine crystals, with the evolution of heat. When the mush is at about –3°, 5 g. of hydrosulfite is added, the heat generated is partly absorbed as the nitro compound redissolves and if the freezing mixture is efficient the temperature can be kept below 0°. After the color of the nitro group has disappeared the temperature falls to –10°, and the amino acid starts to separate. At the end of ½ hour 0.6 cc. of glacial acetic acid is added and the material is left in the ice box for 1 hour. After filtration, washing, and air-drying, 1.2 g. of the crude amino acid is obtained.

The mother liquor is treated with 1.5 cc. of sodium hydroxide, and a solution of 0.5 g. of pure amino acid in 10 cc. of water and 1.5 cc. of saturated sodium carbonate solution is added. This solution is added to one of 2.6 g. of magnesium chloride hexahydrate in 20 cc. of water to which 11 g. of hydrosulfite has been added. The reduction and conversion of the base into the dihydrochloride is carried out as in the case of the pure amino acid. The average of the products from 9 experiments is 0.2 g. of brownish-yellow powder which dissolves very readily in water and is tolerated in doses of 53 mg./kg.

<sup>13</sup> Absolute ether is unnecessary.

<sup>14</sup> Carbon is not necessary as the fine particles coagulate rapidly at this temperature and are easily filtered out.

<sup>15</sup> Sodium carbonate is used in place of hydroxide as the aminohydroxy acid oxidizes much less rapidly in the carbonate solution.

Reduction of the crude amino acid by the method used for the pure acid gives 1.3 g. of arspphenamine with a tolerated dose of 120 mg./kg. or above and an arsenic content of 31.05%.

### 3-Amino-4,4'-dihydroxy-arsenobenzene Hydrochloride.

I. A mixture of 0.9 g. of anhydrous monosodium *p*-hydroxy-phenylarsonate and 0.9 g. of 3-amino-4-hydroxy-phenylarsonic acid is reduced by the method used in preparing arspphenamine from the amino acid. One and one-tenth g. of base is obtained which is completely soluble in acids. When a filtered methyl-alcoholic solution of the hydrochloride is poured into ether an oily substance separates which after decantation of the ether is dissolved in water and precipitated by pouring into 1:1 hydrochloric acid. After filtering, washing with acid and drying *in vacuo* over caustic soda, 0.7 g. of reddish-orange powder is secured which is soluble in water and is tolerated in doses above 130 mg./kg.

*Analysis.* Calc. for  $C_{12}H_{12}O_2NCIAs_2 \cdot 2H_2O$ : As, 35.43. Found: 35.39.

II. A mixture of 0.9 g. of monosodium *p*-hydroxy-phenylarsonate and 1 g. of 3-nitro-4-hydroxy-phenylarsonic acid is reduced by Method A used to prepare arspphenamine from the nitro acid but without using carbon, without particularly rapid heating to 55°, and filtering at 30° instead of 40°. <sup>16</sup> One g. of tan colored base is obtained. By dissolving it in 30 cc. of water and 0.3 cc. hydrochloric acid (sp. gr. 1.19) and pouring the filtered and cooled solution into 60 cc. of cold 1:1 hydrochloric acid the hydrochloride is precipitated. Continuing as in Procedure I one obtains 0.9 g. of reddish-orange solid, the tolerated dose of which is 120 mg./kg., and whose arsenic content is 36.12%.

III. The mixture of nitrohydroxy and hydroxy acids is reduced by Method B for the preparation of arspphenamine from the nitro acid but the filtered solution is not heated particularly slowly to 55°. The hydrochloride is obtained as above. Yield: 0.8 g. of reddish-orange solid which is tolerated in doses of 80 mg./kg. and has an arsenic content of 35.98%.

In each of the following experiments the arseno base is converted into the hydrochloride by the methyl alcohol-ether method used for arspphenamine.

### 3,5,3'-Tri-amino-4,4'-dihydroxy-arsenobenzene Trihydrochloride.

I. A mixture of 0.9 g. of 3-amino-4-hydroxy-phenylarsonic acid and 0.95 g. of 3,5-diamino-4-hydroxy-phenylarsonic acid is reduced by the method used to reduce the mono-amino acid to arspphenamine. Yield, 1.5 g. of yellow powder which is very readily soluble in water and is tolerated in doses of 80 mg./kg.

*Analysis.* Calc. for  $C_{12}H_{10}O_2N_3Cl_3As_2 \cdot 2H_2O$ : As, 28.49. Found: 28.68.

II. A mixture of 1 g. of 3-nitro-4-hydroxy-phenylarsonic acid and 1.17 g. of 3,5-dinitro-4-hydroxy-phenylarsonic acid is reduced as in Preparation II of the mono-amino dihydroxy-arsenobenzene. Yield, 1.2 g. having a tolerated dose of 80 mg./kg. and an arsenic content of 28.23%.

III. The above mixture of mono- and dinitro acids is reduced as in Preparation III of the mono-amino-dihydroxy-arsenobenzene. Yield, 1.15 g.; tolerated dose, 60 mg./kg.; arsenic content, 28.70%.

### 3,3',5,5'-Tetra-amino-4,4'-dihydroxy-arsenobenzene Tetrahydrochloride.

In the following experiments only that portion of the base soluble in methyl alcoholic hydrochloric acid<sup>17</sup> was used.

<sup>16</sup> This work was done before the influence of the rate of heating had been investigated.

<sup>17</sup> Raiziss and Gavron, *THIS JOURNAL*, 43, 582 (1921).

I. One and nine-tenths g. of 3,5-diamino-4-hydroxy-phenylarsonic acid is reduced by the method used in reducing the mono-amino acid to arsphenamine. Yield, 0.6 g. yellow powder which is very easily soluble in water and which is tolerated in doses of 70 mg./kg.

*Analysis.* Calc. for  $C_{12}H_{13}O_2N_4Cl_4As_2 \cdot 1H_2O$ : As, 26.78; calc. for  $2H_2O$ : 25.95. Found: 27.29.

II. Two and three-tenths g. of 3,5-dinitro-4-hydroxy-phenylarsonic acid is reduced as in Preparation II of the mono-amino analog. Yield, 0.4 g.; tolerated dose, questionable at 50 mg./kg.; arsenic content, 25.55%.

III. The dinitro acid is reduced as in Preparation III of the mono-amino analog. Yield, 0.4 g.; tolerated dose, 50 mg./kg.; arsenic content, 26.10%.

### Summary.

1. It has been proved that the toxicity of arsphenamine prepared by hydrosulfite reduction of 3-nitro-4-hydroxy-phenylarsonic acid is determined during the reduction of the nitro group.

2. By altering the conditions under which the nitro group is reduced the toxicity of the arsphenamine can be made to fluctuate between wide limits. Two sets of conditions have been determined which enable one to produce arsphenamine of widely different toxicity; one set results in a tolerated dose of 130 mg./kg. and the other of 55 mg./kg.

3. For the consistent production of arsphenamine of the lowest toxicity it is advisable to use pure 3-amino-4-hydroxy-phenylarsonic acid as the starting material.

4. It appears to be general that the amino aryl arseno compounds vary in toxicity with the method of preparation and are obtained in the least toxic condition by the reduction of amino arsonic acids. Due to the formation of by-products during the reduction of the nitro group, more toxic products result if the nitro acids serve as the starting material. These secondary reduction products unite with the amino acid in the subsequent reduction of the arsonic acid group to form unsymmetrical arseno compounds.

I take this opportunity to thank Dr. Reid Hunt for his kindness in determining the toxicity of the large number of samples involved in this work, and Miss Helen A. Pratt for her careful work in preparing some of the intermediates used.

**CHLORINATION AND THE FORMATION OF CHLORO-AMINES  
BY MEANS OF NITROGEN TRICHLORIDE.<sup>1</sup>**

BY GEORGE H. COLEMAN WITH WILLIAM ALBERT NOYES.

Received June 27, 1921.

**Introduction.**

The investigation was first undertaken in the hope that it might have a bearing on the general question of the positive and negative character of atoms in combination.

A study of the reaction between nitrogen trichloride and ethyl bromide was made with the thought that it might yield triethylamine and free chlorine and bromine, or perhaps a chlorobromine compound. A reaction of this kind would, of course, be of much interest in relation to the general problem. Ethyl iodide was first used, but it was found very difficult to control the reaction. The work was therefore carried out with ethyl bromide.

No evidence was found of the formation of an amine. The products of the reaction were ammonium chloride, nitrogen, chlorine, bromine, and a small amount of a high-boiling liquid residue left upon distillation of the ethyl bromide. That the nitrogen trichloride did act as a chlorinating agent to a slight extent was evidenced by an analysis of the three principal fractions of the high-boiling residue. The results seemed to indicate that these products were not the same as those found when Lescoeur<sup>2</sup> studied the action of chlorine on ethyl bromide.

To determine whether or not nitrogen trichloride differs from free chlorine in its chlorinating action, the investigation was continued. Ethyl chloride was used in place of ethyl bromide in order to simplify the identifications of the products.

With the thought of extending the work to a different class of compounds, the reaction of nitrogen trichloride was also tried with toluene, with benzene, and with benzyl chloride. In each case, a very unexpected result was obtained in that, along with other products of the reaction, small amounts of chlorinated amines were formed.

**Theoretical.**

**I. Chlorination.**—The work with nitrogen trichloride and ethyl chloride was carried out as that with the ethyl bromide had been, without exposure to light other than dim artificial light. The products of the

<sup>1</sup> Abstract of a thesis presented to the Graduate Faculty of the University of Illinois in partial fulfillment of the requirements for the degree of Doctor of Philosophy.

<sup>2</sup> Lescoeur, *Bull. soc. chim.*, 29, 483 (1878).

reaction were similar to those obtained with the ethyl bromide. The most interesting and significant feature of the work with this compound, however, was the fact that, in addition to the usual products of the action of chlorine on ethyl chloride, the high-boiling residue contained a relatively large amount of ethylene chloride.

It has been quite well established that ethylene chloride is not a product of the chlorinating action of free chlorine on ethyl chloride in the absence of a catalytic agent. As the products of this reaction, Regnault<sup>3</sup> found ethylidene chloride, together with several higher chlorinated derivatives of ethane, but no ethylene chloride. Damoiseau,<sup>4</sup> although his experiments were performed at a higher temperature, found no ethylene chloride. Geuther<sup>5</sup> apparently found traces of ethylene chloride in his product, but thought it was due to impurities in the ethyl chloride used. Städel<sup>6</sup> prepared 5 kg. of the reaction product, which on careful fractionation, gave no evidence of ethylene chloride. Denzel<sup>7</sup> also secured the same result. However, Victor Meyer and Müller<sup>8</sup> did prepare ethylene chloride from ethyl chloride by heating equivalent amounts of antimony pentachloride and ethyl chloride at 100° in sealed tubes. They also prepared ethylene bromide from ethyl bromide and bromine, with iron filings as a catalytic agent.

As mentioned above, the work with the aromatic compounds was undertaken with the thought of studying the chlorinating action of nitrogen trichloride on a different class of substances. In the case of toluene, it was found that the high-boiling residue left on distillation of the toluene consisted of a mixture of monochloro-toluenes and benzyl chloride together with higher chlorinated products. Hentschel<sup>9</sup> found benzene hexachloride as the product of the action of nitrogen trichloride on benzene in the sunlight. It might be pointed out in this connection that sunlight decomposes nitrogen trichloride rapidly. Probably this product was formed by the action of free chlorine on the benzene. Benzene hexachloride was also found to be the main chlorination product of the trichloride with benzene in this investigation. Although in most cases, the reaction was carried out in the dark, an excess of chlorine was present in the solution soon after its preparation, as a result of the decomposition of the trichloride.

**II. Chloro-amines.**—In all the reactions studied, a white precipitate containing ammonium chloride was formed. In the case of toluene, of benzene and of benzyl chloride, when this white precipitate was dissolved in water and an alkali was added, a mixture of insoluble amines separated at once. With benzene and with benzyl chloride, the white precipitate

was found to contain the hydrochlorides of the amines only when the solutions had been exposed to sunlight, or after it stood for a long time. But, in all cases, if the solutions from which the precipitate had been removed were shaken with conc. hydrochloric acid, amines were found in the aqueous solution.

The properties of this intermediate compound present in the original solutions are illustrated in the work with benzene. It was found that it did not possess basic properties and was not easily hydrolyzed or reduced. When it was shaken with conc. hydrochloric acid, free chlorine was liberated and aniline derivatives were formed. This intermediate compound is probably an N-chloro-amine, *i. e.*, a chloro-amine in which the chlorine is combined with the nitrogen.

The work of Bender<sup>10</sup> is typical of that done by several investigators on the preparation and rearrangement of N-chloro-amines or substituted nitrogen chlorides. N-chloro-acetanilide was prepared from acetanilide and calcium hypochlorite. When heated to 172°, this compound rearranged to give *p*-chloro-acetanilide. In a study of the characteristic rearrangements of the substituted nitrogen halides, Chattaway and Orton<sup>11</sup> prepared a series of compounds in which the halogen of a chloro- or bromo-amine,  $C_6H_5NRX$ , rearranged successively to compounds with the halogen in positions 4, 2 and 6. The chloro-amine  $C_6H_5X_3NRX$ , which was finally obtained did not undergo further rearrangement.

The action of nitrogen trichloride on aniline, on methyl aniline and on dimethyl aniline has been studied by Hentschel.<sup>12</sup> When equimolecular parts of aniline and a solution of nitrogen trichloride in benzene react, trichloro-aniline is formed. This compound may also be formed by passing chlorine into a suspension of aniline hydrochloride in benzene. Methyl aniline similarly gives trichloro-methylaniline. Dimethyl aniline gives a product the structure of which was not determined.

Beilstein and Kurbatow<sup>13</sup> have prepared trichloro-aniline and tetrachloro-aniline by chlorination of mono and dichloro-aniline. Pentachloro-aniline has been prepared by Langer<sup>14</sup> by passing chlorine into an ether solution of dichloro-aniline.

Without introducing the question of positive and negative valence, it may be suggested as a possible explanation of the mechanism of the formation of the amines that the nitrogen trichloride adds to the benzene ring to give a compound,  $C_6H_5NCl_2.Cl$ . This may be followed by the loss of hydrochloric acid to give a chloro-amine,  $C_6H_5NCl_2$ . A possible explanation of the transformation produced by conc. hydrochloric acid may be the following. One molecule of hydrochloric acid adds to the nitrogen and is followed by the loss of a molecule of chlorine. This would leave an N-monochloro-amine which by a similar process is changed to the true amine.

<sup>10</sup> Bender, *Ber.*, 19, 2272 (1886).

<sup>11</sup> Chattaway and Orton, *Ber.*, 32, 3572 (1899).

<sup>12</sup> Hentschel, *Ber.*, 30, 2643 (1897).

<sup>13</sup> Beilstein and Kurbatow, *Ann.*, 196, 230 (1879).

<sup>14</sup> Langer, *ibid.*, 217, 120 (1882).

One of us<sup>15</sup> has shown that nitrogen trichloride and hydrochloric acid yield ammonium chloride and chlorine quantitatively, even in the absence of water. A similar explanation of the mechanism of the reaction was given.

The amines were extracted with ether after the addition of alkali to the aqueous solutions, and subsequently studied. From the method of formation and the presence of an excess of chlorine in the solutions a mixture of chlorinated amines was to be expected. This proved to be the case, the products evidently consisting of mixtures of chlorinated anilines and toluidines, respectively. These products when first obtained by evaporation of the ether from a dry ether solution, were viscous liquids. In the case of the product from benzene, a crystalline substance was obtained by recrystallization from ether and ligroin. The toluene product behaved quite peculiarly in that, on standing a few days, it changed to a dark brittle rosin-like solid. The amine mixture obtained from benzene did not do this. If chlorine had substituted in the side chain of the toluene molecule, such a change could be explained by a reaction between the chlorine of one molecule and the amino group of another. With this in mind, the action of nitrogen trichloride on benzyl chloride was tried. The viscous liquid mixture of amines obtained from this reaction solidified in a few days as that from toluene had done. The explanation given then seems probable.

### Experimental.

**I. Nitrogen Trichloride and Ethyl Chloride.**—Various methods for the preparation of nitrogen trichloride were tried. The method which was most satisfactory and the one finally used was the following. A solution of ammonium sulfate or ammonium nitrate, together with a suitable solvent for the nitrogen trichloride (in this case ethyl chloride itself was used), was surrounded with a freezing mixture at  $-10^\circ$  to  $-20^\circ$ , and the chlorine was passed into this solution at the rate of 0.2 to 0.4 g. per minute. The solutions were kept in intimate contact by means of a stirrer operated by a small motor. When the reaction was complete, the ethyl chloride solution was separated from the aqueous layer and dried with calcium chloride. Samples were taken and the remainder of the solution was sealed in thick-walled glass tubes and left in the dark for from 10 to 20 days.

<sup>15</sup> Noyes, *THIS JOURNAL*, **42**, 2173 (1920).

In the analysis of the solutions, the nitrogen was determined with conc. hydrochloric acid, according to the reaction  $\text{NCl}_3 + 4 \text{HCl} = \text{NH}_4\text{Cl} + 3 \text{Cl}_2$ , a method developed by one of us<sup>16</sup> and found to give better results than the usual sodium sulfite reduction. The ammonia was then determined by distillation from an alkaline solution. The chlorine was determined in another sample by Volhard's method, after it was reduced with sodium sulfite and treated with just enough potassium permanganate to oxidize the excess of sulfite.

In all, 1105 g. of solution containing 504.4 mg. atoms of nitrogen was prepared and used. From this amount the high-boiling residue formed in the reaction, on careful fractionation, gave the following fractions.

TABLE I.  
FRACTIONATION OF HIGH-BOILING RESIDUE.

Temp. ° C.	Vol. Cc.	Temp. ° C.	Vol. Cc.
50-58	0.25	81-84	1.00
58-62	0.50	84-150	0.20
62-72	0.40	150-175	0.50
72-76	0.20	175-190	2.00
76-81	0.25	Residue above 190°, 0.70	

Several of the usual methods for distinguishing between ethylene chloride and ethylidene chloride were tried with the known substances, but with the very small amounts with which it was necessary to work in the case of the fractions obtained above, none of these was found to be satisfactory. Finally a method of differentiation was developed in which very small quantities could be used. This was based on the rates of hydrolysis of the two chlorides by alkali, followed by oxidation of the product of hydrolysis with alkaline permanganate and the determination of the oxalate formed by titration with standard permanganate in hot acid solution. Ethylidene chloride was found to hydrolyze more rapidly than ethylene chloride and to give very much less oxalate on oxidation. The titration for 0.2 cc. each of ethylene and ethylidene chloride took 20.08 cc. and 3.05 cc. of standard permanganate solution respectively. The fractions of the chlorinated product corresponding to the boiling points of ethylene and ethylidene chloride behaved in every way like those of the known substances. The 81-84° fractions required 18.00 cc. of permanganate solution for oxidation of the oxalate formed, the 58-62° fraction, 3.90 cc. only.

**II. Nitrogen Trichloride with Toluene and with Benzyl Chloride.**—The solutions of the trichloride in toluene and the other aromatic liquids were prepared in much the same way as those in ethyl chloride had been. Five solutions in toluene were prepared totaling 1706 g. of solution and containing 921.7 mg. atoms of nitrogen and 2633.5 mg. atoms of chlorine. The ratio of chlorine to nitrogen is 2.85. After preparation the solutions gradually became opalescent and in the course of 5 or 6 hours, quite warm. In 12 to 15 hours the reaction was evidently complete, unless the solution had been kept cool. In that case, 3 or 4 days were required. The white precipitate which formed in the toluene solution was found to be a mixture of ammonium chloride and the hydrochloride of the amines. From a solution containing 114 mg. atoms of nitrogen, about 1 g. of free amine was found in the white precipitate and about an equal amount was secured from the toluene solution by treatment with conc. hydrochloric acid. Thus, only a small percentage of the total nitrogen present in the original solution was found in the amines. Of the remainder, about  $\frac{3}{4}$  was evolved as free nitrogen and  $\frac{1}{4}$  formed ammonium chloride. The toluene solution from the 5 preparations was found to contain 8 to 10 g. of the monochloro-toluenes, and 10 to 12 g. of benzyl chloride, with a

<sup>16</sup> Noyes, *THIS JOURNAL*, **42**, 2178 (1920).

large residue boiling above  $190^{\circ}$ . These fractions were identified by boiling point and other properties.

In the study of the amines some of the tests made were the following. By the sodium-fusion method the substance was found to contain nitrogen and chlorine. When a sample was diazotized and mixed with an alkaline solution of  $\beta$ -naphthol, a bright reddish-yellow precipitate was formed. Carbon dioxide was passed into a dry ether solution, but no amine carbonate was precipitated, proving the absence of benzyl amine,  $C_6H_5CH_2NH_2$ . The isocyanide test indicated the presence of a primary amine. The reaction with benzene sulfonyl chloride also showed this. When some of the free amine product was boiled with ammonium hydroxide, chlorine was found to be present in the solution. When the liquid mixture of the free amines stood for a few days, it slowly changed to a hard, brittle solid.

When dry hydrogen chloride was passed into an anhydrous ether solution of the amines the hydrochlorides were readily formed as a white precipitate. The molecular weight was determined by solution in dil. nitric acid and precipitation of the chloride as silver chloride. Assuming the presence of only one amino group in the molecule this gave a molecular weight of 273.5. A nitrogen determination of the hydrochloride by the absolute method gave 5.04% of nitrogen. This agrees quite closely with the theory that the molecule contains but one amino group. The hydrochloride of tetrachloro-toluidine contains 4.98% of nitrogen; that of trichloro-toluidine 5.69%.

Calc. for  $C_7H_7Cl_4NH_2HCl$ : Cl, 63.1; Calc. for  $C_7H_5Cl_3NH_2HCl$ : Cl, 57.5. Found: Cl, 59.0.

The only important features of the work with benzyl chloride were the following. The reaction occurred much more slowly. No amine was found in the white precipitate, unless the solution had been exposed to sunlight, or allowed to stand a long time. The viscous liquid product gradually solidified as that from toluene had done.

**III. Nitrogen Trichloride and Benzene.**—The solutions were prepared in the usual way. This reaction took place much more slowly than did the reaction with toluene. The main chlorination product was benzene hexachloride. The white precipitate contained no amine, unless the solution was allowed to stand a long time or had been exposed to sunlight. The benzene solution from which the precipitate had been removed was shaken with enough sodium sulfite solution to remove any free chlorine. No amine, or at most only a trace, was found in the sulfite solution. The benzene solution did not now have the yellow color of free chlorine, nor did it liberate iodine from potassium iodide readily, as a solution of chlorine would, but only on prolonged shaking. This nearly colorless benzene solution was then shaken with conc. hydrochloric acid. The benzene turned yellow and readily liberated iodine from potassium iodide, and the aqueous layer was found to contain the amines. It was found that the benzene solution of this N-chloro-amine could be concentrated by vacuum distillation.

The amount of the amine mixture obtained was about the same as that from toluene. Most of the tests made with the amines from toluene were carried out with this product. A mixture of chloro-anilines was indicated. The viscous liquid mixture of the free amines did not solidify on standing; but on treatment with ether and ligroin gave a crystalline product. The hydrochloride was made by passing dry hydrogen chloride into an anhydrous ether solution. A molecular weight determination with this material gave 287. The molecular weight of the hydrochloride of tetrachloro-aniline is 287.5, and of pentachloro-aniline, 303.

### Summary.

1. Nitrogen trichloride reacts with ethyl chloride to give, among other products, ethylene chloride. This compound is not a normal product of

the action of free chlorine on ethyl chloride in the absence of a catalytic agent.

2. Nitrogen trichloride with toluene forms benzyl chloride and the monochloro-toluenes together with higher chlorinated derivatives.

3. With benzene the main chlorination product is benzene hexachloride.

4. With toluene, with benzene, and with benzyl chloride, nitrogen trichloride forms small amounts of N-chloro-amines.

5. The N-chloro-amine group of the compounds formed from toluene and benzyl chloride is located in the nucleus and not in the side chain.

6. The chloro-amines at first formed are acted upon further by the nitrogen trichloride, or by chlorine, to give chlorinated chloro-amines. From benzene, the ultimate product is probably C-pentachloro-N-dichloro-aniline  $C_6Cl_5NCl_2$  but such a compound was not isolated.

7. The chlorinations referred to take place at ordinary temperatures, and consequently are different from the rearrangements of chloro-amines studied by Chattaway and Orton.<sup>11</sup> In this regard and also because all of the hydrogen atoms of the benzene nucleus may be replaced by chlorine, they resemble the chlorination of aniline hydrochloride by chlorine.<sup>14</sup>

8. The C-chloro-N-chloro-aniline liberates chlorine on treatment with conc. hydrochloric acid and is converted to C-chloro-aniline.

9. The facts established are most easily explained by assuming that the reactions are represented by the following equations.

10. The free chlorine from the last reaction would then chlorinate the chloro-amine.

11. The formation of hydrochloric acid under 9 involves a change of positive chlorine to negative, and the formation of considerable quantities of free nitrogen may be connected with this change.

## 7-CHLORO-7,12-DIHYDRO- $\gamma$ -BENZO-PHENARSAZIN AND SOME OF ITS DERIVATIVES.<sup>1</sup>

By W. LEE LEWIS AND C. S. HAMILTON.

Received June 27, 1921.

Of the nuclear heterocyclic arsenic compounds, that is, containing arsenic in the ring, those resulting from the condensation of arsenic chloride with diphenyl ether,<sup>2</sup> and with diphenylamine<sup>3</sup> together with their respective derivatives have been described. The German patent mentions the similar compounds formed with  $\beta,\beta$ -dinaphthylamine,  $p$ -ditolylamine,  $\alpha,\alpha$ -dinaphthylamine and  $p$ -oxy-diphenylamine, but the products or their derivatives are not described. Grüttner and Wiernik<sup>4</sup> prepared phenyl-arsino-pentamethylene and Grüttner and Krause<sup>5</sup> phenyl-arsino-tetramethylene. Of the heterocyclic arsenical compounds containing two nuclear arsenic atoms, arsanthren or diphenylene-diarsin and its derivatives have been prepared by Kalb.<sup>6</sup>

This investigation had for its purpose the preparation of additional compounds of this type, particularly those resulting from the condensation of arsenic trichloride with diphenyl methane, benzophenone, its oxime, diphenyl sulfide, diphenylhydrazine and phenyl- $\alpha$ -naphthylamine. Results were negative except with diphenyl-hydrazine which yielded 6-chloro-phenarsazin, and phenyl- $\alpha$ -naphthylamine which yields 7-chloro-7,12-dihydro- $\gamma$ -benzo-phenarsazin.

The hypothetical parent compound for the following derivatives would be  $\gamma$ -benzo-phenarsazin.

It is interesting to note that the 7-chloro derivative is much less irritating physiologically than the corresponding diphenyl-chloro-arsine,

<sup>1</sup> This work was done under a grant from the Interdepartmental Social Hygiene Board, Washington, D. C., Dr. T. A. Storey, Secretary. Some of the water-soluble products are being tested by Dr. A. S. Loevenhart of the University of Wisconsin, for their pharmaceutical value.

6-chloro-phenarsazin or 6-chloro-phenoxarzin. Moreover, it possesses to a marked degree the property, not shown by the others, of forming stable alkoxy derivatives of the type  $>As-OR$ .<sup>7</sup> The series of derivatives from methoxy to *n*-butoxy, not including the *iso*-propoxy which apparently forms with great difficulty, also the phenoxy and benzyloxy, are here described. These compounds are formed by adding in excess the respective alcohols treated with metallic sodium to a hot xylene solution of 7-chloro-7,12-dihydro- $\gamma$ -benzo-phenarsazin. The excess of sodium alcoholate and the resulting sodium chloride are removed by filtration and the filtrate concentrated to crystallization. The products are all recrystallizable from hot xylene, and have sharp melting points ranging from 209° to 152° (uncorr.). They are attacked by 10% sodium hydroxide solution setting free the alcohol. They are all soluble in carbon tetrachloride, glacial acetic acid and acetone which are good recrystallizing agents. An alcohol other than that corresponding to the alkoxy group present cannot be used for purification as replacement of the alkyl results. Similarly, attempted recrystallization of an alkoxy derivative with aqueous phenol gives the phenoxy compound.

### Experimental.

7-Chloro-7,12-dihydro- $\gamma$ -benzophenarsazin,  $HN \begin{matrix} \diagup C_{10}H_5 \\ \diagdown C_6H_4 \end{matrix} AsCl$ .—Eighty-eight g.

of phenyl- $\alpha$ -naphthylamine and 80 g. (10% excess) of redistilled arsenic trichloride were heated under a reflux condenser. The mixture commenced to boil at 165–170° with evolution of hydrogen chloride. The boiling temperature gradually rose to 200° when the evolution of hydrogen chloride had practically ceased. The time required to reach this temperature was about 2 hours. Upon cooling the reaction mixture solidified to a greenish-yellow mass. The yield of the crude product was 115 g., 87% of the calculated amount. The crude product was recrystallized from xylene and washed with alcohol. A second recrystallization from xylene yielded fine needles, canary-yellow in color and melting at 219° (uncorr.).

7-Chloro-7,12-dihydro- $\gamma$ -benzophenarsazin is insoluble in water and is not attacked by 6 *N* sodium hydroxide solution. It is soluble in xylene, glacial acetic acid, alcohol, benzene, and carbon tetrachloride, and has a slightly irritating effect on the mucous membranes of the nose and throat. The best solvent for recrystallization is xylene in which it is 5% soluble.

*Analyses.* Subs., 0.1995, 0.2018: 15.88, 16.20 cc. of 0.0765 *N* iodine sol. Calc. for  $C_{16}H_{11}NClAs$ : As, 22.90. Found: 22.83, 23.07.

7-Methoxy-7,12-dihydro- $\gamma$ -benzo-phenarsazin,  $HN \begin{matrix} \diagup C_{10}H_5 \\ \diagdown C_6H_4 \end{matrix} As-OCH_3$ .—Sodium

methylate, prepared by dissolving 1.4 g. of clean metallic sodium in 50 cc. of absolute methyl alcohol, was added to 9 g. of 7-chloro-7,12-dihydro- $\gamma$ -benzophenarsazin

<sup>7</sup> Cf. Michaelis, *Ann.*, 321, 143 (1902); Wieland and Rheinheimer, *Ann.*, 423, 1 (1921).

dissolved in 200 cc. of hot xylene. The mixture was heated under a reflux condenser for 10 minutes. The excess of sodium methylate and the sodium chloride produced in the reaction were filtered hot. Upon cooling, the filtrate remained clear. Approximately 100 cc. of xylene was removed by distillation under reduced pressure. On cooling, almost colorless crystals of the methoxy compound were deposited. This was recrystallized from xylene. The yield was 8 g. or 89%. The product melts at 209° (uncorr.) and is soluble in benzene, carbon tetrachloride, and acetone, but insoluble in water. It is decomposed by 10% sodium hydroxide.

*Analyses.* Subs., 0.2092, 0.2102: 24.54, 24.99 cc. of 0.0521 *N* iodine sol. Calc. for  $C_{17}H_{14}ONAs$ : As, 23.22. Found: 22.92, 23.23.

**7-Ethoxy-7,12-dihydro- $\gamma$ -benzo-phenarsazin**,  $HN \begin{array}{c} \diagup C_{10}H_6 \\ \diagdown C_6H_4 \end{array} AS - OC_2H_5$ .—This

compound was prepared in a similar manner, using sodium ethylate. The yield was 76%. The compound melts at 165° (uncorr.) and when recrystallized from absolute ethyl alcohol gives colorless crystals which turn slightly yellow on standing. It is soluble in the common organic solvents and is decomposed by a 10% sodium hydroxide solution.

*Analyses.* Subs., 0.2005, 0.1998: 22.60, 22.49 cc. of 0.0521 *N* iodine sol. Calc. for  $C_{18}H_{16}ONAs$ : As, 22.25. Found: 22.02, 21.99.

**7-*n*-Propoxy-7,12-dihydro- $\gamma$ -benzo-phenarsazin**,  $HN \begin{array}{c} \diagup C_{10}H_6 \\ \diagdown C_6H_4 \end{array} AS - OC_3H_7$ .—This

compound was obtained by treating 9 g. of 7-chloro-7,12-dihydro- $\gamma$ -benzophenarsazin with an excess of sodium *n*-propylate. A yield of 7.3 g. (74%) of pale yellow crystals resulted. The compound melts at 152° (uncorr.), is soluble in benzene, acetone and carbon tetrachloride, and is attacked by hot alkalis.

*Analyses.* Subs., 0.2023, 0.1970: 22.28, 21.52 cc. of 0.0521 *N* iodine sol. Calc. for  $C_{19}H_{18}ONAs$ : As, 21.36. Found: 21.52, 21.34.

**7-*n*-Butoxy-7,12-dihydro- $\gamma$ -benzo-phenarsazin**,  $HN \begin{array}{c} \diagup C_{10}H_6 \\ \diagdown C_6H_4 \end{array} AS - OC_4H_9$ .—This

compound was obtained by the action of an excess of sodium *n*-butylate on 9 g. of 7-chloro-7,12-dihydro- $\gamma$ -benzophenarsazin dissolved in 200 cc. of xylene. The yield was 6.7 g., or 67%. The almost colorless product is soluble in benzene, acetone and glacial acetic acid. It is decomposed by 10% sodium hydroxide solution. The compound softens slightly at 120° but does not melt completely even at 260°. The same results were obtained with samples prepared from crude *n*-butyl alcohol and the *c. p.* alcohol.

*Analyses.* Subs., 0.1997, 0.2002: 20.95, 20.93 cc. of 0.0521 *N* iodine sol. Calc. for  $C_{20}H_{20}ONAs$ : As, 20.54. Found: 20.49, 20.42.

**7-Phenoxy-7,12-dihydro- $\gamma$ -benzo-phenarsazin**,  $HN \begin{array}{c} \diagup C_{10}H_6 \\ \diagdown C_6H_4 \end{array} AS - OC_6H_5$ .—So-

dium phenolate was prepared by dissolving 1.4 g. of metallic sodium in a solution of 8 g. of phenol in 30 cc. of absolute ethyl ether. This was added to 9 g. of 7-chloro-7,12-dihydro- $\gamma$ -benzo-phenarsazin in 200 cc. of xylene, and the usual procedure followed. The compound was deposited in fine yellow needles. The yield was 6.5 g. or 61%. The product melts at 179° (uncorr.), is soluble in the common organic solvents, and readily attacked by a 10% solution of sodium hydroxide.

*Analyses.* Subs., 0.1973, 0.2021: 19.50, 20.03 cc. of 0.0521 *N* iodine sol. Calc. for  $C_{22}H_{16}ONAs$ : As, 19.48. Found: 19.31, 19.36.

By following the above procedure the compound was prepared by adding an excess of sodium benzoate to 9 g. of 7-chloro-7,12-dihydro- $\gamma$ -benzophenarsazin in xylene solution. A yield of 7.3 g., or 67% was obtained. The almost colorless compound melts at 154° (uncorr.). It is soluble in benzene, glacial acetic acid and carbon tetrachloride.

*Analyses.* Subs., 0.2042, 0.2119: 19.55, 20.32 cc. of 0.0521 *N* iodine sol. Calc. for  $\text{C}_{23}\text{H}_{18}\text{ONAs}$ : As, 18.72. Found: 18.70, 18.74.

7,12-dihydro- $\gamma$ -benzo-phenarsazin was dissolved in 800 cc. of glacial acetic acid. To this solution 100 g. of a 3% solution of hydrogen peroxide was added and the whole heated under a reflux condenser for 15 minutes. When the solution had cooled, the acid crystallized in almost colorless needles. The crude product was recrystallized from glacial acetic acid. The yield was 17 g., or 81% of the calculated amount.

The acid does not melt below 260°. It is insoluble in all the common organic solvents, with the exception of glacial acetic acid, and soluble in alkalis in the cold.

*Analyses.* Subs. (dried at 120° for 10 hrs.), 0.2117, 0.1986: 23.40, 22.11 cc. of 0.0521 *N* iodine sol. Calc. for  $\text{C}_{16}\text{H}_{14}\text{O}_3\text{NAs}$ : As, 21.86. Found: 21.59, 21.79.

When the acid is heated to constant weight at 150° it loses one molecule of water giving a form of the arsenic acid containing the more usual grouping  $>\text{As}(\text{O})\text{OH}$ .

*Analyses.* Subs. (heated to const. wt. at 150°), 0.2312, 0.2146: 31.72, 29.35 cc. of 0.0445 *N* iodine sol. Calc. for  $\text{C}_{16}\text{H}_{12}\text{O}_2\text{NAs}$ : As, 23.07. Found: 22.90, 22.83. Loss on heating at 150°. Subs., 0.4218, 0.4059: wt. lost, 0.0215, 0.0209. Calc. for 1  $\text{H}_2\text{O}$ : 5.24. Found: 5.09, 5.13.

The sodium salt of  $\gamma$ -benzo-phenazarsinic acid was prepared in the following manner. Five g. of  $\gamma$ -benzo-phenazarsinic acid was dissolved in a solution of 0.1 *N* sodium hydroxide. The solution was filtered and concentrated to a small volume on the steam-bath. Upon cooling, the sodium salt was deposited in needle-like crystals, pink in color. After several recrystallizations from 95% alcohol an almost colorless product was obtained. The yield was 5.2 g., or 85%. The sodium salt does not melt below 260°. It is soluble in water (5%), in alcohol and acetone and is quite hygroscopic. It is insoluble in benzene and xylene.

*Analyses.* Subs., 0.2013, 0.2209: 18.40, 19.95 cc. of 0.0521 *N* iodine sol. Calc. for  $\text{C}_{16}\text{H}_{11}\text{O}_2\text{NAsNa}\cdot 4\text{H}_2\text{O}$ : As, 17.89. Found: 17.86, 17.65.

7,12-Dihydro- $\gamma$ -benzo-phenarsazin-7-oxide,

—Five g. of 7-chloro-7,12-dihydro- $\gamma$ -benzo-phenarsazin was dissolved in 100 cc. of xylene, and to this was added a solution of 2 g. of freshly prepared silver oxide in 50 cc. of ammonium hydroxide. The slightly yellow oxide precipitated immediately. After heating under a reflux condenser for a few minutes the oxide was filtered hot and washed free from silver with ammonium hydroxide. The yield was 4 g., or 90%. The oxide does not darken or melt below 250°, is soluble in glacial acetic acid and insoluble in benzene, xylene, and carbon tetrachloride.

*Analyses.* Subs., 0.2011, 0.2005: 25.61, 25.49 cc. of 0.0521 *N* iodine sol. Calc. for  $C_{22}H_{22}ON_2As_2$ : As, 25.00. Found: 24.88, 24.84.

7-Bromo-7,12-dihydro- $\gamma$ -benzo-phenarsazin,  $HN \begin{array}{c} \diagup C_{10}H_8 \\ \diagdown C_6H_4 \end{array} As-Br$ .—Five g. of

7-phenoxy-7,12-dihydro- $\gamma$ -benzo-phenarsazin was heated under a reflux condenser for 4 hours with an excess of conc. hydrobromic acid. The green, crude product was recrystallized several times from xylene, yielding dark yellow needles. The yield was 3.6 g. or 75%. The crystals melt at 227° (uncorr.). The compound is soluble in benzene, toluene, xylene and glacial acetic acid. It is insoluble in water and is not acted upon by dilute alkalis.

*Analyses.* Subs., 0.1999, 0.1991: 20.41, 20.46 cc. of 0.0521 *N* iodine sol. Calc. for  $C_{16}H_{11}NBrAs$ : As, 20.16. Found: 19.95, 20.08.

7-Iodo-7,12-dihydro- $\gamma$ -benzo-phenarsazin,  $HN \begin{array}{c} \diagup C_{10}H_8 \\ \diagdown C_6H_4 \end{array} As-I$ .—Three g. of

7,12-dihydro-7-phenoxy- $\gamma$ -benzo-phenarsazin was refluxed for 4 hours with a solution of hydriodic acid made by adding 10 g. of conc. hydriodic acid to 90 cc. of distilled water. The crude product was dark red in color. Upon recrystallization from xylene, beautiful red needles were obtained. The yield was 2.5 g. or 62%. This compound was also prepared in the above manner by heating 7,12-dihydro- $\gamma$ -benzo-phenarsazin-7-oxide with hydriodic acid. The compound melts at 205° (uncorr.), is soluble in benzene, xylene, toluene and glacial acetic acid.

*Analyses.* Subs., 0.2043, 0.1953: 22.15, 21.35 cc. of 0.0445 *N* iodine sol. Calc. for  $C_{16}H_{11}NIAs$ : As, 17.90. Found: 18.10, 18.24.

7,12-Dihydro- $\gamma$ -benzo-phenarsazin-7-sulfide,

—Three g. of 7-chloro-7,12-dihydro- $\gamma$ -benzo-phenarsazin was dissolved in 500 cc. of absolute ethyl alcohol and hydrogen sulfide bubbled through the solution. A yellow precipitate was formed immediately. As it was insoluble in all common organic solvents the impurities were removed by refluxing with xylene. The yield was 2 g., or 71%. The compound melts at 204–5° (uncorr.).

*Analyses.* Subs., 0.1980, 0.2001: 25.61 26.03 cc. of 0.0497 *N* iodine sol. Calc. for  $C_{22}H_{22}N_2As_2S$ : As, 24.35. Found: 24.12. 24.26.

### Condensation of Diphenylhydrazine and Arsenic Trichloride.

Ten g. of diphenylhydrazine was treated with 12 g. of arsenic trichloride which had been cooled to 5°, and the mixture gently warmed under a reflux condenser. At 34° the reaction became violent and the temperature rose at once to 105°. The mixture began to boil at 130–135° and in the course of 2 hours the boiling temperature rose to 210°, when yellowish vapors appeared in the flask. Upon cooling the reaction mixture solidified to a black granular mass. Recrystallization from xylene gave 8.5 g. of greenish-yellow crystals. Upon recrystallization from carbon tetrachloride fine yellow needles, melting at 192° (uncorr.), were obtained. The compound has the properties and composition of 6-chloro-phenarsazin.

The formation of this compound may be explained by the fact that diphenylhydrazine, at its boiling point, decomposes in part to form diphenylamine and other products.<sup>8</sup> Part of the arsenic chloride, in all probability, acts as a reducing agent and hastens the reaction at a lower temperature. The diphenylamine thus formed then condenses with arsenic trichloride to form 6-chloro-phenarsazin.

Subs., 0.2030, 0.2200: 30.80, 33.30 cc. of 0.0479 *N* iodine sol. Calc. for  $C_{12}H_9NAsCl$ : As, 27.02. Found: 27.29, 27.23.

Subs., 0.4053, 0.4207: 13.98, 13.94 cc. of 0.1 *N* HCl. Calc. for  $C_{12}H_9NAsCl$ : *N*, 5.04. Found: 4.83, 4.85.

### Summary.

1. A brief summary of the chemistry of the nuclear heterocyclic arsenic compounds is presented.

2. The condensation of phenyl- $\alpha$ -naphthylamine with arsenic chloride, and the properties of the resulting 7-chloro-7,12-dihydro- $\gamma$ -benzo-phenarsazin are described.

3. The methods of preparation and the properties of the following derivatives of 7-chloro-7,12-dihydro- $\gamma$ -benzo-phenarsazin are given: 7-methoxy-7,12-dihydro- $\gamma$ -benzo-phenarsazin; 7-ethoxy-7,12-dihydro- $\gamma$ -benzo-phenarsazin; 7-*n*-propoxy-7,12-dihydro- $\gamma$ -benzo-phenarsazin; 7-*n*-butoxy-7,12-dihydro- $\gamma$ -benzo-phenarsazin; 7-phenoxy-7,12-dihydro- $\gamma$ -benzo-phenarsazin; 7-benzyloxy-7,12-dihydro- $\gamma$ -benzo-phenarsazin;  $\gamma$ -benzo-phenaz-arsinic acid; 7,12-dihydro- $\gamma$ -benzo-phenarsazin-7-oxide; 7-bromo-7,12-dihydro- $\gamma$ -benzo-phenarsazin; and 7,12-dihydro- $\gamma$ -benzo-phenarsazin-7-sulfide.

 **$\beta,\beta'$ -DICHLORO-DIETHYL ETHER. THE OXYGEN ANALOG OF  
MUSTARD GAS.<sup>1</sup>**

BY OLIVER KAMM AND JOHN H. WALDO.

Received June 27, 1921.

The simple analog of mustard gas in which the sulfur atom has been replaced by oxygen apparently has not been described in the literature. We were therefore interested in studying this compound, not merely in order to compare its physiological action with that of its deadly relative, but also with a view aiming at the possible use of the compound as a new reagent in organic synthesis, particularly in the preparation of cyclic derivatives containing the polymethylene oxide structure.

<sup>8</sup> Stahel, *Ann.*, 258, 244 (1890).

<sup>1</sup> Presented at the St. Louis Meeting of the American Chemical Society, March 1920.

It is not feasible to prepare  $\beta,\beta'$ -dichloro-diethyl ether by the chlorination of ethyl ether for the reason that such a reaction leads to the production of mixtures containing mainly *alpha* chlorination products; it may be prepared conveniently, however, by the general method for the preparation of ethers, *viz.*, by the dehydration of two molecules of the corresponding chloro alcohol. Since the sulfur analog can be prepared readily by the action of sulfur chloride upon ethylene, there is suggested also the possibility of obtaining the oxygen derivative by an analogous reaction:

We are indebted to Dr. W. J. Hale, of the Dow Chemical Company for the information that a reaction similar to that expressed by the above equation actually takes place during the manufacture of ethylene chlorohydrin, and that a product identical in physical properties with the ether now characterized by us may be isolated from crude ethylene chlorohydrin.

In addition to the usual analysis, the dichloro-ether has been identified by its condensation with aniline, a reaction which yields an oxazine of known structure, 4-phenyl-morpholin. Because this derivative is a solid, it is well suited for identification purposes. By a slight modification of the usual tautomeric ester synthesis, the dichloro-ether (I) has been condensed with malonic ester to yield 4,4-dicarboxy-ethyl-pentamethylene oxide (II).

This malonic ester derivative should condense readily with urea to yield a new *spiro* derivative of an unusual type, one ring consisting of a pyrimidine and the other of a cyclic oxide structure. This condensation occurs readily. The resultant barbituric acid derivative (III) is closely related in structure to the well-known hypnotic, barbital (IV).

It will be noted that the new compound differs from barbital (veronal) only in the fact that an oxygen atom may be considered as having replaced one hydrogen atom from each of the two methyl groups. The observations made in respect to the difference in physiological action between these two barbituric acid derivatives ultimately should prove of aid in the interpretation of the underlying principles concerning the action of such drugs in the animal body.

### Experimental Part.

**$\beta,\beta'$ -Dichloro-diethyl Ether.**—This compound was prepared by the action of conc. sulfuric acid upon ethylene chlorohydrin. When, by direct analogy, the usual continuous method for the preparation of ethyl ether, was employed, a very poor, almost negligible, yield was obtained. When the alcohol was refluxed with  $\frac{1}{5}$  its weight of conc. sulfuric acid, followed subsequently by direct distillation, the yield was 10% to 15% of the desired product. A further modification of the method consisted in the gradual removal of water during the period of refluxing, this resulted in a yield of about 20% to 25%. Based upon the amount of chlorohydrin actually lost in the process, the yield amounted to about 75%.

A mixture of 200 g. of ethylene chlorohydrin and 35 g. of conc. sulfuric acid was placed in a round-bottom boiling flask and heated under a reflux condenser for 6 hours. During this refluxing period, the water in the condenser was maintained at 90° to 100° and the heating regulated so that a very slow but continuous removal of water and chlorohydrin was effected. This distillate consisted mainly of the constant-boiling mixture of the alcohol and water,<sup>2</sup> and was saved, together with the subsequent distillate, for recovery of chlorohydrin. About  $\frac{1}{2}$  the volume of the reaction mixture was removed during the refluxing period, after which the liquid was distilled directly through a horizontal condenser. This distillation, in spite of the formation of sulfur dioxide, was continued until only a charred mass remained in the fractionating flask. The distillate was washed with sodium carbonate solution, dried with sodium sulfate, and then subjected to careful fractionation, with the aid of an efficient column.

The  $\beta,\beta'$ -dichloro-diethyl ether is a colorless oil with a pleasant ethereal odor; b. p., 177–8° (corr.);  $d_{20}^{20}$ , 1.213;  $n_{20}^{20}$ , 1.457.

**Analysis.** Subs., 0.2417, 0.1910: 33.24 cc., 26.27 cc. of 0.1 *N* AgNO<sub>3</sub>. Calc. for C<sub>4</sub>H<sub>8</sub>OCl<sub>2</sub>: Cl, 49.6. Found: 48.8, 48.8.

**4-Phenyl-morpholin.**—A mixture of 72 g. of the dichloro ether and 47 g. of aniline was heated for about 10 hours under a reflux condenser with sufficient 10% aqueous sodium hydroxide to remove the hydrochloric acid liberated in the reaction. The oily reaction product was extracted with ether and the solvent layer washed with several small portions of 1% hydrochloric acid in order to remove those impurities more basic than the desired oxazine. Upon evaporation of the ether, an oily mass of crystals remained, from which the residual oil was removed by pressing the crystals on a porous clay plate. The remaining solid was then crystallized from 50% aqueous alcohol and obtained in the form of almost white flakes melting at 57° to 58°. Upon distillation, a pure white product was obtained boiling at 259° to 260°, at 745 mm. These constants, together with the chlorine analyses recorded above, establish the constitution of the dichloro-diethyl ether.

**4,4-Dicarboxyethyl-tetrahydro-pyran.**—One-half mole of sodium was dissolved in 200 cc. of absolute ethyl alcohol. To the sodium ethylate solution,  $\frac{1}{2}$  mole of malonic ester and 72 g. ( $\frac{1}{2}$  mole) of the dichloro-diethyl ether were added, and the mixture was refluxed on the water-bath for an hour. The flask containing the reaction mixture was then cooled, an alcoholic solution of a second  $\frac{1}{2}$  mole of sodium ethylate added, and the mixture was refluxed again during an hour. After cooling the reaction mixture, the sodium chloride was separated by filtration, the major portion of the alcohol removed by distillation, and the remaining product treated with water. The oil which separated was extracted with ether. The ether solution was dried over anhydrous sodium sulfate and subjected to distillation with the use of a short but fairly efficient fractionating column. Yield 30 g. (26%).

<sup>2</sup> THIS JOURNAL, 41, 1422 (1919).

The 4,4-dicarboxyethyl-tetrahydro-pyran is a liquid boiling at  $260^{\circ}$  (740–745 mm.);  $d_{20}^{20}$ , 1.107. It was not subjected to analysis, but its condensation product with urea served for its analytical identification. Its physical and chemical properties agree with the assigned formula (II).

In one experiment, the above directions were modified and the total quantity of sodium ethylate was used at one time. This variation resulted in the formation of an appreciable quantity of a higher-boiling product consisting partly, no doubt, of the ethoxy derivative,  $C_2H_5-O-CH_2-CH_2-O-CH_2-CH_2-CH < (C(O)OC_2H_5)_2$ .

**Tetrahydro-pyran-4,5-spiro-2,4,6-triketo-hexahydro-pyrimidine.**<sup>3</sup>—This barbituric acid derivative was prepared by the well-known condensation of malonic ester derivatives with urea in the presence of sodium ethylate.

A 2.5 g. portion of sodium was dissolved in 35 cc. of absolute ethyl alcohol. This sodium ethylate solution, together with 10 g. of 4,4-dicarboxyethyl-tetrahydro-pyran and 3.3 g. of finely powdered urea, was heated in a sealed tube for 5 hours at  $100^{\circ}$  to  $105^{\circ}$ . The reaction mixture was then filtered, the mass of sodium salts treated with dil. hydrochloric acid, and the insoluble barbituric acid derivative separated by filtration. The product was purified by crystallization from hot water. Yield, 41%.

This barbituric acid derivative is a white crystalline product melting at  $218^{\circ}$ . It crystallizes with one molecule of water which, however, is gradually lost if it is dried at  $110^{\circ}$ , as may be seen from the following data.

Subs., 0.6170: heated at  $110^{\circ}$ . Calc. loss, 0.0510; Found: 0.0514. Loss in weight with time: 1st. hour, 0.0302; 2nd. hour, 0.0206; 3rd. hour, 0.0004; 4th. hour, 0.0002.

Subs., 0.2336:  $H_2O$ , 0.1148;  $CO_2$ , 0.3767. Calc. for  $C_8H_{10}O_4N_2 \cdot H_2O$ : C, 44.4; H, 5.60; N, 12.96. Found: C, 43.9; H, 5.49; N, 12.9.

### Physiological Behavior of $\beta, \beta'$ -Dichloro-diethyl Ether and of Tetrahydro-pyran-4,5-spiro-2,4,6-triketo-hexahydro-pyrimidine.

The explanation appears to be generally accepted that  $\beta, \beta'$ -dichloro-diethyl sulfide exerts its highly toxic influence upon the tissues because of the liberation of hydrochloric acid within the body cells. The physical properties of the compound are apparently such as to yield exactly the requisite relationship between the rate of penetration of the compound and its rate of hydrolysis to produce the well-known toxic effect. It was therefore of interest to test the corresponding oxygen ether for the possibility of a related effect; it was found, however, that  $\beta, \beta'$ -dichloro-diethyl ether exerted no similar deleterious action upon the tissues; in fact, liberal quantities of the ether were applied directly to the skin without a noticeable effect.

The close structural relationship between the well-known hypnotic, barbital, and the new barbituric acid derivative, tetrahydro-pyran-4,5 *spiro*-2,4,6-triketo-hexahydro-pyrimidine, has been briefly referred to above. The *spiro* compound was found to possess no hypnotic and no toxic effect when administered orally to a rabbit of about 1.5 kg. weight in

<sup>3</sup> This system of nomenclature has been proposed recently by Dox and Yoder, *THIS JOURNAL*, 43, 678 (1921). The numerals preceding the word *spiro* mean that the *spiro* carbon corresponds to Position 4 in the pyran ring and Position 5 in the pyrimidine ring.

lg. doses. Barbitol, on the other hand, is effective<sup>4</sup> even in considerably smaller amounts, the fatal dose for rabbits being about 0.35 g. per kg. body weight.

The above difference in physiological effect is unusual for the reason that di-alkyl derivatives of barbituric acid are practically all effective unless, of course, the alkyl groups are sufficiently high in molecular weight, as in the dibenzyl compound, to produce compounds of limited solubility. The new derivative, in which we may consider that the two alkyl groups have been united through an oxygen atom, does not differ greatly from barbitol in its physical properties; therefore one must seek elsewhere an explanation for its lack of activity.

The observation that the new derivative is in combination with water to form a monohydrate suggests one possible explanation for its non-activity, particularly so, since barbitol does not crystallize as a hydrate under similar experimental conditions. We are inclined, however, to a different explanation.

It is known that when barbitol is administered to an animal a considerable percentage of the drug is eliminated unchanged. The *spiro* derivative appeared, however, in the urine in the form of fine needles melting in the neighborhood of 150° to 160°. Unfortunately, because of the limited physiological study, we neglected to seek an identification of the transformation product as eliminated from the animal body. There is a possibility that in this instance, because of the *spiro* structure, the compound is more susceptible to hydrolysis *in vivo*. Whether or not this view is correct may be determined when reports are available concerning the physiological behavior of related cyclic derivatives.

### Summary.

1.  $\beta,\beta'$ -Dichloro-diethyl ether has been prepared by the dehydration of ethylene chlorohydrin.

2. The new dichloro ether was condensed with malonic ester and yielded 4,4-dicarboxyethyl-tetrahydro-pyran. This di-substituted malonic ester derivative was condensed with carbamide and yielded a substituted barbituric acid of the *spiro* type.

3.  $\beta,\beta'$ -Dichloro-diethyl ether possesses no baneful effect upon the tissues of the animal body, an action which is so striking in the case of the sulfur analog known as *mustard gas*.

4. Tetrahydro-pyran 4,5-*spiro*-2,4,6-triketo-hexahydro-pyrimidine, although closely related in structure to barbitol, possesses no marked hypnotic properties. In contrast to the latter compound, it is modified within the animal body. The ready formation of an inert hydrolytic product probably accounts for its physiological behavior.

 $\gamma, \gamma'$ -DIHALOGENO-DIPROPYL ETHERS.

BY OLIVER KAMM AND WALTER H. NEWCOMB.

Received June 27, 1921.

The present work was undertaken in order to prepare the symmetrical  $\gamma$ -dichloro and dibromo substitution products of dipropyl ether, compounds which may prove of value in the synthesis of certain heterocyclic derivatives containing rings of more than 6 atoms. By analogy to the preparation of  $\beta, \beta'$ -dichloro-diethyl ether described in the preceding paper, the derivatives of dipropyl ether were prepared by subjecting trimethylene-chloro- and bromohydrins to dehydration.

Trimethylene bromide is readily prepared from the corresponding glycol, even with aqueous hydrobromic acid. The presence of sulfuric acid increases the yield.<sup>1</sup> Accordingly an attempt was made to prepare the bromohydrin by an analogous reaction. Since trimethylene glycol is practically non-volatile with water vapor while the bromohydrin is appreciably volatile, the latter compound may be continuously removed from the reaction mixture, a procedure which should tend to favor Reaction I at the expense of Reaction II.

Unfortunately, the reaction velocity of the step illustrated by Equation II is far greater than that of Step I, and consequently in spite of the use of a considerable excess of trimethylene glycol, the dibromide represents the largest percentage of the yield. Simultaneously with the formation of the first two products a third reaction takes place as represented by Equation III. The desired dibromo ether may therefore be isolated during the preparation of the bromohydrin.

Preliminary experiments have been conducted in the endeavor to convert  $\gamma, \gamma'$ -dibromo-dipropyl ether into hexamethylene oxide by the removal of the bromine atoms by means of metals. These reactions, however, have yielded products contaminated with di-allyl ether and dipropyl ether, together with products which are probably mixed ethers, and we are unable at present to offer a feasible method for the preparation of this unknown cyclic ether.

## Experimental Part.

Trimethylene chlorohydrin was prepared with aqueous hydrochloric acid, in a manner analogous to that described (p. 2229) for the preparation of the bromohydrin. In view of the fact that an improved method has

<sup>1</sup> THIS JOURNAL, 42, 301 (1920).

recently been contributed from the Eastman Laboratory<sup>2</sup> we omit a discussion of our own results.

$\gamma,\gamma'$ -Dichloro-dipropyl ether was obtained in 10–15% yield by refluxing trimethylene chlorohydrin with 20% of its weight of sulfuric acid. The ether is a colorless oil boiling at 215° at 745 mm.,  $d_{20}^{20}$  1.140.

**Preparation of Trimethylene Bromohydrin and of  $\gamma,\gamma'$ -Dibromo-dipropyl Ether.**

To 3 moles of trimethylene glycol in a 1-liter distilling flask add 1 mole of sulfuric acid and  $1\frac{1}{2}$  moles of hydrobromic acid in the form of the aqueous 48% solution. This mixture is distilled until the distillate is equal in volume to the hydrobromic acid solution added. 1 mole of the glycol and 1 mole of hydrobromic acid are added and the distillation repeated until the volume of the distillate is again equal to the volume of the hydrobromic acid solution added. The molar additions of hydrobromic acid and of the glycol and the distillations may be repeated as many times as may be desired. The halogen derivatives of the glycol distil over with water and the distillate separates into two layers. At the end of the distillation, which is finally carried to the stage at which considerable charring takes place, the distillate is neutralized with sodium carbonate and the two layers separated. The oily layer containing the organic derivatives is dried over anhydrous sodium sulfate. The aqueous layer is extracted with ether in order to remove any of the bromohydrin which is dissolved therein, and the ether extract is also dried with anhydrous sodium sulfate. The ether is distilled leaving the nearly pure bromohydrin which is subjected to fractional distillation. The main product is distilled until a temperature of 170° is reached, in order to remove most of the trimethylene bromide, and the remaining residue is distilled under diminished pressure. By means of a careful refractionation with the use of a column, a separation of the trimethylene bromide from the trimethylene bromohydrin may be attained.

The separation of the bromohydrin from the dibromo-dipropyl ether which is also formed in the reaction can be easily accomplished because of the wide difference between the boiling points of the two products. The yield of the derivatives depends somewhat on the number of additions of glycol and hydrobromic acid. The increase in the number of additions decreases the yield of the dibromide and increases the yield of the bromohydrin and of the dibromoether. A limit to the number of additions, however, is reached because of the charring of the reaction mixture.

The following table gives the average yields of several runs by the above process. The percentage yields are calculated on the possible theoretical yield for each substance based upon the amount of hydrobromic acid used. 85 to 95% of this amount is accounted for in the combined yields.

No. of extra additions of HBr and glycol.	Glycol used G.	HBr used G.	Yield of dibromide.	Yield of bromohydrin.	Grams of dibromo ether.
2	380	283.5	214 g. 60%	86 g. 17%	48 g. 10.7%
5	608	526.5	372.5 g. 57%	210.5 g. 23%	126.7 g. 15%

The dibromo-dipropyl ether is a colorless liquid which undergoes slight decomposition when distilled under ordinary pressure. It boils at 128° at 19 mm.;  $d_{20}^{20}$  1.574. As might be expected from its structure, this ether is insoluble in water, but is soluble in the common organic solvents; it is also appreciably volatile with water vapor. In solubility and volatility, dichloro-ethers derived from ethylene- and trimethylene chlorohydrins, show a close resemblance to dibromo-dipropyl ether.

<sup>2</sup> THIS JOURNAL, 43, 369 (1921).

*Analysis.* Subs., 0.2030, 0.1716; AgBr, 0.2902, 0.2456. Calc. for  $C_6H_{12}OBr_2$ : Br, 61.5. Found: 60.8. 60.9.

### Summary.

$\gamma, \gamma'$ -Dichloro- and dibromo-dipropyl ethers have been prepared and their physical properties recorded.

## THE ACTION OF AMMONIA WATER ON DICYANDIAMIDE.<sup>1</sup>

BY TENNEY L. DAVIS.

Received July 1, 1921.

Dicyandiamide hydrolyzed with sulfuric acid produces one molecule of guanidine sulfate and one of ammonium sulfate, and guanidine sulfate may be obtained in satisfactory yields by this process.<sup>2</sup> But dicyandiamide is most readily prepared from Lime-nitrogen, from which ammonia may be produced more readily by simpler methods—and the production of ammonia from dicyandiamide in a process where guanidine is the object might well be regarded as the virtual loss of one quarter of the nitrogen which has earlier been "fixed" in the form of Lime-nitrogen and of dicyandiamide. We<sup>1</sup> have studied the reaction of ammonia on dicyandiamide with the expectation that it would lead to the formation of guanidine or of guanidine carbonate without the agency of mineral acid, and in the hope that it might perhaps lead to the formation of two molecules of guanidine from one of dicyandiamide.

We find that the action of ammonia water on dicyandiamide when the materials are heated together in a sealed tube is simple hydrolysis, water only being effectively involved and the dicyandiamide being converted first into guanylurea and later into guanidine carbonate. We have followed the progress of the reaction by precipitating the solution with ammonium picrate and have been able to judge from the melting point whether the precipitate consisted of picrate of guanidine or of picrate of guanylurea. After relatively short durations of heating at 150°, guanylurea was found in the product and the reaction mixture contained no appreciable amount of insoluble material. When the reaction was of longer duration or at a higher temperature, guanidine was formed and the reaction mixture contained considerable quantities of ammeline and ammelide. When the reaction was carried on for a still longer time, no guanidine was found and

<sup>1</sup> This investigation was carried out in connection with a contract between the Ordnance Department and the Massachusetts Institute of Technology, and the present paper is published by permission of the Chief of Ordnance. In this work I have been assisted by William S. Johnson. T. L. D.

<sup>2</sup> THIS JOURNAL, 43, 669 (1921).

a large quantity of melamine was isolated along with the ammeline and ammeline.

Bamberger<sup>3</sup> reports that dicyandiamide heated with water at 160–170° yields carbon dioxide, ammonia and ammeline. He reports also the formation of ammeline by heating dicyandiamide with ammonium carbonate at 120°. Either reaction would account for the formation of ammeline under the conditions of our experiments. The formation of melamine in our experiments and the disappearance of the guanidine carbonate which is first formed would seem to indicate that the melamine is produced from the guanidine salt. Smolka and Friedreich<sup>4</sup> report that guanidine carbonate at 180–190° gives carbon dioxide, ammonia and melamine, and that dicyandiamide and ammonium carbonate at 160° give the same products. We find that guanidine carbonate heated with ammonia water at 160° for 2 hours gives melamine—and believe that the formation of the mono-, di-, and tri-imides of cyanuric acid in our experiments is plausibly explained by supposing that guanidine carbonate reacts with carbon dioxide and ammonia to form first ammeline (the mono-imide), then ammeline (the di-imide), and finally melamine (the tri-imide), as follows.

When Lime-nitrogen is leached with hot water and the solution is evaporated, dicyandiamide is formed, but more or less ammonia is always produced, and the tailings from the crystallization of dicyandiamide are strongly basic, viscous and caustic liquids which deposit insoluble white materials. The foregoing considerations help to explain the genesis of these products.

### Discussion of Experiments.

**Effect of Ammonia Water.**—A systematic series of sealed tube experiments, with 4 g. of dicyandiamide and 7.5 cc. of ammonia water (sp. gr. 0.90) was carried out.

<sup>3</sup> Bamberger, *Ber.*, 16, 1074, 1703 (1883).

<sup>4</sup> Smolka and Friedreich, *Monatsh.*, 10, 91, 93 (1889).

After the heating, the contents of the tubes were rinsed out, filtered, and precipitated by the addition of ammonium picrate solution. The precipitated picrate was washed and dried, and its melting point was determined. Guanylurea picrate turns deep red at 235° and at 265° it turns black and decomposes but does not melt. Guanidine picrate melts with decomposition at 310–320°. The results were as follows:

Temperature. ° C.	Time. Hours.	Weight of G. picrate.	Melting point. ° C.
100	2	0	—
	4	0	—
	6	0	—
	8	0	—
	1	0	—
	2	trace	—
150	3	0.4	265 decomp.
	4	1.1	
	5	1.6	
	6	1.4	
	7	0.9	
	8	0.7	
*	9	0.6	310–320
*	0.5	0.8	
*170	1	1.8	
*	1.5	1.8	
180	1	2.2	
*	10 min.	0.4	
	20	— exploded	—
*	1 hour	3.2	310–320
*200	1.5	1.6	
*	2	0.6	
	2.5	— exploded	

In the experiments which are marked with an asterisk (\*) a white insoluble compound was obtained. This was filtered off before precipitating with ammonium picrate, and was later identified as a mixture of ammeline and ammeline. Since the yields of guanidine were poor, it was judged that too much ammonia water had perhaps been used, so making the reaction mixture too dilute in dicyandiamide, and another series of experiments was carried out to test this point. Four g. of dicyandiamide was used in each experiment.

Volume of ammonia water (0.90). Cc.	Time. Hours.	Temperature. ° C.	Weight of G. picrate.	Melting point. ° C.
*3	1	160	3.5	310–320
*4			3.4	
*5			4.1	
*4		170	2.5	
*4		180	2.4	
5	2	150	1.1	265
5			— exploded	—
5			3.9	265

Since the best yield was obtained by heating 4 g. of dicyandiamide with 5 cc. of ammonia water at  $160^{\circ}$  for 1 hour, an experiment with the materials in the same relative proportion was tried on a larger scale. Fifty g. of dicyandiamide and 62.5 cc. of ammonia water (0.90) were heated in an autoclave at  $160^{\circ}$  for 1 hour, but the autoclave was heavy and required several hours to cool before it could be opened, and the high temperature was actually maintained for much more than 1 hour. The reaction mixture contained no guanidine; it yielded a considerable quantity of the familiar insoluble white material, together with 13.2 g. of a substance which crystallizes from water in white glistening leaflets or in thick rhomb-shaped plates, which does not melt below  $360^{\circ}$ , and which has been identified as melamine by its properties and by analysis.

**Guanidine Carbonate and Ammonia Water.**—To test the hypothesis that the melamine was produced by the secondary reaction of ammonia on the guanidine carbonate first formed 1.5 g. of guanidine carbonate (from the thiocyanate) and 5 cc. of 6 *N* ammonia water were heated together in a sealed tube at  $160^{\circ}$  for 6 hours. The reaction mixture yielded about 1 g. of melamine, identified by its reactions and properties. It contained not more than traces of ammeline and ammelide.

**Action of Sodium Carbonate.**—To confirm the idea that the conversion of dicyandiamide to guanidine by the action of ammonia water might be due to the action of hydroxyl ions rather than to that of the ammonia itself, a tube containing 2 g. of dicyandiamide and 6.5 cc. of 3 *N* sodium carbonate solution was heated for 1 hour at  $160^{\circ}$ . The precipitated picrate weighed 1.9 g. and melted with decomposition at  $310\text{--}320^{\circ}$ .

### Summary.

Ammonia water acts on dicyandiamide in the same way that other hydrolytic agents do, converting it first into guanylurea and later into guanidine carbonate. The guanidine carbonate enters into a secondary reaction with the ammonia, and is converted finally into melamine.

## PREPARATION OF GUANIDINE NITRATE.<sup>1</sup>

BY TENNEY L. DAVIS.

Received July 1, 1921.

When the paper of Werner and Bell<sup>2</sup> appeared in which the preparation of guanidine thiocyanate is described by the heating together of dicyandiamide and ammonium thiocyanate, it occurred to us that guanidine nitrate might perhaps be prepared similarly by the heating together of dicyandiamide and ammonium nitrate. Experiment quickly confirmed the belief, and the yields were found to be excellent.

Guanidine thiocyanate is deliquescent, difficult to purify, and unpleasant to handle. The nitrate is not deliquescent; it is easy to purify, and offers advantages to the worker who wishes an easily made salt of guanidine. For the explosive industry the nitrate possesses another great advantage, for nitroguanidine prepared from the thiocyanate still contains traces of sulfur compounds and is not fit for use in nitrocellulose powder since it impairs the powder's stability and causes it to blister on storage. Nitroguanidine may be prepared in excellent yield simply by dissolving guanidine nitrate in conc. sulfuric acid and pouring the solution into water. Studies on the preparation of the nitroguanidine by this method and of its reaction with and solubility in sulfuric acid of various concentrations are now practically completed at this laboratory and will form the subject of a later communication.

In a preliminary experiment dicyandiamide and two molecular equivalents of ammonium nitrate were heated together in a test-tube in an oil-bath at 160° until the mass which first fused had become practically solid again at that temperature. The product was found to consist almost entirely of guanidine nitrate. When this result was discussed in March 1921 with the chemists of the Fixed Nitrogen Research Laboratory, it appeared that the paper of Werner and Bell had induced Mr. Blair of that laboratory to try a similar experiment. He had worked at a lower temperature (135°) and had obtained no guanidine but had obtained the nitrate of biguanide. A reaction similar to this had long ago been noted by Smolka and Friedreich<sup>3</sup> who obtained biguanide chloride by heating together dicyandiamide and ammonium chloride in alcoholic solution in a sealed

<sup>1</sup> This investigation was carried out in connection with a contract between the Ordnance Department and the Massachusetts Institute of Technology, and the present paper is published by permission of the Chief of Ordnance. In this work I have been assisted by Edward F. English. T. L. D.

<sup>3</sup> Smolka and Friedreich, *Monatsh.*, 9, 228 (1888).

tube. They found also,<sup>4</sup> as did Bamberger and Dieckmann later,<sup>5</sup> that the same materials yielded biguanide chloride if simply melted together. Rathke,<sup>6</sup> even earlier, had actually obtained guanidine by the reaction; from the heating of dicyandiamide and ammonium chloride in aqueous solution at 150° he obtained ammelide and the chlorides of biguanide and of guanidine. Blair suggested that perhaps one molecule of ammonia added to dicyandiamide to form biguanide and that the biguanide reacted with a second molecule of ammonia to form guanidine. We have verified these suggestions by experiment. Since chance had led us first to prepare guanidine nitrate, the chemists of the Fixed Nitrogen Research Laboratory very kindly agreed, in order to avoid duplication of effort, to experiment no more on the formation of guanidine nitrate by the heating together of ammonium nitrate<sup>7</sup> and dicyandiamide but to devote their attentions to other methods for the preparation of guanidine nitrate from lime-nitrogen for the study of which the peculiar facilities of their laboratory were especially adapted.

The mechanism of the reaction is as follows.

We have demonstrated the truth of these equations by showing (1) that dicyandiamide and two molecules of ammonium nitrate at 120° yield biguanide nitrate, (2) that the same materials at 160° give guanidine nitrate, and (3) that biguanide nitrate and ammonium nitrate in molecular proportions fused together give guanidine nitrate. The reaction therefore is not dependent upon the depolymerization of dicyandiamide as Werner and Bell have supposed.

Since the biguanide nitrate which is first formed by the addition of one molecule of ammonium nitrate to one of dicyandiamide is strongly basic and tends to react with a second molecule of ammonium nitrate to form the normal nitrate and to liberate ammonia, we found it expedient in preparing guanidine nitrate to work with a slight excess, *i. e.*, with 2.2 mols. of ammonium nitrate.

When a small quantity of a mixture of dicyandiamide and ammonium nitrate in molecular proportions is carefully melted in a test-tube, ammonia is given off and the product if cooled promptly contains a large quantity

<sup>4</sup> Smolka and Friedreich, *Monatsh.*, 10, 86 (1889).

<sup>5</sup> Bamberger and Dieckmann, *Ber.*, 25, 545 (1892).

<sup>6</sup> Rathke, *ibid.*, 18, 3107 (1885).

<sup>7</sup> German pat. 222,552 of October 30, 1908, ought to be noted in this connection. It describes the preparation of guanidine salts by the dry heating together of dicyandiamide and ammonium salts *in molecular proportions*. We find that two molecules of the ammonium salt are necessary for the reaction and that the product is two molecules of the guanidine salt.

of nitrate of biguanide. If, however, a larger quantity of the same mixture, say 150 g., is heated in a beaker carefully with a free flame, a violent reaction sets in at the moment that the mass fuses clear, much heat is disengaged, ammonia comes off abundantly, a white substance precipitates in the hot liquid and somewhat more than half of the dicyandiamide is converted into ammeline (along with a little ammelide) while somewhat less than half appears in the form of guanidine nitrate.

A mixture of one mol. of dicyandiamide and two mols. of ammonium nitrate heated at 120° sinters together after a time and assumes a porridge-like consistency. After 6 hours' heating the mass contains considerable unchanged dicyandiamide and ammonium nitrate together with biguanide nitrate and a small quantity of guanidine nitrate. At 130° the same mixture fuses within an hour to a clear colorless liquid which undergoes no apparent change during a further 2 hours of heating, and yields considerable guanidine and biguanide. At 120° in the autoclave with water the same mixture, after 2 hours' heating, yields the same products as when the heating is carried out for a longer time in the absence of water.

A mixture of dicyandiamide and 2.2 mols. of ammonium nitrate heated at 160° fuses to a colorless liquid which soon begins to deposit crystals and becomes practically solid at the end of 2 hours' heating. From the product we have isolated guanidine nitrate in amounts equal to more than 85% of the calculated yield. The same materials heated in an autoclave at 160° for 2 hours with water or with alcohol give practically the same yields of guanidine nitrate, but alcohol appears to be no better than water for the purpose. A temperature higher than 160° appears to offer no advantage.

Experiments with the nitrates of substituted ammonias are now under way in this laboratory.

### Discussion of Experiments.

**Sealed Tube Experiments.**—Five g. of dicyandiamide, 9 g. of ammonium nitrate, and 11 cc. of absolute alcohol were heated together in a sealed tube for 1 hour at 160°. When the tube was opened, a slight odor of ammonia was perceptible and the contents gave off a disagreeable putrid odor similar to that which is produced in the synthesis of malonic ester from chloro-acetic acid. The contents of the tube consisted of white crystalline shiny plates. On recrystallization from moist alcohol these yielded 12 g. of guanidine nitrate, m. p., 212° (pure guanidine nitrate, m. p., 215–216°); calculated yield, 14.5 g.; actual yield, 82.7%. The product was identified as guanidine nitrate by its own melting point, by the melting point of its picrate, and by the fact that it yielded nitroguanidine on treatment with sulfuric acid.

A similar experiment in which 10 cc. of water was used instead of the alcohol yielded 13 g. of guanidine nitrate, m. p., 212°; or 89.6%. We conclude that water is preferable to alcohol.

**Autoclave Experiments.**—For the purpose of determining the best conditions for the reaction, other experiments were carried out in a small autoclave of about 100cc. capacity. After the autoclave had been closed, it was immersed in a bath of heated

oil the temperature of which was determined by means of a thermometer. After the heating, the autoclave was cooled promptly by immersion first in oil and later in cold water. 16.8 g. of dicyandiamide, 33.6 g. of ammonium nitrate, and 20 cc. of water were heated at 130° for 1 hour. The first crude product amounted to 45 g. and gave a test for biguanide nitrate. Recrystallized from alcohol it was found to consist in large part of guanidine nitrate and the first crystal fraction gave no test for biguanide. The mother liquors contained biguanide, and, worked up by recrystallization from alcohol and from water, yielded about 2 g. of biguanide nitrate.

A similar experiment at 160° for 2 hours yielded, after the product was recrystallized from water, 42 g. of guanidine nitrate, m. p., 206°, and 1.2 g. of white insoluble material (ammeline and ammelide). The calculated yield was 48.8 g. of guanidine nitrate, the actual yield, 86.0%. An experiment for a longer time, 3 hours at 160°, gave practically the same result, 42 g. of guanidine nitrate, m. p., 209°, and 1.1 g. of the white insoluble by-product.

A similar experiment at a higher temperature, 180° for 2 hours, gave the same yield of guanidine nitrate, 42 g., m. p. 208–209°, but it yielded considerably more, 4.8 g., of the insoluble white material.

**Fusion Experiments.**—An experiment without any solvent gave results as gratifying as those which were obtained from the autoclave. Five g. of dicyandiamide and 9 g. of ammonium nitrate were mixed in a dry test-tube and heated in the melting-point bath at 160° for 2 hours. The mass first fused to a colorless liquid and ammonia was evolved. It soon began to deposit crystals which increased in amount as the heating was continued, and the material became an almost solid mass at the end of an hour. The heating was continued for another hour in order to drive the reaction to completion. The product was entirely soluble in water and yielded, on recrystallization from this solvent, 13 g. of guanidine nitrate, m. p. 210°; or 89.6%.

An experiment at a lower temperature yielded considerable biguanide. A mixture of 4.2 g. of dicyandiamide and 10 g. of ammonium nitrate was heated at 130° in a dry test-tube in the oil-bath. At the end of half-an-hour the mass had melted (except for a few crystals) to a colorless liquid. No further change appeared when the heating was continued for an hour. The product was readily soluble in water. Half of the resulting solution, treated with ammonium picrate, yielded 2.0 g. of guanidine picrate, m. p. 310–315°. The other half, treated with ammoniacal copper nitrate, yielded 0.6 g. of the characteristic copper-biguanide nitrate. When ammoniacal copper nitrate was added, a flocculent precipitate was produced but its color could not be seen because of the intense blue color of the solution. The precipitate was filtered off on asbestos and rinsed with water. The contents of the filter, asbestos and all, boiled up with water and filtered through paper, yielded a bright purple solution which deposited on cooling rose-colored needles of copper-biguanide nitrate.

A mixture of 84 g. of dicyandiamide and 80 g. of ammonium nitrate was carefully warmed in a Pyrex beaker. The mass started to melt readily enough, but at the moment when it fused clear, even though the flame was withdrawn, a violent reaction set in, ammonia fumes were given off in great abundance, the mass heated up greatly, effervesced, and deposited a white solid. After cooling, the product resembled chalk or porcelain. Worked up with water, it yielded 62 g. of guanidine nitrate, m. p. 209°, 56 g. of ammeline and 6.3 g. of ammelide. The mother liquors gave no test for biguanide with ammoniacal copper nitrate.

Half a gram each of biguanide nitrate and ammonium nitrate were brought to fusion together in a dry test-tube. The product, taken up in water and precipitated with ammonium picrate, yielded guanidine picrate, m. p. 316–320° with decomposition.

### Summary.

Guanidine nitrate may be obtained in excellent yield by heating dicyandiamide for 2 hours at 160° with slightly more than 2 molecules of ammonium nitrate, using either the dry materials alone or the materials and water in an autoclave.

## AN INDIRECT METHOD OF PREPARATION OF ORGANIC MERCURIC DERIVATIVES AND A METHOD OF LINKING CARBON TO CARBON.

### Preliminary Report.<sup>1</sup>

BY MORRIS S. KHARASCH.<sup>2</sup>

Received July 5, 1921.

The study of organic metallic derivatives is of considerable importance not only because of the use they can be put to synthetically, but also of the opportunity they afford to attack, from an entirely different angle, problems of great theoretical moment. The methods at our disposal suitable to the preparation of any type of mercury compound are, however, rather limited. The main difficulty arises from the fact that mercury never orients *meta* to the group already present in the molecule in the case of a mono substituted benzene derivative. Even in such compounds as nitrobenzene and benzoic acid the mercury orients to the *ortho* and not the *meta* position. This is rather significant if taken in conjunction with the fact that in the mercurization of a compound containing an electronegative group the *para* compound is formed in much larger quantity than the *ortho*.

It is, therefore, quite evident that one has to develop indirect methods of preparing mercury derivatives, otherwise the scope of investigation is necessarily limited, especially in the case of compounds containing one or more electropositive groups.

In a recent paper Kharasch and Chalkley<sup>3</sup> have shown that the sulfinic acid method can be used for introducing mercury in any desired position in the benzene molecule, by the use of the corresponding sulfinic acid, the mercury taking the place of the SOOH radical. Unfortunately the preparation of the corresponding sulfinic acids is at times exceedingly difficult, and the writer has, therefore, been led to a search for a simpler and less time consuming method.

<sup>1</sup> Read before the Organic Division of the American Chemical Society at the Rochester Meeting, March 1921.

<sup>2</sup> National Research Fellow in Organic Chemistry.

<sup>3</sup> Kharasch and Chalkley, *THIS JOURNAL*, 43, 607 (1921).

The fact that certain carboxylic acids split off carbon dioxide upon heating has suggested a method of attack, namely, heating the dry mercury salt of the acid or a solution of the latter in pyridine. The present paper deals only with the preparation of certain mercury compounds prepared by heating the dry mercury salts, and is merely a preliminary report on the subject.

It was found that when the mercury salt of 2,4,6-trinitro-benzoic acid was heated to  $210^{\circ}$ , a gas, which was later proved to be carbon dioxide, was given off. When the reaction was studied quantitatively, it was found that the amount of carbon dioxide lost corresponded to 2 molecules for every molecule of the mercury salt of the trinitro-benzoic acid. The product thus formed is undoubtedly 2,2',4,4',6,6'-hexanitro-mercury-diphenyl:

Analysis and the qualitative reactions of the compound seem to bear out this contention.

In the same way the mercury salt of 2,4-dinitro-phenylacetic acid upon heating decomposes into carbon dioxide and 2,2',4,4'-tetranitro-mercury-dibenzyl

The 2,2',4,4'-tetranitro-mercury-dibenzyl is insoluble in the common organic solvents; it is soluble, however, in pyridine from which it is precipitated out with ligroin. Care must be taken not to heat the pyridine solution, since this leads to the precipitation of mercury. This is characteristic also of the mercury salts of compounds which lose carbon dioxide readily. Thus the writer and A. P. Locke have found that the mercury salt of triphenyl-acetic acid when heated in pyridine solution gives rise to triphenyl-methyl peroxide.<sup>4</sup> While the dry mercury salt of triphenyl-acetic

<sup>4</sup> The reaction probably proceeds in two stages, as indicated by the equations given below:

1.  $(\text{C}_6\text{H}_5)_3\text{C} \cdot \text{C}(\text{O})-\text{O}-\text{Hg}-\text{O}-\text{C}(\text{O})\text{C}(\text{C}_6\text{H}_5)_3 \longrightarrow (\text{C}_6\text{H}_5)_3\text{C}-\text{Hg}-\text{C}(\text{C}_6\text{H}_5)_3 + 2\text{CO}_2$
2.  $(\text{C}_6\text{H}_5)_3\text{C}-\text{Hg}-\text{C}(\text{C}_6\text{H}_5)_3 \longrightarrow 2(\text{C}_6\text{H}_5)_3\text{C} + \text{Hg} \downarrow \xrightarrow{+\text{O}_2} (\text{C}_6\text{H}_5)_3\text{C}-\text{O}-\text{O}-\text{C}(\text{C}_6\text{H}_5)_3$

In the second stage of the reaction the mercury oxidizes the carbon and we get triphenyl-methyl which combines with the oxygen of the air to give triphenyl-methyl peroxide.

acid when heated gives rise to different products. This behavior of mercury salts of mono- and di-carboxylic acids, which lose carbon dioxide readily, in pyridine solution is under investigation and will be reported soon. The following types of compounds are under investigation at the present time as to the behavior of their mercury salts in pyridine solution and other solvents and upon dry heating: the phenylene oxydicarboxylic acids, the phenyl-paraffin-ketone carboxylic acids, the phenylketone mono and dicarboxylic acids, phenyl-alcohol dicarboxylic acids, the phenylene-ketone dicarboxylic acids, various substituted malonic acids, and other acids which lose carbon dioxide at their melting points or at slightly higher temperatures.

In the case of aromatic carboxylic acids which do not lose carbon dioxide readily, the mercury usually becomes attached to a carbon of the benzene ring. Although this has been known for a long time no systematic study has been undertaken as to the effect of the group already present in the molecule on the orientation of the mercury. Thus Dimroth has shown that when the mercury salt of benzoic acid was heated the mercury enters *ortho* to the carboxyl group. However, in the case of salicylic acid the mercury became attached to the carbon which is *ortho* to the hydroxyl group. The writer has investigated a number of substituted carboxylic acids, and although the work, so far as concerns the positions taken by the entering mercury, is not complete as yet, nevertheless it all points to the following rule: in the case of negatively substituted aromatic acids the mercury usually enters *ortho* to the negative group, irrespective of the position of the carboxyl group, while in the case of a positively substituted aromatic acid the mercury enters *ortho* to the carboxyl group.<sup>5</sup>

Thus, when the mercury salt of anisic acid is heated the mercury enters *ortho* to the methoxy group, as shown by the fact that when the mercury compound thus formed is treated with a solution of potassium periodide it gives 3-iodo-4-methoxybenzoic acid. In the same way in 3-nitro-4-methoxybenzoic acid and 3-nitro-4-hydroxybenzoic acid<sup>6</sup> the mercury enters *ortho* to the negative group, methoxy and hydroxyl respectively. Other substituted carboxylic acids such as *o*- and *m*-nitrobenzoic acids, 3,5-dinitro- and 2,4-dinitro-benzoic acids, the nitrosalicylic acids (2-nitrosalicylic acid [OH = 1] and 4-nitrosalicylic acid) have also been investigated, but the position taken by the entering mercury has not been established as yet, since the corresponding halogen derivatives of some of them are not recorded in the literature and it is necessary to prepare them by some other means. This work is now in progress.

*m*-And *o*-nitrobenzoic acids and other nitrobenzoic acids such as nitroanisic acid, besides giving rise to mercury compounds, in which the mercury

<sup>5</sup> This is not rigidly correct as will be brought out in a subsequent paper.

<sup>6</sup> Kharasch, *THIS JOURNAL*, 43, 1203 (1921).

is attached to a carbon of the benzene ring, also split off carbon dioxide especially at temperatures above 200°. Thus upon heating *o*-nitrobenzoic acid two products were obtained; one of them was found to be mercurized *o*-nitrobenzoic acid, and the other, insoluble in alkali, gave rise to nitrobenzene-*o*-mercuric chloride upon treatment with alcohol saturated with hydrogen chloride. This work is almost complete and will be reported soon.

The above mentioned method for the preparation of mercury compounds by heating the mercury salt of an acid, which loses carbon dioxide readily, would thereby enable us to replace a carboxyl group by a halogen and it is also hoped that it would have a much wider application in that by heating the mercury compound, thus formed, in the dry state or in some solvent the mercury would oxidize one of the carbons and thereby link the two carbons together. This would be especially possible in the case of the compounds where the mercury would be attached to the aliphatic residue. This observation has been made by Wolff,<sup>7</sup> incidentally, in the case of mercury dibenzyl which was found to go over into dibenzyl and metallic mercury when heated slightly above its melting point, and the writer has also observed it in the case of 2,2',4,4'-tetranitro-mercury-dibenzyl.

The writer and F. W. Stavely are engaged at the present time in working out the details and applications of this method of linking carbon to carbon.

### Experimental Part.

**The Preparation of the Mercuric Salt of 2,4-Dinitro-phenylacetic acid.**—It was found more advantageous in the preparation of the mercury salts of the substituted aromatic acids to treat a water solution of the acids with mercuric acetate, rather than by double decomposition of the sodium salts with mercuric chloride.

To a solution of 4.5 g. of 2,4-dinitro-phenylacetic acid, in 450 cc. of hot water (70°), a solution of 3.2 g. of mercuric acetate in 50 cc. of water was added in small portions, the whole being well stirred. An immediate precipitate resulted and was at once collected on a filter, washed well with water and dried *in vacuo* over sulfuric acid. Yield, 6 g. For analysis the salt was dried to constant weight *in vacuo* at 100°.

**Analysis.** Subs., 0.1844: N<sub>2</sub>, 14.00 cc. (16° and 733.2 mm.). Calc. for C<sub>16</sub>H<sub>10</sub>O<sub>12</sub>N<sub>4</sub>Hg·N, 8.59. Found: 8.66.

The compound is of a very light yellow color. When treated with sodium hydroxide solution it soon turns it dark, comparable with the behavior of 2,4-dinitro-phenyl-acetic acid. It is soluble in pyridine imparting to it a yellow color, but after a while the solution turns dark and, if warmed, metallic mercury separates. The compound has no melting point, but loses carbon dioxide when heated at 180–190° and goes over into the compound described immediately below.

<sup>7</sup> Wolff, *Ber.*, 46, 64 (1913).

**The Preparation of 2,2',4,4'-Tetranitro Mercury Dibenzyl.**—When the dry mercury salt of 2,4-dinitro-phenyl-acetic acid was heated to 180° a vigorous evolution of carbon dioxide took place and a yellow solid remained. The amount of carbon dioxide lost, as estimated by the loss in weight of the test-tube, in which the compound was contained, corresponded to two molecules for every molecule of the mercury salt of 2,4-dinitro-phenyl-acetic acid. The melting point of the compound thus obtained is 215°. After washing with acetone, in which the substance is insoluble, the melting point was raised to 235°.

For analysis the compound was dissolved in pyridine and filtered from the small amount of mercury with which it is contaminated. It was then precipitated with ligroin, and dried to constant weight *in vacuo* over sulfuric acid.

**Analysis.** Subs., 0.1280: N<sub>2</sub>, 11.30 cc. (22° and 732.5 mm.). Calc. for C<sub>14</sub>H<sub>10</sub>O<sub>8</sub>N<sub>4</sub>Hg: N, 9.97. Found: 9.83.

The compound is insoluble in all common organic solvents except pyridine and is precipitated from a solution of the latter by ligroin as a bright red powder. When the pyridine solution of the compound is heated mercury separates. It is insoluble in sodium hydroxide and also does not change color when heated with it. It melts with decomposition rather sharply at 235°, with separation of mercury.

**The Preparation of the Mercuric Salt of 2,4,6-Trinitrobenzoic Acid.**—To a solution of 5.2 g. of 2,4,6-trinitrobenzoic acid dissolved in 350 cc. of hot water, a solution of 3.4 g. of mercuric acetate in 20 cc. of water, was added. A beautiful white compound separated. The whole was then cooled, and the precipitate collected on a filter, washed several times with small amounts of cold water and dried *in vacuo* over sulfuric acid. Yield 6.1 g.

For analysis the substance was dried to constant weight *in vacuo* at 100°.

**Analysis.** Subs., 0.1078: N<sub>2</sub>, 11.50 cc. (21° and 737.8 mm.). Calc. for C<sub>14</sub>H<sub>4</sub>O<sub>10</sub>N<sub>6</sub>Hg: N, 11.81. Found: 12.03.

The salt gives the same reactions with sodium hydroxide as does trinitrobenzoic acid. It begins to give off carbon dioxide at 210° and goes over into the compound described below.

**The Preparation of 2,2',4,4',6,6'-Hexanitro Mercury Diphenyl.**—The mercury salt of 2,4,6-trinitrobenzoic acid contained in a test-tube, was heated to 210°, by immersing the latter in a sulfuric acid bath, and kept at that temperature until no more carbon dioxide was evolved. The loss in weight corresponds quantitatively to two molecules of carbon dioxide for every molecule of the mercury salt. The contents of the test-tube were then extracted with acetone. Most of the substance goes in solution and can be obtained in fairly pure condition by concentrating the acetone extract, decanting the mother liquor from the precipitate formed, and washing the latter with ether. It is best, however, to recrystallize it from a mixture of acetone and alcohol.

For analysis the substance was dried *in vacuo* at 100°.

**Analyses.** Subs., 0.5005: HgS, 0.1832. Subs., 0.1755: N<sub>2</sub>, 21.00 cc., (22° and 724.5 mm.). Calc. for C<sub>12</sub>H<sub>14</sub>O<sub>12</sub>N<sub>6</sub>Hg: N, 13.43; Hg, 31.23. Found: N, 13.27; Hg, 31.57.

The compound is white and crystalline with a faint suggestion of yellow. It is soluble in acetone, very slightly soluble in alcohol and almost insoluble in ether. It dissolves in pyridine imparting to the solution a pink color, and when heated in it, the pink color changes immediately to a green-purple. Upon exposing the solution to the air it becomes yellow and a precipitate separates which is insoluble in acetone. It melts rather sharply at 272°, and the melt does not separate any mercury when heated to 295°.

When suspended in water and treated with potassium periodide or potassium per-

bromide the mercury is not removed from the benzene ring even in the course of 10 days, as evidenced by the fact that the compound can be recovered unchanged. However, with mercuric chloride the reaction is normal. This anomalous behavior with potassium periodide is perhaps due to the fact that water does not moisten the compound.

**The Preparation of 2,4,6-Trinitro-phenyl-mercuric chloride.**—To 0.8 g. of 2,2',4,4',6,6'-hexanitro-mercury-diphenyl, suspended in 50 cc. of alcohol, 0.35 g. of mercuric chloride was added, and the whole was heated on the hot plate for 3 hours. The unchanged 2,2',4,4',6,6'-hexanitro mercury diphenyl was filtered off (0.25 g.), and the filtrate evaporated to dryness. Weight, 0.75 g. It was crystallized from alcohol.

For analysis the compound was dried *in vacuo* at 100°.

**Analysis.** Subs., 0.1937 : N<sub>2</sub>, 16.20 cc. (22° and 732.9 mm.). Calc. for C<sub>6</sub>H<sub>2</sub>O<sub>6</sub>N<sub>6</sub>ClHg: N, 9.38. Found: 9.33.

The compound is of an exceedingly light yellow color so that it appears to be almost white. It is soluble in alcohol, ether and acetone. It melts at 202° to a clear liquid.

**Preparation of 2,4,6-Trinitro-iodo-benzene and 2,2',4,4',6,6'-Hexanitro-diphenyl.**—To a suspension of 1.1 g. of 2,4,6-trinitro-phenyl-mercuric chloride in 30 cc. of water, 7 cc. of solution of potassium periodide (0.1 g. of iodine per cc.), and 5 g. of potassium iodide were added. The mixture was then agitated on the shaking machine for one hour and the precipitate collected on a filter. It was then washed well with water and dried in the oven at 100°. When completely dry the precipitate was extracted with ether. A residue remained which melted at 240° and is probably as 2,2',4,4',6,6'-hexanitro-diphenyl. The ether extract was evaporated to dryness. A very light yellow compound was thus obtained. It melted at 164–165° and was identified as 2,4,6-trinitro-iodo-benzene.

### Summary.

1. It has been shown that when the mercury salts of certain carboxylic acids are heated, carbon dioxide is split off and the mercury takes the place originally occupied by the carboxyl groups.

2. The preparation of the mercury salts of 2,4-dinitro-phenylacetic acid and 2,4,6-trinitrobenzoic acid is given as well as the compounds derived from them: 2,2',4,4'-tetranitro mercury dibenzyl, 2,2',4,4',6,6'-hexanitro mercury diphenyl, and 2,4,6-trinitro-phenyl-mercuric chloride.

3. It has been shown that when 2,4,6-trinitro-phenyl-mercuric chloride is treated with potassium periodide it gives rise to 2,4,6-trinitro-iodo-benzene, and presumably to 2,2',4,4',6,6'-hexanitro-diphenyl.

## THE INFLUENCE OF CERTAIN FACTORS UPON THE CHEMICAL COMPOSITION OF SAUERKRAUT.<sup>1</sup>

BY O. R. BRUNKOW, W. H. PETERSON, AND E. B. FRED.

Received July 5, 1921.

The production of sauerkraut is an excellent illustration of the economic value of a fermentation process in the preservation of human food. It is an acid fermentation and in many respects is like that obtaining in the formation of silage, pickles, and dairy products. The art of making sauerkraut has been known and practiced for many years, but until recently little attention has been given to the different agents and factors involved in the process. Since the fermentation is a spontaneous one, it is evident that the type of flora which develops is the result of native and competing micro-organisms. Some of these organisms are desirable while others are objectionable. Although the lactic acid bacteria tend to dominate the fermentation, other bacteria or yeasts frequently develop and produce undesirable colors or flavors. The production of good kraut is, therefore, more or less a matter of chance and it is probable that inoculation with suitable bacteria will result in a better and more nearly uniform product.

The type of organisms present and the nature of the products formed in the production of sauerkraut were not studied until comparatively recent years. One of the earliest investigators in this field was Reichardt<sup>2</sup> who made an approximate analysis of sauerkraut and discussed its wholesomeness and food value.

In 1897 Conrad<sup>3</sup> made the first serious attempt to study the biochemical changes involved in the production of sauerkraut. He made a bacteriological examination of both cabbage and sauerkraut, and isolated two yeasts and an organism, *Bacterium brassicae acidae*, which he regarded as the chief agent responsible for the fermentation. With this bacterium he carried out a number of fermentations of cabbage and various carbohydrates to determine its fermentation characteristics, and its usefulness in the production of sauerkraut. Besides his work on the organisms of sauerkraut, he has supplied the most complete chemical analysis of this product that has been published. He reported the production of formic, acetic, butyric, and lactic acids, ethyl alcohol, carbon dioxide, methane, and hydrogen as a result of fermentation processes. The lactic acid was found to be inactive, and tests for acetone and mercaptans were negative. About the same time as Conrad's publication, a paper by Krause<sup>4</sup> appeared in which the acidity of sauerkraut was asserted to be due almost entirely to lactic acid with only a trace of acetic acid.

<sup>3</sup> Conrad, *Arch. Hyg.*, 29, 56 (1897).

<sup>4</sup> Krause, *Apoth. Ztg.*, 12, 88 (1897).

In 1905 Wehmer<sup>5</sup> published two long papers on the types of organisms present in sauerkraut and the effect of inoculation, temperature, salts, and water on the quality of the kraut. He isolated and studied the fermentation characteristics of 2 bacteria and 5 yeasts. The organism which he considered as most important in the formation of the acid in sauerkraut was a short rod-form, *Bacterium brassicae*, which grew under both aerobic and anaerobic conditions and produced a high concentration of acid. The other type of bacterium was a long slender rod and produced only a small quantity of acid. The 5 yeasts were divided into 2 classes: bottom yeasts which produced gas and alcohol, and surface yeasts which destroyed the acids that had been formed earlier in the fermentation.

In 1905 Perekalin<sup>6</sup> isolated an organism from kraut, which he deemed typical of sauerkraut because of its growth and persistence in a highly acid medium.

In 1909 Gruber<sup>7</sup> isolated an organism *Pseudomonas brassicae acidae*, which when used in pure cultures gave a kraut of good flavor and shortened the period of fermentation.

Round<sup>8</sup> published a short note in 1916 calling attention to the large number of organisms present in the vats of commercial plants, and concluded that bacteria alone are concerned in a proper fermentation.

The papers of Henneberg<sup>9</sup> published in 1917, give a very extensive discussion of the manufacture of sauerkraut. In his bacteriological work on the flora of kraut he found 8 different yeasts, 7 strains of lactic acid bacteria, 2 colon types, 1 acetic acid type, and 5 molds. The bacteria which he considered the most important were *Bacterium lactis acidii*, and *Bacillus cucumeris fermentati*, a long rod related to Wehmer's *Bacterium brassicae*. The most important yeast was a small celled form, *Saccharomyces panis fermentati*. He studied the influence of inoculation with pure cultures of organisms upon the fermentation of sauerkraut, and obtained the best results by inoculating with a mixed culture of lactic acid bacteria and yeasts.

Nelson and Beck<sup>10</sup> published a short article in 1918 on the fermentation products found in sauerkraut. They reported the volatile acids to consist largely of acetic and a small proportion of formic and propionic acids. The alcohols were found to be mainly ethyl alcohol and a small amount of propyl alcohol.

In recent papers Le Fevre<sup>11</sup> has discussed the effect of temperature and the use of pure cultures on the production of sauerkraut. While inoculation aids in the fermentation of the cabbage, he considered temperature to be the most important factor in bringing about a rapid and satisfactory fermentation.

From the foregoing review of the literature it is clear that little is known concerning the kinds and amounts of fermentation products contained in sauerkraut.

### Experimental.

The object of this work included the determination of the main products formed in sauerkraut during a normal fermentation and the influence of

inoculation on the products formed, and quality of the sauerkraut. The effect of salt concentration on the quality of the sauerkraut was also noted.

Most of the kraut was made under laboratory conditions, but two tanks were made on a commercial scale; one of these was inoculated with a pure culture of organisms and the other was left uninoculated in order to serve as a control.<sup>12</sup>

The kraut made under laboratory conditions consisted of 6 series of fermentations, comprising 61 separate samples. In each series 2 containers were always used as controls. In these the usual amount of salt (2-2.5%) was used and the cabbage allowed to ferment normally. To the other containers in the series pure cultures of organisms were added.

The fermentations were carried out in glass percolators of 2-liter capacity. The bottom of each percolator was fitted with a 1-hole rubber stopper, through which was passed a glass tube closed at the lower end with a piece of rubber tubing and a pinchcock. Some glass wool was placed over the end of the glass tube inside the percolator to prevent the cut cabbage from plugging the tube. This arrangement allowed the brine to be readily drawn from the bottom of the container without disturbing its contents. Fifteen hundred g. of cut cabbage, the weight usually taken, was prepared by removing the outer leaves and the cores of the cabbage and cutting with a hand cutter. The salt was mixed with the cabbage in a large pan and when cultures of organisms were used they were added at this time to insure uniform distribution. The whole was then transferred to the percolator. A large paraffined cork, slightly smaller than the inside diameter of the percolator, was placed over the cabbage, and this was held down by a bottle containing 1 kg. of mercury or sand.

The main chemical changes in the production of good sauerkraut involve the destruction of the sugars in the cabbage, resulting in the formation of volatile and non-volatile acids, alcohol, and mannitol. A decrease in the toughness of the cabbage and the development of a translucent appearance accompany this change.

Observations of the color and texture of the cabbage, as well as titrations of the brine were made daily during the first 6 to 8 days of the fermentation period, after which they were made at longer intervals. Titrations were made on the brine from the top and bottom of several containers to determine whether there existed any difference in the acidity. In one series stained mounts were made daily, and at the end of the fermentation, of the brine from the control and of the brine inoculated with *B. lactis acidii*. In several experiments counts were made of the number of micro-organisms present in the brine. From the data secured from a study of commercial kraut, inoculation appeared to increase the number of bacteria present,

<sup>12</sup> The authors desire to express their appreciation to the Onalaska Canning Company, Onalaska, Wisconsin for their cooperation in carrying out this part of the work.

but this was not true of the kraut made in the laboratory. The number of micro-organisms present in the samples of kraut investigated varied from about 500,000 to 91,000,000 per cc. of brine.

The rate at which the fermentation proceeds can be measured by titrating portions of the brine from day to day, and can be influenced by the temperature under which the fermentation takes place and the flora which is present.

The curves in Fig. 1 represent typical titrations of the rate and amount of acid developed and the influence of inoculation with pure cultures of organisms. It will be seen that in the case of the inoculated kraut there is an increase in the development of acidity over the control during the first few days. A fall in the amount of acid on about the tenth or twelfth day seemed characteristic of both fermentations. This decline was

Fig. 1.—The influence of inoculation upon the development of acidity.

followed by another distinct rise in a few days. This second rise as well as the first one was invariably more pronounced in the inoculated fermentations than in the control. After the twenty-fifth day there was seldom much change in the amount of acid in the brine from the bottom of the container. However, there is always a marked decrease in the acidity of brine from the top, due to the destruction of the acid by *mycodermae*. The acidity at the top and bottom of the percolators was followed closely in several fermentations and it was found that during the first four days of the fermentation period there was practically no difference between the two. On the fifth day there was an increase in the acidity of the brine

from the top over that from the bottom except in one case where a great many *mycodermae* had developed. The acidities of the brine from the top exceeded those of the brine from the bottom until the fourteenth day when they generally fell below those of the bottom brines.

**Influence of salt concentration.**—It has been reported by some investigators that good kraut can be made without salt. With this idea in view 4 fermentations were carried out in the absence of salt. Two were inoculated with a pure culture of *Lactobacillus pentoceticus* while the other two were left uninoculated. All 4 made a product having a bad odor, a sour and bitter taste, and a dark color. The data in Table I show that those inoculated produced higher acidity than the controls. This would be expected because Culture 41-11 is an organism forming a high degree of acidity.

In another series the salt content was increased from 2.0 to 3.5%. Although the flavor was good, a salty taste was predominant and the kraut was tough. In this experiment the control krauts developed a higher acidity than those which were inoculated with pure cultures. The reason for this is probably due to the sensitiveness of Culture 41-11 to a high salt concentration.

For the remaining series a concentration of 2 or 2.5 % of salt based on the weight of the cut cabbage was used and at either concentration very good results were secured with and without inoculation.

**Influence of inoculation.**—In Table II the results of a large number of inoculations with pure cultures are given; 50 cc. of a 48-hour yeast-water culture was used for each 1500 g. of cut cabbage, and to the controls 50 cc. of distilled water was added in place of the inoculating material.

Cultures 41-11 and 118-8 are the same type of organism and are named *Lactobacillus pentoaceticus*. They are essentially acid producers and ferment such sugars as xylose, arabinose, glucose, galactose, mannose, and fructose with the formation of lactic and acetic acids, ethyl alcohol, carbon dioxide, and mannitol. Cultures 52-7 and 124-1 were isolated from sauerkraut during this study; Culture 52-7 has the same characteristics as 41-11; 124-1 is a pentose-fermenter but does not belong to the same group as 41-11. Cultures 52-3 and 85 are yeasts and were isolated during this study from commercial sauerkraut that had turned red. These yeasts were found to produce red pigments when grown on agar plates. A report of red kraut and the factors influencing its formation is given in another paper now in press. The mixed culture was isolated from sauer-

kraut but the characteristics of the organisms present were not determined. Strains of *B. lactis acidi*, and *B. bulgaricus* were also used.

From the remarks in Table II on the quality it will be seen that there are certain organisms which uniformly produce good kraut when used in pure culture. In the commercial kraut it was thought that Culture 41-11 produced a grade of sauerkraut superior to the uninoculated, but this could not be duplicated in the laboratory fermentations. The one organism which was always found to produce an especially good kraut was a

strain of *B. lactis acidii*. This organism was used in 3 series and produced the best kraut of the series each time. The product has a desirable appearance, a mild, pleasant odor and taste, and good texture. Although it does not produce acid as rapidly as some of the other organisms, nevertheless, kraut inoculated with this organism was declared ready to can after fermenting for 14 days. In contrast to the favorable results obtained with *B. lactis acidii* was the production of pink kraut whenever Culture 124-1 was used for inoculating. Culture 124-1 is a high acid-forming organism and appears to favor the development of the yeasts which produce the red pigment. Aside from this the kraut was of fair quality.

From the brine of several inoculated and uninoculated fermentations microscopic mounts were made. In nearly every case where pure cultures were used it was found that these organisms predominated throughout the fermentation period. In the last series of fermentations the flora was watched closely in both the uninoculated and inoculated kraut. Stained microscopic mounts were made daily on the brine. It was found that in the brine from the control the organisms were yeasts and long rod, short rod, and coccus forms of bacteria. The rod forms were about equal in distribution and were less numerous than the coccus forms during the first 7 or 8 days of the fermentation. After this time the long rod forms increased in number and were predominant at the end of the fermentation period.

In several of the series of experiments wet microscopic mounts were made and examined at the time the sauerkraut was removed from the containers. A comparison of the number of yeasts with that of the bacteria could be roughly determined in this manner and whenever yeasts were in excess over bacteria or were predominant in the field the kraut was invariably poor. It was also true that whenever the kraut turned red large numbers of yeasts were found to be present.

**Chemical Analyses.**—The kraut was removed from the containers and the brine pressed out with a powerful hand press. A small sample of the kraut was dried at 105° to constant weight to obtain the moisture content. A sample of the brine was used for determining the total titratable acidity and the remainder was used for determining the volatile acid, non-volatile acid, and alcohol. The methods outlined by Fred, Peterson and Davenport<sup>13</sup> were used in determining these constituents. A portion of the brine was distilled with steam and the volatile acids were titrated with 0.1 N barium hydroxide solution. The residue from the steam distillation was placed in a Kutscher and Steudel<sup>14</sup> apparatus and extracted with ether to obtain the non-volatile acids. The alcohols were determined in another portion of the brine by saturating it with sodium chloride and

<sup>13</sup> Fred, Peterson and Davenport, *J. Biol. Chem.*, 39, 347 (1919).

<sup>14</sup> Kutscher and Steudel, *Z. physiol. Chem.*, 39, 473 (1903).

distilling the alcohol which was in turn oxidized to the corresponding acid with potassium dichromate. The acid formed was distilled off and titrated with 0.1 *N* barium hydroxide solution. In all of the determinations

<sup>a</sup> This kraut had developed a pink color.

<sup>b</sup> This kraut was of good quality.

the barium salts formed were evaporated to dryness and used for the identification of the acids and alcohols. The results of a number of analyses on commercial and laboratory kraut are given in Table III.

The data show a fair agreement in the case of the uninoculated krauts, both laboratory and commercial, in all the products except in the alcohols. It has been shown by Peterson and Fred<sup>15</sup> that alcohol is easily lost by evaporation from a fermenting solution. Since the containers were not covered, it may well be assumed that alcohol was lost during fermentation while gases were escaping from the brine. Cultures 52-7 and 41-11 are the same type of organism and produce the same products. They are essentially high acid- and alcohol-producing organisms and a glance at the table will show that these products were characteristic of the fermentation. In kraut inoculated with *B. lactis acidi* large amounts of lactic acid would be expected. The data in the table are in harmony with this view, although the presence of volatile acid and alcohol indicate the activity of other organisms.

The analysis of kraut containing no salt shows an unusually high content of volatile acid with a very low content of non-volatile, and very little difference in the amount of alcohol. The absence of salt has evidently favored the growth of volatile acid and alcohol-producing organisms. The acids and alcohol from this fermentation were not identified, but butyric acid was suggested by a very disagreeable taste and odor. Butyric acid has been reported by Wehmer<sup>16</sup> in kraut made without salt.

<sup>15</sup> Peterson and Fred, *J. Biol. Chem.*, 42, 273 (1920).

**Identification of Products.**—In the identification of the volatile acids three methods were used: the fractional precipitation and analysis of the silver salts; the Duclaux analysis; and the determination of the barium content of the barium salts. The barium salts of the volatile acids were dissolved in water, filtered from any insoluble material, and the filtrate made up to a definite volume. The qualitative method of Orla-Jensen<sup>16</sup> was used to determine what acids were present. From the solution of the barium salts the acids were fractionally precipitated as the silver salts by the addition of 2 *N* silver nitrate. The silver salts of the acids of highest molecular weight come out first and contain the lowest percentage of silver. After precipitation, the several fractions of silver salts were dried, weighed, and ignited to determine the silver content. In each fraction

		0.2846	0.2878	

except the first, which was slightly contaminated with chlorides, the percentage of silver was always in very good agreement with that required for pure silver acetate. This result led to the conclusion that only acetic acid was present, and the correctness of this conclusion was proven by a determination of the barium content of the barium salts, and by a Duclaux

<sup>16</sup> Orla-Jensen, *Landw. Jahrb. d. Schweiz*, 18, 314 (1904).

determination on the free acid. It will be seen from Table IV that the Duclaux constants are in very good agreement with those obtained with our apparatus on pure acetic acid. Table V shows the barium content to be very close to the calculated value for pure barium acetate. From these results it is believed that acetic acid was the only volatile acid present.

This was further substantiated by liberating 50 cc. of 0.1 *N* acid from the barium salt by the addition of an equal amount of sulfuric acid. The solution was distilled with steam and the acids in the distillate subjected to a Duclaux determination. Since the acids of higher molecular weight are more volatile than acetic, they should have been collected by this method in excess over acetic. However, it will be seen from Table IV that the results of the Duclaux determination are almost identical with those of the first analysis and are in good agreement with those for pure acetic acid. The barium content was determined on the barium salts of this fraction and it was found to agree closely with the barium content in the first analysis and the theoretical value for pure barium acetate. From these results apparently acetic acid was the only volatile acid present.

The identification of the volatile acid formed from the oxidation of the alcohol was carried out in the same manner as the identification of the volatile acid in the kraut. The results of the Duclaux determination appear in Table IV, and the barium content of the barium salt is given in Table V. Since these are in such good agreement with pure acetic acid it is concluded that only acetic acid was present and, therefore, ethyl alcohol was the only alcohol present.

In identifying the non-volatile acids the barium salts were dissolved in water and filtered from any insoluble material. After the filtrate was evaporated to about 30 cc. it was made up to 300 cc. with absolute alcohol. If any barium succinate were present, it would be precipitated at this point because it is insoluble in 90% alcohol. The only precipitate which formed was a sticky wax-like substance which was readily soluble in small amounts of water. The alcohol solution of the barium salt was then filtered, made

TABLE VI.  
WATER OF CRYSTALLIZATION IN ZINC LACTATE.

Source of acid.	Wt. of zinc lactate used.		Water lost.		Water in Zn (C <sub>2</sub> H <sub>3</sub> O <sub>2</sub> ) <sub>2</sub> + 3H <sub>2</sub> O. %
	G.	G.	%.	%.	
Uninoculated kraut (1)	0.8780	0.1597	18.26		18.17
(2)	2.3730	0.4334	18.19		18.17
Kraut inoculated with 41-11	(1) 0.9568	0.1726	18.04		18.17
	(2) 0.7485	0.1356	18.11		18.17

up to volume and aliquot portions were taken for determining the barium content of the barium salts. The data are given in Table V and will be found to agree very well with the barium content of pure barium lactate. The remainder of the alcoholic solution of the barium salts was used for

making the zinc salts. This was done by distilling the alcohol and taking up the barium salts in water. The zinc salts were then formed by the addition of 0.5 *N* zinc sulfate solution. After the barium sulfate was filtered off the filtrate was concentrated to a small volume (20–30 cc.) from which the zinc lactate was allowed to crystallize. The kind of lactic acid present was determined by obtaining the water content of the zinc lactate. From Table VI it will be seen that these results are in very good agreement with those of the zinc salts of inactive lactic acid. From these data it appears that inactive lactic acid is the form of acid produced in the fermentation.

**Mannitol.**—One quantitative determination of mannitol was made in the following manner. The residue in the extraction apparatus after the non-volatile acids had been removed was freed from ether and neutralized with barium hydroxide. The precipitate of barium sulfate was filtered off and the filtrate evaporated to dryness on asbestos, from which the mannitol was extracted, by continuous extraction with boiling absolute alcohol. This extraction was continued until a 12-hour extraction recovered no trace of mannitol. The mannitol is insoluble in cold absolute alcohol and crystallizes out readily. Absolute alcohol is an improvement over 90 or 95% alcohol because it extracts the mannitol practically free from salt. It is difficult to separate mannitol from sodium chloride by crystallization if they are extracted together.

Feder<sup>17</sup> used 90% alcohol for extracting the mannitol and states that his product contained about  $\frac{1}{3}$  salt. The results obtained are much lower than those reported by other investigators. In four determinations Feder found from 0.8 to 1.16%, while Nelson and Beck<sup>10</sup> found from 1.9 to 2.5% of mannitol. In a natural fermentation such as sauerkraut the amount of mannitol present is largely a matter of chance. It is formed by certain bacetria which ferment a part of the fructose to acids, etc., and at the same time reduce another part of the fructose to mannitol. The mannitol thus formed may subsequently be destroyed by the bacteria that produced it or by many other bacteria which use mannitol as a source of carbon. Cabbage contains approximately 4% of sugar, and it is probable that not more than half of this is fructose. Since the highest conversion of fructose to mannitol reported by Gayon and Dubourg,<sup>18</sup> was 66%, the above results appear very high. By extracting with absolute alcohol only 0.27% of mannitol was found. This had a melting point of 165°.

### Summary.

From the results of 61 experiments it appears that inoculation with certain organisms produces a better grade of sauerkraut than is produced

<sup>17</sup> Feder, *Z. Nahr. Genussm.*, 22, 295 (1911).

<sup>18</sup> Gayon and Dubourg, *Ann. inst. Pasteur*, 15, 527 (1901).

by a natural fermentation. Although an improved product was obtained with several different organisms the only one which was consistently better than the control was *B. lactis acidi*. The data are not extensive enough to recommend the use of inoculation on a commercial scale. Further experiments are needed.

That the organisms used for inoculation dominated the fermentation was indicated by microscopic mounts made from the brine at intervals throughout the fermentation period. A chemical analysis also showed the characteristic products normally formed by these organisms.

The presence of large numbers of yeasts may cause red kraut, and undesirable flavors.

The best kraut was obtained when approximately 2.0% of salt was used. With concentration above 3.0% the kraut was tough and too salty.

The chief products formed in the fermentation of kraut are lactic acid, acetic acid, and ethyl alcohol. Mannitol in varying amounts may also be formed, depending upon the type of organisms present. These same products occur in a natural fermentation, but the relative amounts can be influenced by inoculation.

[CONTRIBUTIONS FROM THE CHEMICAL LABORATORY OF THE UNIVERSITY OF ILLINOIS.]  
2-PHENYLQUINOLINE-4-CARBOXYLIC ACID-6-ARSONIC ACID.<sup>1</sup>

By J. R. JOHNSON WITH ROGER ADAMS.<sup>2</sup>

Received November 28, 1921.

In connection with the investigations being carried on in this laboratory on arsenic compounds of possible therapeutic value, 2-phenylquinoline-4-carboxylic acid-6-arsonic acid has been prepared. It is formed by the action of pyruvic acid on benzaldehyde and arsanilic acid, and is the simplest of a large number of compounds which may be made in a similar manner. This communication is merely a preliminary notice of a rather extensive research which has been carried out in this laboratory during the past 2 years upon various quinoline arsonic acids, their reduction products and other derivatives.

When aniline<sup>3</sup> and some of the simplest aniline derivatives are treated with pyruvic acid and an aromatic aldehyde, it is generally possible to obtain both a phenyl-cinchoninic acid derivative and a phenyl-diketo-

<sup>1</sup> The expenses involved in the research described in this communication were partially defrayed by funds granted by the United States Interdepartmental Social Hygiene Board.

<sup>2</sup> This is a description of a portion of the laboratory work submitted by J. R. Johnson in partial fulfillment of the requirements for the degree of Doctor of Philosophy in Chemistry at the University of Illinois.

<sup>3</sup> *Ber.*, 41, 3884 (1908).

pyrrolidine derivative. With the arsonated anilines in alcoholic suspension or solution, the reactions seem to run chiefly to the quinoline derivatives. 2-Phenylquinoline-4-carboxylic acid-6-arsonic acid is readily soluble in alkali hydroxides and carbonates and ammonium hydroxide and these solutions give precipitates with the salts of many of the heavy metals. The fact that the substance described gives off one mole of carbon dioxide on heating, and in addition forms a trisodium salt, proves without question its constitution.

### Experimental.

A mixture of 21.7 g. (1 mole) of arsanilic acid, 10.6 g. of benzaldehyde (1 mole) and 200 cc. of absolute alcohol is heated to boiling under reflux on a steam-bath. After a short while most of the arsanilic acid passes into solution and 8.8 g. of pyruvic acid (1 mole) is now added. The solution is heated to boiling for  $3\frac{1}{2}$  to 4 hours, and then filtered hot to remove a slight amount of insoluble material. On cooling the filtrate, a yellow precipitate results which is filtered, washed sparingly with cold alcohol, finally with ether and then dried *in vacuo*. The crude 2-phenylquinoline-4-carboxylic acid-6-arsonic acid thus obtained is pale yellow in color and melts with complete decomposition at  $180-183^{\circ}$ . After one crystallization from ordinary alcohol and washing with alcohol followed by ether, the substance is pure and is then a cream colored powder which starts to darken at about  $180^{\circ}$  and melts with decomposition at  $186-187^{\circ}$  (corr.).

The compound forms a neutral disodium salt and a slightly alkaline tri-sodium salt. From a solution of the disodium salt, copper sulfate precipitates a green salt; silver, lead, mercurous, mercuric, cadmium nitrates light yellow salts and cobalt and ferric nitrates reddish brown salts. In order to show that the compound is a quinoline derivative, its decomposition by heating was carried out in the following way. A definite weight of the substance was suspended in ethyl benzoate and then heated to boiling for 20 minutes. Enough carbon dioxide was evolved to correspond to one mole. Owing to the fact that a gummy material is produced during the decomposition, the reaction was not as complete as might be desired, so the analytical results showed between 5 and 10% too small an amount of carbon dioxide for the amount of substance used. Phenyl-diketopyrrolidine derivatives do not decompose in this manner.

The arsenic was determined by Ewins' method<sup>4</sup> the nitrogen by the Kjeldahl method and the carbon by the Parr total carbon method.<sup>5</sup>

### NOTE.

**Bromo-quinaldines.**—6-Bromo-quinaldine has been prepared by Barton and MacCollum<sup>1</sup> by the condensation of *p*-bromo-aniline and acetaldehyde, but, this method not proving satisfactory for our purposes, the following method was used.

Ten g. of *p*-bromo-aniline was mixed with 13 g. of conc. hydrochloric acid. The mixture was cooled and 6 g. of paraldehyde was added. Condensation was brought about by heating the mixture on a boiling-water bath during 3 hours. Five hundred g. of water was added, and the aldehyde resin coagulated by heating on the water-bath. The clear liquid was then poured off, made alkaline and distilled with steam.

The crude mixture thus obtained was heated with an equal bulk of acetic anhydride at 100° for 15 minutes, the excess of acetic anhydride removed by boiling with alcohol and subsequently evaporating the ester, and the solid extracted with chloroform in the cold and crystallized from light petroleum ether.

**6-Bromo-quinaldine Methiodide.**—A mixture of 10 g. of 6-bromo-quinaldine and 6.4 g. of methyl iodide was heated for 24 hours in a sealed tube at 79–80°. A yellow crystalline solid was obtained which, when crystallized from alcohol, gave 12 g. of greenish-yellow needles melting at 237° (decomp.).

*Analysis.* Subs., 0.3110: AgI, 0.1995. Calc. for  $C_{11}H_{11}BrNI$ : I, 34.9. Found: 34.7.

**6-Bromo-quinaldine Ethiodide.**—A mixture of 16.1 g. of 6-bromo-quinaldine and 11.7 g. of ethyl iodide was heated in a boiling-water bath for 36 hours. The product was purified as above. M. p. 218°.

*Analysis.* Subs., 0.3000: AgI, 0.1860. Calc. for  $C_{12}H_{12}BrNI$ : I, 33.6. Found: 33.5.

*m*-Bromo-aniline was condensed with paraldehyde in the same way and the crude oily product diazotized and distilled with steam to get rid of the unchanged primary amine. A yellow solid was obtained (11 g.) which was heated with 3.5 cc. of nitric acid, sp. gr. 1.42, in 20 cc. of water. Yellow crystals of bromo-quinaldine nitrate were obtained and the base precipitated from an aqueous solution with ammonia. It was recrystallized from petroleum ether (60–80°), when white leaflets melting at 77° were obtained.

*Analyses.* Subs., 0.1735: CO<sub>2</sub>, 0.3470; H<sub>2</sub>O, 0.636. Calc. for  $C_{10}H_8BrN$ : C, 54.3; H, 3.7. Found: C, 53.97; H, 3.99.

Subs., 0.2393: AgBr, 0.2015. Calc. for  $C_{10}H_8BrN$ : Br, 35.98. Found: 35.83.

When condensations are made with paraldehyde and *m*-bromo-aniline, it is evident that two bromo-quinaldines may be obtained, the bromine atom in the *meta* position with respect to the amino group in the primary base occupying the 5-, or 7-, position in the bromo-quinaldine. Only one of these two possible isomers has been isolated. The position of the bromine atom has been left undetermined for the present.

The ethiodide was prepared in the same way as the ethiodide of 6-bromo-quinaldine, m. p. 217°. The nitrate melts at 102°. The salts of the other two common mineral acids are very soluble in water. The double salts with zinc chloride, mercuric chloride and stannic chloride have been prepared by boiling together solutions in hydrochloric acid

<sup>1</sup> Barton and MacCollum, *THIS JOURNAL*, 26, 704 (1904).

of the base and the respective salts: (a) *bromo-quinaldine zinc chloride*, colorless needles, soluble in water, m. p. 268°; (b) *bromo-quinaldine stannic chloride*, colorless leaflets, insoluble in water; (c) *bromo-quinaldine mercuric chloride*, colorless needles, soluble in water, m. p. 245°; (d) *bromo-quinaldine picrate*, yellow leaflets insoluble in alcohol, crystallized from acetone, m. p. 207°.

The above preparations were carried out during the course of an investigation on the modifications in photographic sensitiveness brought about by the introduction of bromine in the benzene ring of the quinaldine nucleus of pinaverdol and pinacyanol.

The author's thanks are due to Professor W. J. Pope of Cambridge University who directed this work, and to Mr. W. H. Mills, for their advice and guidance.

## NEW BOOKS.

**Tables of Physical and Chemical Constants and Some Mathematical Functions.** Fourth edition. By G. W. C. KAYE, O. B. E., M. A., D. Sc., The National Physical Laboratory, and T. H. LABY, M. A., Professor of Natural Philosophy, The University of Melbourne. Longmans, Green and Company, 39 Paternoster Row, London; Fourth Avenue and 30th Street, New York; Bombay, Calcutta and Madras. 1921. iii + 161 pp. 16.5 × 25 cm. Price \$4.00.

The selection of data to be included in a small handbook of convenient size and moderate price to be used both by physicists and chemists is a difficult problem. The fact that a fourth edition of these Tables, first published in 1911, has now appeared is evidence that the selection there made was a wise one. Nevertheless, the Tables are much more complete from a physical than from a chemical standpoint. For instance, information as to chemical equilibria, electromotive forces, the vapor pressures of solutions, and reaction velocities is almost wholly lacking. We are sure that a still wider usefulness for the book could be secured by a revision and extension of its chemical data.

A number of alterations and additions have been made in this issue. Matter relating to the figure of the earth, the absolute determination of the acceleration of gravity, and more extended tables of the relative value of that constant have been added. The chemical data have been recalculated, using the international atomic weights. Some 700 additions and alterations in the physical constants of chemical compounds have been made. The authors state that the published values of these constants have been critically examined, and what appear to be the more accurate values for the chemical compounds included in these pages, have been used. Many of the heat tables have also been revised and amplified. The modernity of the book is demonstrated by the addition of tables of atomic

numbers, spark-gap voltages, X-ray wave lengths and terrestrial magnetic constants. The effect has been to increase the size of the book by 8 pages.

All told, this book represents a surprisingly complete and satisfactory collection of natural constants in a small bulk and a convenient form. It is unfortunate, but doubtless unavoidable, that the price has been fixed at nearly three times as much as that of the first edition.

ARTHUR B. LAMB.

**The Principles of the Phase Theory.** By DOUGLAS A. CLIBBENS, PH. D., Lecturer in Inorganic and Physical Chemistry in the University of London, King's College. Macmillan and Co., Limited. St. Martin's St., London, 1920. xx + 383 pages. 15 × 22.5 cm. Price \$10.00.

The title of this book, "The Principles of the Phase Theory" is misleading. Not only is there no discussion of the fundamental thermodynamic principles which underlie that portion of the study of heterogeneous equilibrium usually treated under the Phase Rule, but also there is no suggestion that there are such fundamental principles. The subtitle, "Heterogeneous Equilibrium between Salts and their Aqueous Solutions" is more truly descriptive, and the book will prove useful to those interested in this particular portion of the application of phase theory, and restricted to English texts.

The reviewer cannot agree with the author that "... a thorough study of the condensed system offers the easiest path to a true understanding of the methods of the Phase Theory," and believes that the reader who is unfamiliar with the subject, for whom the book is avowedly written, would have a clearer grasp of the equilibrium relations in systems in which hydrates are formed if the changes in pressure in the various univariant systems were coördinated with the changes in temperature and composition. The author frequently finds it necessary to disregard this limitation to condensed systems; for example, in order to explain the important process of isothermal evaporation. This process, as well as the relation of the condensed system to the isobaric saturation curve, would be understood more easily if a few isobars were included.

The chapters deal with condensed binary, ternary, quaternary and quinary systems, and the concluding chapter with graphical methods. The author does not have the gift of clear exposition, and devotes many pages to the detailed discussion of obvious geometrical relationships. The entire chapter on ternary systems is an example. It is hard reading, even for one familiar with, and interested in, the subject, and could be improved by elimination of much of the detailed discussion. The final chapter on graphical methods seems redundant. Its material either has been, or should have been, treated in preceding chapters, so that it becomes merely a further exercise in geometry. Indeed, to the reviewer it seems that this book carries to an extreme the too common tendency of writers on Phase

Rule to devote much space to geometry, without giving a hint as to the thermodynamical justification of the geometry. The paucity of literature references is surprising.

GEORGE W. MOREY.

**Allgemeine Photochemie. General Photochemistry.** By PROF. DR. phil. et chem. J. PLOTNIKOW, Director of the photochemical Research Laboratory at the Aktiengesellschaft für Anilinfabrikation Berlin-Treptow; o. Prof. and Direktor of the Chemischen Instituts at the former Kaiserlichen Universität at Moscow. Walter de Gruyter and Company, Berlin and Leipzig. 1920. 729 pp. 68 fig. 24 X 16 cm. Price \$7.00.

According to the preface of this book, the author, a Russian recently domiciled in Germany, began 10 years ago to write a complete encyclopedic handbook of photochemistry, but the political upheaval in Russia and his personal misfortunes prevented the full attainment of this end and he has had to be content with this volume of 700 odd pages, which in the subtitle he describes as a hand- and text-book, for the research, study and practice of photochemistry.

Irrespective of the book itself, this preface will command the interest and sympathy of future generations of students of photochemistry. It tells how the author, formerly Professor at and Director of, the Chemical Institute at the Imperial University of Moscow, began to write this book in the summer of 1917 on his country estate in the province of Riasau in Russia. The revolution started; day after day he saw the followers of Kerensky plunder and destroy the farm and estate to whose development he had devoted years of effort. His country library was destroyed in order to manufacture cigarettes! Then came the Bolshevik outbreak and he was obliged to flee to Moscow where only by selling his furniture and his scientific library, book by book, could he keep his family and himself from starvation. Finally even these means failed, and he and his family made their way to the Ukraine, but he was soon forced to flee from this refuge, at last reaching Germany in 1918, where he found assistance and relief among his scientific and industrial friends. During all this time he kept working on his book and succeeded in getting the manuscript safely to Germany and completing it there.

The book is divided into four parts. The first part, introductory in nature, discusses photochemical valence and the sensitivity of substances to light; states the fundamental laws of photochemistry, discussing the influence of temperature on the photochemical processes; classifies light reactions and gives a short tabular statement of the historical development of the subject.

The second part discusses the practice and theory of photochemical kinetics, catalysis and equilibria. The discussion of the practice or technique is brief, since this has been covered fully in the author's earlier

volume on that subject. The discussion of the mathematical theory is based largely on the author's independent development of his own theoretical views.

The third part, which constitutes the bulk of the book, is a detailed catalog and discussion of all the more important known photochemical reactions. Inorganic and organic reactions are discussed separately; those in the former group being classified according to the significant elements arranged in the order of the periodic system.

The fourth part of the book is devoted to the applications of photochemistry, chiefly photography of course, and this is by far the most sketchy and unsatisfactory part of the work.

The book as a whole will surely be of great usefulness to the students and investigators of photochemical subjects. It is impossible to form any judgment as to the permanent value of the theoretical treatment, but it cannot but be stimulating. The unified treatment of the whole subject, and the collection of photochemical reactions are certain to be valuable. The book suffers from too subjective a point of view. This is brought out perhaps too emphatically by the observation that in his tabulation of important events in the recent history of photochemistry only five entries since 1915 appear; they all refer to publications by the author, the present volume representing the culmination. Certain important aspects of the subject have also been given far too scanty attention. Thus the recent work of Marcelin and of W. C. M. Lewis is not mentioned; that of Perrin is dismissed with four lines of discussion.

Whoever reads the preface cannot, however, but view these blemishes with understanding and sympathy.

ARTHUR B. LAMB.

**Die Welt der vernachlässigten Dimensionen.** By WOLFGANG OSTWALD. Fifth and sixth editions. Theodor Steinkopff, Dresden and Leipzig, 1921. pp. xii + 253. 23 × 16 cm. Price 7 shillings.

The fourth edition was sold out in six months and we now have the fifth and sixth editions simultaneously, which seems a contradiction in terms. Merely as a matter of curiosity one would like to know how many editions can be issued simultaneously. Perhaps the author uses editions and thousands synonymously.

The author believes that this continued demand means that the book has become, or is going to become, an "Introduction to Colloid Chemistry." The reviewer does not quite see how a book which is in the form of lectures delivered in the winter of 1913-14 can be kept in that form and also up to date. The size of the book has increased 32 pages.

WILDER D. BANCROFT.

**Oedema and Nephritis.** A Critical, Experimental and Clinical Study of the Physiology and Pathology of Water Absorption in the Living Organism. By MARTIN H. FISCHER, M. D., Eichberg Professor of Physiology in the University of Cincinnati. Third and enlarged edition. John Wiley and Sons, Inc., New York; Chapman and Hall, Limited, London, 1921. xvi + 922 pp. 217 fig. 15.5 × 23.5 cm. Price \$10.00 (60s. net).

As the author informs us in the preface, he has left this third edition virtually unaltered in respect to every statement contained in the two preceding. He has, however, made a number of additions. These comprise a more detailed development of the concept of the hydrophilic colloid, observations on the swelling of aleuronat, further experiments on the swelling of gelatin in non-acid media, a discussion of the nature of the increase and decrease in hydration capacity of the proteins, a more extensive presentation of the author's conception of secretion, experimental evidence regarding the distinction between swelling and "solution" of colloids and on the behavior of proteins in the presence of buffer mixtures, renewed emphasis on the non-relationship, as the author holds, between disease of the kidney and the generally accepted signs, symptoms and complications of nephritis, additional suggestions regarding the treatment of nephritis, and an even more positive insistence upon the purely infectious origin of vascular disease and chronic interstitial nephritis.

In brief this book deals in very striking fashion with the bearings of colloid chemistry upon the problems of the relations of water to living matter. Its arrangement and printing are excellent, and its literary style clear, interesting and forcible, especially forcible for the author states his views with overwhelming positiveness. The polemical tone is doubtless in part at least a reaction to the acerbity with which some of Fischer's theoretical ideas were attacked and his practical deductions combated when first presented. But even his critics must concede that he was in many points essentially right, and that he was one of the first investigators to recognize the important part which, as nearly everyone now realizes, is played by the colloidal properties of living matter. Fischer may justly complain of the way in which certain methods of treatment (*e. g.*, sodium hydrogen carbonate for acidosis, and gum-saline after hemorrhage) which were criticized as unsound when presented by him some years ago have recently been brought forward by others without adequate credit to him who first suggested them. The reviewer once heard one of Fischer's critics state in a discussion before a scientific assembly that he, the critic, "refused to muddy his thoughts with colloids". Fischer has thrown much light upon a "muddy" field.

On the other hand, the tenacity with which Fischer defends every detail of any position which he has once taken must be admitted as a marked defect in this work. Even admitting that the author's own ideas were originally completely correct and may now be reprinted verbatim, it is

doubtful whether he himself would hold that the entire general background of information available in the literature when he first wrote was correct. Some of the work of others which he quoted as affording foundation and background for his own work must have been partly erroneous or now need re-interpretation. For example, it is highly probable now that the only acid which ever occurs free in any appreciable concentration in a living tissue is carbonic acid.

In the next edition of this work the leading rôle may well be taken with ever increasing confidence by colloids, but many of the conceptions which were generally prevalent, but vague or incorrect, a decade ago should now be discarded, and the author's own work should be presented against a background newer and more specific.

YANDELL HENDERSON.

**Lehrbuch der Cellulosechemie.** Für Studierende an technischen Hochschulen und Universitäten sowie für Cellulose-Fachleute. BY DR. EMIL HEUSER, a. o. Professor of Cellulosechemie at the Technischen Hochschule at Darmstadt. Gebrüder Borntraeger, Berlin, 1921. vii + 188 pp. 3 figs. 16.5 × 25.5 cm. Price M 32.

The volume, as stated in the introduction, has been written in response to a long felt need on the part of students of chemistry, paper-making, textile chemistry and related subjects, no book having hitherto been published on this subject. According to the author such a work should contain a brief, critical review of the important experimental facts and their bearing on the problem of the constitution of cellulose.

The difficulties surrounding the presentation of such a complex subject as cellulose chemistry have been satisfactorily overcome by a division of the subject under the six headings of (A) Alkali Cellulose, (B) Ester Formation, (C) Ether Formation, (D) Oxidation, (E) Decomposition Reactions, and (F) Constitution, each of which has been handled in a critical and illuminating manner. The treatise seems to be noticeably free from printer's errors. "Triglukose," p. 76, should evidently read "Trimethylglukose."

So marked is the present activity of scientific workers on the subject of the constitution of cellulose that the last chapter will probably stand in need of early revision.

The volume can be heartily recommended to all students of chemistry and especially to those interested in commercial progress in the field of cellulose products. No technical chemist can afford to disregard the scientific work at present being carried out in the various countries relating to the constitution of cellulose, for in the acquirement of this knowledge lies the surest road to new developments and progress in all branches.

STUDIES ON SOLUBILITY. III. THE SOLUBILITY OF METAL  
AMMONIA SALTS IN SALT SOLUTIONS.

By J. N. BRÖNSTED AND AGNES PETERSEN.

Received April 4, 1921.

Introduction.

In two previous papers<sup>1,2</sup> one of the writers has given views on the treatment of solubility equilibria, involved when salt solutions are employed as solvents for salts. To illustrate the scope of these views a few results were communicated from an extensive series of experimental determinations on solubility, dealing mainly with solubility of metal ammonia salts in solutions of other salts. In this and later articles a more complete statement of the data procured and of additional experiments will be given.

The employment of metal ammonia salts is specially fitting for the purpose of studying the laws of solubility. They are in general really strong electrolytes, and for the most part not liable to hydrolysis of any kind. On account of the great number of cations and anions belonging to this group the number of salts it contains is extremely high. The solubility is usually small, and salts of a solubility between 0.01 and 0.0001 molal,

<sup>1</sup> Brönsted, *THIS JOURNAL*, 42, 761 (1920).

<sup>2</sup> *Ibid.*, 42, 1448 (1920).

the most convenient range of concentration for the theoretical and experimental treatment, can be prepared easily, abundantly and usually in a very pure state. Finally, and this point is not to be undervalued, the determinations of solubility can for all compounds of this type be carried out uniformly, namely by decomposing with alkali, with or without addition of reducing substances such as stannous chloride, by simply estimating the ammonia liberated by adsorption in sulfuric acid, using methyl red as an indicator.

A number of the salts employed for our investigations have been described before in the publications of the leading authors in this domain, S. M. Jørgensen and A. Werner. A good many, however, have been produced for the first time by us. As in all such cases the constituent ions were well known, we have confined ourselves to an analysis of their ammonia and water contents. In order to secure the high purity which was essential, the whole sample of each salt was stirred repeatedly with fresh portions of water till a constant solubility was found. The salt was considered pure when this constant value agreed with that found when using only a small quantity of salt for solution.

Fig. 1.

The temperatures of the experiments were  $0^{\circ}$  and  $20^{\circ}$ . Determinations were made on a number of salts at both temperatures, whereby the important figures for the temperature coefficient, to be considered later, have been obtained. The praseo salts are the most unstable within the range of compounds employed and could not be studied at  $20^{\circ}$ ; but other salts are also transformed in solution and so give solubility values, which slowly increase with the time, especially at  $20^{\circ}$ . As the velocity of solution for a metal ammonia salt is generally rather high such slow transformations were usually no hindrance in our determinations.

The determinations at  $20^{\circ}$  were carried out in an ordinary thermostat, regulating to within  $\pm 0.01^{\circ}$ . The apparatus employed for the measurements at  $0^{\circ}$  is shown in Fig. 1. When saturation had taken place a known volume of the saturated solution was sucked out through a small cotton plug, and the determination of the concentration made as described above.

In judging the accuracy reached by our measurements we must distinguish between relative and absolute exactness. When a series of ex-

periments is carried out with the same sample of salt using the same acid for estimation and working under the best conditions obtainable, the possible relative error in the determinations will hardly reach some tenths of a per cent., and the possible absolute error 1%. Especially in that part of our data which was first obtained and most of which appears in the first part of the tables following the accuracy is probably considerably lower.

In carrying out these determinations we were valuably assisted by cand. polyt. Max Möller, and cand. polyt. E. Smith-Jensen to whom the writers wish to express their best thanks. We likewise wish to express our indebtedness to Carlsbergfonden for subsidizing the work.

### I. Solubility of Metal Ammonia Salts in Water.

We shall first give a survey of the metal ammonia ions, and others, constituting the salts employed in our determination. The names, formulas and valences of the ions used, are given below.

Ion.	Formula and Valence.

The following table records the solubilities of salts formed by these and more usual cations and anions, using pure water as solvent.

In all cases when not otherwise especially indicated, the figures for solubilities and concentrations mean molal concentrations; for luteo sulfate, for example, the number of molecules of  $[\text{Co}(\text{NH}_3)_6]_2(\text{SO}_4)_3$  in one liter of the solution. The abscissas of the figures are in equivalents of added salt per liter.

## II. Uni-univalent Salts in Uni-univalent Solvents.

With most of the uni-univalent salts specified in the foregoing section, determinations have been carried out using as solvents salt solutions of various concentrations. In a previous paper the following equation was found to indicate the change in solubility with the concentration, based

$$\log \frac{s}{s_0} = a(\sqrt[3]{c_i} - \sqrt[3]{s_0})$$

on the assumption of Noyes and Falk<sup>3</sup> of the equality of the activity coefficients and the validity of the expression for the lowering of the freezing point.

The experimental results are given in the following tables. The value of the coefficient  $a$ , which may be calculated according to the above equation for each concentration of the solvent  $c = c_i - s$  is also given in the tables to show the validity of the underlying assumptions.

The first data are those of certain praseo cobaltic salts. As mentioned above, the praseo salts are rather unstable in aqueous solutions, owing to the progress of the reaction

easily observable through the change in color of the solution from green to red. This reaction takes place rapidly at 20°, and constant figures are therefore not to be obtained at this temperature. At 0°, when the time of stirring varies, no appreciable change in solubility is observed within 5 to 10 minutes. As the salts dissolve very quickly, reliable results can be obtained at this temperature. The figures at least will be mutually comparable even when the absolute values may be somewhat more uncertain here than in most other cases.

<sup>3</sup> Noyes and Falk, *THIS JOURNAL*, 32, 1011 (1910); 33, 1436 (1911); 34, 454, 458 (1912).

For the calculation of  $s/s_0$  in the last four solvents the value  $s_0 = 0.00283$  was used as found in this series of experiments. The value of  $a$  for sodium chlorate becomes a little greater than that given in the previous paper (0.30).

Experiments were also made with praseo nitrate in potassium and sodium chlorate solutions, but the increase in solubility is here much smaller than in the case of other solvents. Moreover the values were found to decrease with increasing time of stirring. Some special reaction must here evidently take place.

Inspection of the data in Tables II and III shows that the solubility of the two salts concerned increases with increasing concentration of the solvent, in all cases in close analogy to what has been stated in the previous article. The values of  $a$  for any solvent show a marked agreement and approximation to the value  $1/3$ . For the calculation of the mean of the values of  $a$ , the solutions stronger than 0.1 molal, for which the solubility equation at any rate does not hold good, and the most diluted ones, in which the experimental error has too great influence, have been excluded. In these and subsequent tables  $t = 0^\circ$ , except when otherwise indicated.

With praseo bromide in addition to salt solutions both acetic acid and the three-chloro-acetic acids have been used. The incomplete dissociation of these acids is very markedly proved in the values of  $s/s_0$  and  $a$ . While for all salt solvents the calculated normal values of  $a$  are in the neighborhood of 0.3, using these acids we find that increasing concentration is accompanied by a rapid decrease in this coefficient. This phenomenon is extremely pronounced with the weak acetic acid, but also the substituted

acid and even the trisubstituted acid show similar behavior. This indicates that not even trichloro-acetic acid is a really strong electrolyte.

The croceo cobaltic salts are rather stable in solution and give as a rule easily reproducible values for their solubilities. Some of the figures for croceo nitrate stated below have been communicated in an earlier paper,<sup>4</sup> where the existence of two modifications, an  $\alpha$ - (unstable) and a  $\beta$ -modification (stable), was indicated.

We find again constant values for  $a$  when potassium formate is used as a solvent, while potassium thiocyanate gives increasing values. Special attention should be called to the behavior of potassium hydroxide as solvent. We find here an increase in the solubility only with the most diluted solution. At higher concentrations it falls very markedly, indicating a specific effect of the solvent. To explain the phenomenon we imagined the possibility of a separation of croceo hydroxide in the solid state. On adding a solution of molal sodium hydroxide to a solution of croceo nitrate or croceo chloride, we indeed observed the appearance of a crystalline precipitation of a sparingly soluble compound. This proved, however, to be croceo carbonate, and does not appear when using pure solutions. As solubility measurements are carried out with an hydroxide entirely free from carbon dioxide, the explanation of the phenomenon is not to be found here. It may be due to a special reaction between the solvent and the saturating salt, or it may be looked upon as a peculiarity of the solvent, manifesting itself through an exceedingly great "salting out" effect. Of course, merely using this expression does not explain the phenomenon. However, it is sufficient to place it in that great field of phenomena which are of deep significance in connection with the theory of solubility and with which we will deal more thoroughly in subsequent articles.

<sup>4</sup> *Meddel. K. Vetenskapsakad. Nobelinstit.,* 5, 25 (1919).

When using potassium and sodium chloride solutions as solvents, other peculiarities were noted. The increase in solubility of croceo nitrate is found to be much less than otherwise, for example with 0.1 *N* solutions at 0° for potassium chloride, 1.16; and for sodium chloride, 1.14. This phenomenon was also studied by using mixed nitrate and chloride solutions as solvent and will be discussed more thoroughly when the question of such mixed solvents is taken up.

The figures in Tables IX, X and XI show values of *a* which are rather variable when the concentration changes. This is especially noteworthy

in the instance of the dioxalo-triammine cobaltiate. The rise in solubility is here much greater than usual.

In Table XII are given the figures obtained with croceo chloride, the most soluble of the croceo salts employed.

Further measurements were carried out with oxalo-tetrammine cobaltic salts. These are stable in solution, but it is more difficult to produce them in a quite pure state than the croceo salts. The data given in Tables XIII, XIV, XV and XVI will therefore scarcely possess the same degree of accuracy.

Thallous tetranitro-diammine cobaltiate, with which salt a series of measurements was also carried out, showed surprisingly small increases in the solubility, as indicated in Table XVII. The small solubilities in potassium salt solutions are probably due to the formation of a solid mixture of thallous and potassium tetranitro-diammine cobaltiate.

The mean value of all these figures is  $a = 0.31$ , which is in accordance with the  $a$ -value derived from the freezing-point measurements as shown in the previous paper. Inspection of Table XVIII and the foregoing tables shows, however, that we cannot count upon constant  $a$  values, even if one salt is considered in connection with different solvents, or what was

more probable, when one solvent is considered in connection with different salts. There is, however, an important regularity to which attention must be called. When a solvent proves of greater dissolving power in one instance, it seems to prove so in all. We see, for example, that potassium salts have a greater dissolving effect than sodium salts, chlorates than chlorides, and these again than formates, etc. With a single exception, that of praseo nitrate in potassium formate solution, the sequence of solvent power for all of the salts for which sufficient data have been procured, is as follows: potassium chlorate, sodium chlorate, potassium chloride, sodium chloride, potassium formate, sodium formate.

This sequence is observed not only with uni-univalent salts, with which we are dealing, but also with salts of other types, and especially when non-electrolytes are considered. We shall in a later paper deal more in detail with this fact, which is of high importance for our conception of electrolytic solution. The sequence also, as far as reliable data are available, is coincident with that obtained by ranging the salts according to their freezing-point lowering. Of all salts employed, potassium nitrate showed the slightest lowering of the freezing point and at the same time produced the greatest increase in solubility. From both of these facts we infer that the activity coefficients of univalent ions have smaller values here than in the other solvents employed. Sodium formate on the other hand shows large values for the freezing-point lowering and correspondingly less solvent power than the other salts. At any rate these are phenomena to be duly regarded as derived from a rigid relation between osmotic and activity properties of solutions.

It cannot, however, be denied, that really constant  $\alpha$  values are not obtained in most cases, even with very sparingly soluble salts. We can imagine that the incompleteness of our hypothesis is the reason for such deviations. It is true that the secondary electric effect spoken of in the previous paper may influence the activity to a considerable extent, even with univalent ions. On the other hand the cube root expression of Noyes and Falk,<sup>3</sup> underlying our calculation of the  $\alpha$  values, certainly gives no exact representation of the freezing-point curves, as illustrated in a recent publication of G. N. Lewis and G. A. Linhart,<sup>5</sup> and many discrepancies may be due to this fact.

The equation found by Lewis and Linhart, claimed by them to be of universal validity, is

$$\log \left( n\lambda - \frac{\theta}{c} \right) = \alpha \log c + \log \beta, \quad (1)$$

where  $n$  is the number of ions formed by one mol of salt on complete dissociation,  $\lambda$  the theoretical molecular freezing-point lowering (1.858°),  $\theta$

<sup>5</sup> Lewis and Linhart, *THIS JOURNAL*, **41**, 1951 (1919).

the lowering found,  $c$  the concentration and  $\alpha$  and  $\beta$  constants. The equation may also be written,

$$\Delta = \Delta_0 - \beta c^\alpha, \quad (2)$$

where  $\Delta$  and  $\Delta_0$  indicate the molal lowering observed and calculated, respectively.

In the first two columns of Table XIX are given the values of  $\alpha$  and  $\beta$  for a number of salts calculated by Lewis.

TABLE XIX.

	$\alpha$ .	$\beta$ .		$\alpha$ .	$\beta$ .
KCl	0.535	1.223	K <sub>2</sub> SO <sub>4</sub>	0.374	3.187
NaCl	0.535	1.223	BaCl <sub>2</sub>	0.364	2.660
KIO <sub>3</sub>	0.442	1.196	CoCl <sub>2</sub>	0.362	2.456
NaIO <sub>3</sub>	0.442	1.196	Mean	0.37	2.7
Mean	0.49	1.21	MgSO <sub>4</sub>	0.293	3.404
			CdSO <sub>4</sub>	0.325	4.421
			Mean	0.31	3.9

In the last two columns we have added the mean values of  $\alpha$  and  $\beta$ . According to these figures it seems that the  $\alpha$ -values decrease, and the  $\beta$ -values increase, by increasing valences of the ions.

The term  $\gamma = \frac{x}{c}$ , called by Lewis the thermodynamic or corrected degree of dissociation, is the same as the activity coefficient  $f$  used throughout the previously mentioned papers. Equation 17 in Lewis' paper expressing the relationship between activity coefficient and concentration is easily reached by introducing the osmotic coefficient,

$$\varphi = \frac{\Delta}{\Delta_0}, \quad (3)$$

and the relation between this and the activity coefficient,

$$c \frac{d \ln f}{dc} = c \frac{d\varphi}{dc} - (1 - \varphi). \quad (4)$$

Substituting here from Equation 2

$$\varphi = 1 - \frac{\beta c^\alpha}{\Delta_0}$$

and hence,

$$\frac{d\varphi}{dc} = -\frac{\beta}{\Delta_0} \alpha c^{\alpha-1}$$

We then find,

$$\ln f = -\frac{\beta(1+\alpha)}{\Delta_0 \alpha} \cdot c^\alpha \quad (5)$$

which is identical with Equation 17 of Lewis and Linhart.

In the case of saturation of a binary salt in a binary hetero-ionic solvent we have, when  $s$  indicates the solubility,

$$sf = \text{Const.}$$

or

$$\log s = \frac{\beta(1 + \alpha) c^\alpha}{2.303 \Delta_0 \alpha} + \text{const.} \quad (6)$$

Introducing for the solubility in pure water,

$$\log s_0 = \frac{\beta(1 + \alpha) s_0^\alpha}{2.303 \Delta_0 \alpha} + \text{const.,}$$

and putting

$$\frac{\beta(1 + \alpha)}{2.303 \Delta_0 \alpha} = L \quad (7)$$

we obtain

$$\log \frac{s}{s_0} = L \cdot c^\alpha \quad (8)$$

Inserting in (7) and (8) the values of  $\alpha$  and  $\beta$  for potassium chloride we find,

$$\log \frac{s}{s_0} = 0.41 c^{0.535}; \quad (8a)$$

and for potassium iodate,

$$\log \frac{s}{s_0} = 0.456 c^{0.442}; \quad (8b)$$

and for magnesium sulfate,

$$\log \frac{s}{s_0} = 1.76 c^{0.293}. \quad (8c)$$

Using the formula given by Noyes and Falk for the freezing-point lowering we have found as shown in the foregoing paper

$$\log \frac{s}{s_0} = a c^b \quad (9)$$

where  $a$  and  $b$  are constants, an expression of the same form as that reached by means of the equation of Lewis. There is however a considerable difference between the constants in the two formulas. While in the case of uni-univalent salts  $L$  and  $\alpha$  both have values in the neighborhood of 0.4–0.5,  $a$  and  $b$  are both equal to  $1/3$ . For magnesium sulfate the difference lies in the same direction. It is remarkable however that the solubility curve of xantho chromate in magnesium sulfate calculated in

the foregoing paper according to Formula 9, gives a rather close agreement with (8c) since we have here,

$$\begin{array}{ll} L = 1.76 & a = 1.80 \\ \alpha = 0.293 & b = 0.333. \end{array}$$

### III. Uni-univalent Salts in Solvents of Other Types.

A small number of experiments has been made to find the influence of the type of the solvent upon the solubility of uni-univalent salts. The results of these experiments are given in the following tables.

TABLE XX.—PRASEO

H <sub>2</sub> O		78.9	

TABLE XXIV.—CESIUM TETRANITRO-DI-  
AMMINE COBALTIATE.

Solvent.	$c$ .	$s \times 10^4$ .	$s/s_0$ .
NaOOCH	1	785	1.47
NaNO <sub>3</sub>	1	1268	2.38
Mg(NO <sub>3</sub> ) <sub>2</sub>	0.5	1113	2.09
MgSO <sub>4</sub>	0.5	815	1.54
H <sub>2</sub> O		532	

Comparing the data from these tables with those found for the same salts in uni-univalent solvents, we find that as a rule the solubility is mainly governed by the equivalent concentrations of the solvent, independent of its type. A solution of magnesium sulfate or of sodium oxalate dissolves just as much as a solution of a uni-univalent salt of the same equivalent concentration. The agreement between the figures is at any rate probably sufficient for establishing this rule as general, the deviations being of the same order of magnitude as found when uni-univalent solvents are mutually compared.

The values from Tables XXIII and XXIV show great diversity owing to the high concentration of the solvent employed, whereby the secondary effects are greatly increased. However, no systematic distinction between solvents of different types can be observed in these cases, either.

Because of the character of the systems no  $a$  values can be calculated here.

## IV. Bi-bivalent Salts in Bi-bivalent Solvents.

Six systems of this type have been examined. The results are given in the tables below.

				<u>3.3</u>

The *a* values are calculated according to the same equation as used in uni-univalent salts,

$$\log \frac{s}{s_0} = a (\sqrt[3]{c} - \sqrt[3]{s_0}).$$

For all the *c* and *s* calculations molal concentrations are used. The average *a* values of the first three systems, 1.71, is somewhat more than four times the *a* values for uni-univalent systems, corresponding to curves that rise much more precipitously than in the case of uni-univalent systems.

Using equivalent concentrations instead of molal concentrations in the equation we find  $a = 1.38 = 4 \times 0.34$ , instead of  $a = 1.71$ .

The three oxalates afford a very much higher increase in solubility than the other bi-bivalent salts, and correspondingly higher  $a$  values, about 3.4.

### V. Bi-bivalent Salts in Solvents of Other Types.

Bi-bivalent salts have also been determined by employing uni-uni- and uni-bivalent solvents. The results are given in Tables XXXI-XXXVI.

TABLE XXXI.—CHLORO-PENTAMMINE COBALTIC HEXACHLOROPLATINATE.

A glance at these tables and the tables in the foregoing section shows first, much more precipitous curves than found with uni-univalent solvents; second, that the rule of the equal action of equivalent normal solutions, found to hold for uni-univalent solutes, does not hold when the solute contains bivalent ions. It is evident, as appears in Fig. 2 representing the curves of solubility of xantho chromate, that a solution of a bi-bivalent

salt, such as magnesium sulfate, dissolves considerably more of the bivalent solute than does an equally strong solution of a uni-univalent salt, such as potassium formate or sodium chloride. From this we can

Fig. 2.—Solubility ratio  $s/s_0$  for xantho chromate in (1) NaOOCH and NaClO<sub>3</sub>, (2) NaCl, (3) KClO<sub>3</sub>, (4) NaNO<sub>3</sub>, (5) KNO<sub>3</sub>, (6) KOOCH, (7) KCl, (8) MgSO<sub>4</sub>. draw the conclusion that in an equal equivalent concentration of the solvent the activity coefficient of a univalent ion present in the solution is influenced to a smaller extent than is the activity coefficient of a bivalent ion. The significance of this conclusion will be clearer when considering solutes composed of ions of different valences. This is treated in the following section.

## VI. Uni-bivalent Salts in Solvents of Various Types.

The first measurements were carried out with uni-univalent solvents alone. The data are as follows.

The data represented in Figs. 4 and 5 show a somewhat stronger increase with increasing concentration of the solvent than in the case of uni-univalent salts. Otherwise the curve is almost the same, particularly as to the order of the various solvents with regard to dissolving power.

Three other salt determinations were carried out using solvents of higher types. The results from these are given in Tables XLI-XLIII and in Figs. 6, 7 and 8.

In describing the phenomena appearing in these systems it is necessary to make a sharp distinction between two cases of interaction of uni-bivalent salts. In the first of these the two salts are electrically isotypic, as for example chloropentammine bromide and calcium formate  $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Br}_2$  and  $\text{Ca}(\text{OOCH})_2$ ; and in the other they are electrically heterotypic, as for example croceo sulfate and magnesium chloride,  $[\text{Co}(\text{NH}_3)_4(\text{N}-\text{O}_2)_2]_2\text{SO}_4$  and  $\text{MgCl}_2$ .

Fig. 5.—Solubility ratio of bromopentammine chloride in (1)  $\text{NaClO}_3$ , (2)  $\text{KClO}_3$ , and of thiocyanate pentammine iodate in (3)  $\text{NaOOCH}$ .

When a uni-bivalent isotypic solvent is employed, the solubility of the salt does not increase any more than when a uni-univalent one is employed. Potassium dichloro-acetate and calcium formate dissolve chloropentammine cobaltic bromide to nearly the same extent. Sodium oxalate and potassium chloride dissolve equal amounts of croceo sulfate. On the other hand using an electrically heterotypic solvent we find much greater solubilities, nearly the same as when bi-bivalent solvents are employed.

From these results and those previously given we are justified in concluding that the activity of an ion is affected similarly by ions of the same sign, only when the equivalent concentration of the acting ions is the same. If the dissolved ion is uni-univalent the action of ions of the opposite sign will likewise depend chiefly upon the equivalent concentration. In the case of dissolved ions of higher valence than unity, the effect of the ion of opposite sign will increase with increasing valence. In all cases the activity of an ion depends much more upon the nature

Fig. 4.—Solubility ratio of bromopentammine bromide in (1)  $\text{KOOCCl}_4$ , (2)  $\text{NaOOCH}$ , (3)  $\text{KOOCH}$ , (4)  $\text{NaClO}_3$ , (5)  $\text{KClO}_3$ .

of the solvent. When a uni-bivalent heterotypic solvent is employed, the solubility of the salt does not increase any more than when a uni-univalent one is employed. Potassium dichloro-acetate and calcium formate dissolve chloropentammine cobaltic bromide to nearly the same extent. Sodium oxalate and potassium chloride dissolve equal amounts of croceo sulfate. On the other hand using an electrically heterotypic solvent we find much greater solubilities, nearly the same as when bi-bivalent solvents are employed.

of the ions of the opposite sign than on that of the ions of the same sign, a point of view of importance in the general conception of salt solutions.

The curves are shown in Figs. 9, 10, 11 and 12. In the case of luteo-tetranitro-diammine cobaltiate we encounter the same effect of the electric type of solute and solvent as in the case of uni-bivalent salts, but to a still more marked degree. When the solvent contains bivalent anions the solubility is increased very much more than when it contains bivalent cations, in accordance with the principle developed in the foregoing section.

Roseo-tetrathiocyanato chromiate exhibits the same behavior towards solvents of different electrical type. Here, however, the individual influence of the solvents proves to be more marked. Only the curves for magnesium chloride and potassium chloride are nearly coincident.

The diagrams for the two salts with trivalent anions show this less conspicuously. The greater dissolving power of the bivalent cation as compared to the bivalent anion is still noticeable but only in the most diluted solutions. With rising concentration the individual nature of the solvent seems to play a considerable part in the action, obscuring to a certain degree the pure primary electrical effect. The diagram of praseo-hexacyano ferriate is particularly difficult to account for from the point of view adopted here. On account of the instability of the saturating salt the data are probably not very reliable.

In this series the increase in solubility is very much higher than in the foregoing, as shown in Table XLVIII-L, and the accompanying diagram.

Fig. 13.—Solubility ratio of luteo hexacyano cobaltate in (1)  $\text{NaOOCH}$ , (2)  $\text{KOOCH}$ , (3)  $\text{NaCl}$ , (5)  $\text{KCl}$ , (7)  $\text{MgSO}_4$ , and of luteo hexacyano ferriate in (4)  $\text{KCl}$ , and of luteo trioxalo cobaltate in (6)  $\text{NaCl}$ .

salt, indicating that the solubility increases more than in proportion to the increase in the concentration of potassium chloride.

Magnesium sulfate again gives sharply rising solubility curves for tri-

<sup>6</sup> An attempt was made to determine the solubility of luteo-trioxalo cobaltate in  $\text{KCl}$  solution as well. While with  $\text{NaCl}$  as solvent, green solutions are obtained, the color of which is due to the  $\text{CoOx}_3^{---}$  ion,  $\text{KCl}$  gives yellow solutions evidently not containing the complex ion. The phenomenon is explained by assuming the existence of the double salt:  $\text{K}_2[\text{Co}(\text{NH}_3)_6][\text{Co}(\text{C}_2\text{O}_4)_3]_2 \cdot 6\text{H}_2\text{O}$  described by S. P. L. Sørensen ("Studier over Koboltidoxalater," Copenhagen, 1899, p. 71). As no corresponding sodium double salt is formed under the same condition and the potassium salt is very sparingly soluble, this peculiar reaction probably could be used for the separation of the two alkali metals.

<sup>7</sup> The agreement in properties of salts of the ions  $\text{Co}(\text{CN})_6^{---}$  and  $\text{Fe}(\text{CN})_6^{---}$  are well-known. It is probable, however, that a careful scrutiny will show much more concordance than hitherto assumed. According to Werner's theory, we have in both cases in octahedral arrangement of  $\text{CN}$  groups around a central  $\text{Co}$  or  $\text{Fe}$  atom. Just as with the nucleus in isotopic atoms, the central atom in these groups is shielded from reaction with outside atoms or groups if the distances between the central atom and the coordinated groups are the same. The figures for the specific weight of  $\text{K}_2\text{Fe}(\text{CN})_6$  and  $\text{K}_2\text{Co}(\text{ON})_6$  prove that this holds very approximately, the distances in the  $\text{Fe}$  compound exceeding those in the  $\text{Co}$  compound by less than 2%.

The curves for luteo-hexacyano cobaltate and ferriate exhibit a remarkable concordance, and the absolute solubilities are also very nearly the same.<sup>7</sup>

Also the shape of the solubility curve of the trioxalo cobaltate shows a close agreement with that of the cyanides. The first mentioned curve is however steeper, showing that the activity of the trioxalo cobaltate ion is lessened by the solvent more than is the activity of the two others.

A saturated solution of luteo hexacyano cobaltate in 3 *N* potassium chloride solution gives on dilution with water to 0.5 *N* in a short time a precipitate of the solid luteo

trivalent salts. In 0.1 *M* solution the solubility of luteo-hexacyano cobaltate is 40 times as great as in pure water.

In accordance with the theoretical shape of the solubility curves for tri-trivalent salts shown in the first paper of this series, all the curves for these salts are more like straight lines than those found with salts of lower types. That the individual nature of the solvent is here found to be much more pronounced than in the case of uni-univalent salts is likewise in agreement with the theory requiring changes in  $s/s_0$ , which for the same percentage change in the coefficient  $a$ , are greater in proportion to the absolute value of  $a$ .

### IX. General Remarks.

In the first paper of this series the expression

$$\log \frac{s}{s_0} = a (\sqrt[3]{c_1} - \sqrt[3]{s_0})$$

was chosen to cover approximately the solubility changes of salts in hetero-ionic solvents up to about 0.1 *N* solution,  $a$  being here a constant, which in uni-univalent salt systems has a value of about  $1/3$ . The experimental material in salt systems of the same type used in the present paper agrees approximately with the established equation, and an equation of the same structure seems to hold in the case of bivalent salt systems as well. However the individual behavior of the salt employed is more pronounced in the more developed material now at hand, and tends to obscure any numerical regularity in salt systems of promiscuous type. On the basis of the above experiments the following qualitative rules may be formulated. *The influence of the solvent increases with the increasing valence of the ion of the solvent salt, which in the case of the tri-bivalent salts leads to an enormous increase of solubility, even on the addition of solvents of very low concentration. When both the dissolved and dissolving ions are of the higher valence, the effect of the sign of the electric charge is very marked, producing the highest solubility values when the polyvalent ions of solvent and solute are of different sign.*

As already indicated in the first paper, the reason for the appearance of individuality in the solubility curves must be sought partly in the hydration of the solvent and the solute, and partly in the fact that in these ions we are dealing not with mass as points, but with particles of different sizes bearing a number of electric charges of opposite signs, the algebraic sum of which gives the net charge or valence of the ion.

It is probable that this influence of size of ion, especially in the field of metal ammonia salts considered in this paper, on account of the rather complicated molecular structure of these salts will in many cases prove to be of considerable magnitude.

Since the theory of solubility as here developed, showing the dependence of solubility on the solvent, is really nothing but a theory of solutions, the proper way of attacking the problem, when its complicated nature has been thus manifested, will be a more detailed systematic examination of single cases of equilibrium, rather than the broad consideration of an elaborate mass of material, such as is given in the present paper. The knowledge now available as to the general behavior of salts as saturating substances in salt solution is, however, of great value in such a closer study of single cases. The conclusive results achievable from experiments in this direction will be the subject matter of the next article in this series.

## THE CRYSTAL STRUCTURE OF AMMONIUM CHLOROPLATINATE.

BY RALPH W. G. WYCKOFF AND EUGEN POSNJAK.

Received June 24, 1921.

**Introduction.**—This study of the crystal structure of ammonium chloroplatinate is intended primarily to furnish an illustration of the application of that method of studying the structures of crystals which arises from the use of the theory of space groups.<sup>1</sup> At the same time it will show the possibilities and more especially the present limitations in the study of any but the very simplest of structures.

**Outline of the Determination.**—The study of the arrangement of the atoms in this crystal will be carried out through the following main steps: (1) a consideration of the X-ray reflection spectrum from some important crystal face, in order to determine the absolute dimensions of the unit cell and to indicate the number of chemical molecules to be associated with it; (2) a description, with the aid of the results of (1), the crystallographic data, and the theory of space groups, of all of the ways in which it is possible for the atoms of ammonium chloroplatinate to be arranged; (3) the obtaining of diffraction data suitable for distinguishing between these various possible structures and the determination of the correct one to represent the arrangement of the atoms within the crystals of this salt.

**The Specimens.**—The crystals that were employed for this investigation are clear octahedrons 2 to 3 mm. on their largest diameters. They were sufficiently small so that the Laue photographs, to be described later, were prepared by passing the X-rays through the entire crystal without

<sup>1</sup> P. Niggli, "Geometrische Krystallographie des Discontinuums," Leipzig, 1919; Ralph W. G. Wyckoff, *Am. J. Sci.*, 1, 127 (1921) and earlier papers.

first cutting a thin section. Owing to the fact that the crystals were smaller than the pin-hole beam of X-rays, the spots of these photographs were no longer elliptical but bore a shape that was conditioned by the shape of the crystal. The reflection spectra were obtained from faces that were not more than 2 mm. on a side. It is of interest to note that satisfactory data for the determination of the structure of a crystal at least in some instances can be obtained from such small crystals.

**The Reflection Spectrum and the Number of Chemical Molecules within the Unit Cell.**—A comparison X-ray spectrum from the cleavage (100) face of calcite and from the octahedral (111) face of ammonium chloroplatinate was prepared in the usual manner by mounting the two crystals one above the other upon the rotating table of an X-ray spectrometer. The radiation was taken from a tungsten tube. The drawing of Fig. 1 shows the spectra that were thus obtained.<sup>2</sup> Knowing

the wave lengths of the reflected X-rays and also the spacing of calcite against the (100) plane, it is possible from the measurement of its spectrum to eliminate errors in the spectrograph used by calculating in the following manner the distance from the crystal to the photographic plate.

TABLE I.  
THE CALCITE SPECTRUM FROM THE (100) FACE.  
 $d/n = 3.0281 \times 10^{-8}$  cm.<sup>4</sup>

Line.	Wave length $\times 10^{-8}$ cm.	Distance (a) (on plate). Cm.	$\sin \theta$ .	$\tan \theta$ .	Distance (b) (crystal-plate). Cm.
$\beta_2$	1.242	4.34	0.2048	0.4377	9.91 <sup>5</sup>
$\gamma_1$	1.095	3.78	0.1807	0.3804	9.93 <sup>7</sup>
$\gamma_2, \gamma_3$	1.061	3.64	0.1751	0.3674	9.90 <sup>7</sup>

9.91<sup>7</sup>

By rearrangement of the equation  $n\lambda = 2d \sin \theta$ ,<sup>3</sup> it is seen that  $\sin \theta = n\lambda/2d$ ; furthermore  $\tan 2\theta$  gives the ratio of (a) the distance of a spectrum line from the central image upon the photographic plate and (b) the dis-

<sup>2</sup> Partly because of the comparatively long time that was required to obtain a satisfactory spectrum, the resulting photograph was so blackened by scattered radiation that its reproduction would not have been satisfactory. The drawing of Fig. 1 is made from a tracing of this spectrum.

<sup>3</sup> In this equation as usual  $n$  = the order of the reflection,  $\lambda$  = the wave length of the reflected X-rays,  $d$  = the spacing between like reflecting planes, and  $\theta$  the angle of the reflection.

<sup>4</sup> W. Duane, Nat. Research Council, *Bull.*, 1, 383 (1920).

tance from the crystal to the photographic plate. This latter distance ( $b$ ) can thus be calculated for this particular spectrum from the spectrum of calcite (Table I, p. 2293).

Since  $d/n = \frac{1}{2\lambda} \sin \Theta$ , the reflection from the (111) face of ammonium chloroplatinate can be calculated in a similar manner (Table II).

TABLE II.  
THE AMMONIUM CHLOROPLATINATE SPECTRUM FROM THE (111) FACE.

Line.	Wave length $\times 10^{-8}$ cm.	Distance ( $a$ ) (on plate). Cm.	$\tan 2\Theta$ .	$\sin \Theta$ .	$(d/n)_m$ . Cm.
$\alpha_1$	1.473	2.63	0.2652	0.1293	$5.690 \times 10^{-8}$
$\beta_1$	1.278	2.28	0.2299	0.1127	5.668
$\beta_2$	1.242	2.20	0.2218	0.1089	5.696
$\gamma_1$	1.095	1.94	0.1956	0.0964	5.678

5.683  $\times 10^{-8}$

The number of chemical molecules associated with the unit cell of a cubic crystal, or rather, since the order of the observed reflection cannot be told with any degree of assurance, the ratio of the number of molecules to the cube of the order of the reflection,  $m/n^3$ , can be obtained from the following expression,

$$m/n^3 = \frac{(d/n)_{100}^3 \times \rho}{M}, \quad (1)$$

where  $M$ , the mass of a chemical molecule of the salt is equal to its molecular weight multiplied by the weight of an atom whose atomic weight is unity (roughly equal to the weight of a single atom of hydrogen =  $1.64 \times 10^{-24}$  g.), and  $\rho$  = the density of the crystal. The spacing of any plane ( $hkl$ ) is related to the spacing of the cube (100) plane of a cubic crystal by the following equation,

$$d_{hkl} = \frac{d_{100}}{\sqrt{h^2 + k^2 + l^2}}. \quad (2)$$

Substituting in Equation 1 the value of  $d_{100}$  obtained by transposing Equation 2, the value of  $m/n^3$  for a cubic crystal can be calculated from the measurement of the reflection spectrum from any crystal face through

$$m/n^3 = \frac{(d/n)_{hkl}^3 \times (h^2 + k^2 + l^2)^{3/2} \times \rho}{M}. \quad (3)$$

The values of the density of ammonium chloroplatinate which have been recorded are sufficiently discordant so that a redetermination seemed desirable. Using a pycnometer method<sup>5</sup> the density at 30° against water at 4° was found to be 3.065. The substitution of the appropriate values for ammonium chloroplatinate in Equation 3 gives for  $m/n^3$  the value of 4.021. If this value is considered in the light of a table giving values for

<sup>5</sup> J. Johnston and L. H. Adams, THIS JOURNAL, 34, 566 (1912).

$m/n^3$  for all possible values of  $m$  and  $n$ , it becomes evident that in this case either<sup>6</sup>  $m=4$  and  $n=1$ , or  $m=32$  and  $n=2$ .

If  $n=1$  then the application of Expression 2 to the spacing calculated for the (111) planes gives a length of the side of the unit cube of  $d_{110} = d_{111} \times \sqrt{3} = 9.843 \times 10^{-8}$  cm. If, however,  $n=2$ , this dimension is twice as great, namely,  $19.686 \times 10^{-8}$  cm.

**The Possible Arrangements for the Atoms in Ammonium Chloroplatinate.**—From a knowledge of all of the special cases of the space groups it is possible to write down all of the ways in which the atoms of ammonium chloroplatinate can be arranged within the unit cube, if the class of symmetry to which the crystal should be assigned is known.

Etch figures upon different faces of crystals of this salt have been studied,<sup>7</sup> so that from the standpoint of the crystallographer its *symmetry* is quite definitely established as that of the normal, or holohedral, class of the cubic system. Ammonium chloroplatinate must then be assigned to one of the 10 space groups,  $O_h^{1-10}$ , which possess this symmetry.

Two cases arise, one if it is assumed that  $m=4$  and  $n=1$ , the other if it is assumed that  $m=32$  and  $n=2$ . They will be discussed separately as follows.<sup>8</sup>

*I. Assuming that  $m=4$ ,  $n=1$ .* In Table III are stated the number and nature of the special cases of each of the 10 space groups  $O_h^{1-10}$ . The number outside of the parenthesis is the number of special cases having a particular number of equivalent positions (for like atoms) within the unit cell; the number in parenthesis is the number of variable parameters possessed by these arrangements.

Since ammonium chloroplatinate has the formula  $(NH_4)_2PtCl_6$  and since it is assumed here that 4 chemical molecules are to be contained within the unit cube, this cell must contain 4 platinum atoms, 8 nitrogen atoms, 24 chlorine atoms and 32 hydrogen atoms. An inspection of Table III shows that there are but two ways of arranging the 4 platinum atoms within the unit; (1) 3 of them must be alike and different from the fourth, both chemically and crystallographically; or (2) all 4 must be alike. If the 4 platinum atoms are not all alike (1), then the positions of the atoms within the unit cube must be those of special cases of the space group  $O_h^1$ ; otherwise (2) they must be assigned to either space group  $O_h^4$  or space group  $O_h^5$ . There is every reason to believe that the 4 platinum atoms are chemically, and hence also crystallographically, all alike (2). For the sake of completeness, however, both possibilities will be listed at this point. All of the special cases of these three space groups,  $O_h^1$ ,  $O_h^4$  and

If 3 of the platinum atoms are alike and different from the fourth platinum atom, then it would be anticipated from the chemical composition of the salt that 6 of the ammonium groups and 18 of the chlorine atoms would be alike but different in some manner from, respectively, the other 2 ammonium groups and the other 6 chlorine atoms (which would be alike among themselves). The space group  $O_h^1$  has no special case having 18 equivalent positions within the unit. Furthermore, suitable special cases do not exist for assuming, for instance, that all of the hydrogen atoms in an ammonium group are not alike or that some of the chlorine atoms about the platinum atoms are different from others, while still maintaining a "three group alike and one group different" arrangement to correspond with the platinum atoms. As a consequence any arrangement of the atoms of ammonium chloroplatinate based upon this space group  $O_h^1$  seems thoroughly improbable from the standpoint of its chemistry. Considered, however, solely as a geometrical problem there are ways of arranging the requisite number of atoms within the unit cell. They are as follows. Possible arrangement (a): *platinum* atoms, 1a or 1b, and 3a or 3b; *chlorine* atoms, 2 of the arrangements having 12 equivalent positions, or 3 sets of the 8 equivalent positions obtained by assigning 3 different values to u, or 4 sets of 6 equivalent positions obtained in a similar manner; *nitrogen* atoms, 8 equivalent positions obtained by assigning some value to u of 8c; *hydrogen* atoms, 4 sets of 8 equivalent positions obtained by assigning 4 different values to the u of 8c, or 2 sets of the 12 equivalent positions and one of the 8 equivalent positions, or 4 different sets of 6 equivalent positions and one of 8 equivalent positions, etc.

It has already been pointed out that if all 4 of the platinum atoms are alike the arrangement of the atoms must be that of either  $O_h^4$  or of  $O_h^5$ . There is every reason to believe that all 4 of the hydrogen atoms in the ammonium radical are chemically identical.<sup>9</sup> If this is correct then these hydrogen atoms by the very definition of their likeness have neighboring atoms arranged in the same way about each. Since in neither of these space groups are there more than 2 special cases having 4 equivalent positions within the unit and since one of these two special cases must be taken up by the platinum atoms, it follows that all 8 of the nitrogen atoms must be alike. Then if the 4 hydrogen atoms of the ammonium group are taken as alike, there must be 32 equivalent hydrogen atoms within the unit cell. This is possible only with the space group  $O_h^5$ . It may consequently be concluded, if the chemical nature of ammonium chloroplatinate is taken into account, that its symmetry is that of the space group  $O_h^5$ .

Two types of ways of arranging the atoms of ammonium chloroplatinate according to the special cases of this space group,  $O_h^5$ , exist. They are as follows. Possible arrangement (b): *platinum* atoms, 4b or 4c; *chlorine* atoms, 24a; *nitrogen* atoms, 8e; *hydrogen* atoms, 32a. Possible arrangement (c): *platinum* atoms, 4b or 4c; *chlorine* atoms, 24c; *nitrogen* atoms, 8e; *hydrogen* atoms, 32a.

In any grouping developed from  $O_h^5$ , a study of its special cases will show that all of the chlorine atoms must be alike and equally distant from a platinum atom. From the chemical nature of ammonium chloroplatinate, again, it is evident that the chlorine atoms are more tightly bound to the platinum atoms than to the ammonium radicals; and according to any reasonable law of force between atoms this would indicate that the chlorine atoms should be nearer to the platinum atoms than to the nitrogen atoms. In arrangement (c) the chlorine atoms lie closer to the nitrogen atoms than to the platinum atoms so that once more employing chemical evidence it can be stated with a considerable degree of probability that the arrangement of the atoms in ammonium chloroplatinate crystals *must* be that defined by arrangement (b).<sup>10</sup>

If this sort of chemical evidence is ignored there are a considerable

<sup>9</sup> For instance the fact that different but isomeric compounds obtained by substituting different organic radicals in place of the hydrogens of ammonium are not obtained seems to point conclusively in this direction.

<sup>10</sup> This discussion has not taken into account the idea of atomic spheres of influence of definite size (W. L. Bragg, *Phil. Mag.*, [6] 40, 169 (1920)). Upon this basis also the chlorine atoms should be nearer to the platinum than to the nitrogen atoms, if the radius of the platinum atom is taken from the recent determination of the structure of the metal (A. W. Hull, *Phys. Rev.*, 17, 571 (1921)) and if the dimensions of the ammonium group are obtained from measurements made on ammonium chloride (W. H. and W. L. Bragg, "X-rays and Crystal Structure," Bell and Sons, London, 1918, p. 111).

number of different ways in which the requisite number of atoms of platinum, nitrogen, chlorine and hydrogen can be grouped within unit cells, and with the existing lack of precise knowledge concerning the laws of scattering it would be a practically hopeless task to try to eliminate them absolutely upon the basis of their predicted diffraction effects. These other possible arrangements would be developed from the space group  $O_h^4$  and would be of the following type. Possible arrangement (d): *platinum* atoms, 4d or 4e; *chlorine* atoms, one set of 24 equivalent positions, or 2 sets of 12 equivalent positions, or 3 sets of 8 equivalent positions, or one set of 12, one of 8 and one of 4 equivalent positions, or arrangements developed by putting 6e and 2a in place of any of the above sets of 8 equivalent positions; *nitrogen* atoms, 8d; *hydrogen* atoms, one set of 24 and 8d, or one set of 24 equivalent positions, 6e and 2a, or 2 sets of 12 or 3 sets of 8 in place of one set of 24 equivalent positions in either of the above, or 4 sets of 8 equivalent positions.

II. Assuming that  $m = 32$ ,  $n = 2$ . If this is the correct amount of mass to be associated with the unit cube, each unit must contain 32 platinum atoms, 64 nitrogen atoms, 192 chlorine atoms and 256 hydrogen atoms. If all 4 of the hydrogen atoms in ammonium are alike it is impossible to associate 32 molecules with the unit cell (unless it be assumed that some of the platinum atoms are different from others) because the maximum number of equivalent positions within the unit cell of any space group is 192. If, however, it is allowed that some of the hydrogen atoms in ammonium may be different from others, then a considerable number of geometrically possible, though chemically far from understandable, groupings can be developed. A consideration of Table IV shows that 3 space groups,  $O_h^5$ ,  $O_h^7$  and  $O_h^8$ , possess special cases with 32 equivalent positions within the unit cube. Two of these, the first two, also show as many as 192 equivalent positions within the unit cell. From either of these if all chemical evidence is disregarded, and in fact from  $O_h^8$  also, it would be possible to build up very complicated arrangements for the atoms of ammonium chloroplatinate. To eliminate with certainty these groupings by a comparison of the diffraction effects which they would produce with those found by experiment is practically impossible in the present state of our knowledge. Since, in the light of chemical evidence, they are at least highly improbable, they will be omitted from further consideration.

**Distinguishing between the Possible Arrangements.**—By making the single assumption that all of the 4 hydrogen atoms of the ammonium radical are chemically exactly alike, it has been shown that the atoms of ammonium chloroplatinate must be placed either according to arrangement (b) or arrangement (c). Of these two, one of them, (c), can be ruled out upon similar grounds. It is, however, possible to distinguish between these two arrangements from the difference in the diffraction effects which

they will produce, so that it is perhaps worth while, if only for purposes of illustration, to show by this instance the method of picking out diffraction effects which will be characteristic of different crystallographically possible arrangements and thus by investigating these characteristic effects to choose the correct grouping.

Calculations of terms proportional to the intensity of reflection from any plane ( $hkl$ ) in any order,  $n$ , of the spectrum have been made by means of an expression of the form

$$I \propto f(d/n) \sum_r [\sigma_r \cos 2\pi n(hx_r + ky_r + lz_r)]^2 + \sum_r [\sigma_r \sin 2\pi n(hx_r + ky_r + lz_r)]^2 \quad (4)$$

where  $I$  is the intensity of reflection,  $f(d/n)$  is a function of the spacing between like planes whose form is not known with great certainty (for the present it does not enter into this discussion), and  $\sigma_r$ , the scattering power of the atom  $r$  for X-rays, seems to be roughly proportional to the atomic number. The summation is to be taken to cover each of the atoms within the unit cube. For convenience in writing  $A$  will be written for the summation of the cosine terms (not squared) and  $B$  for the summation of the corresponding sine terms. This expression (4) would be written  $I \propto f(d/n)[A^2 + B^2]$ .

Applied to the different kinds of atoms of arrangements (b) and (c) this expression gives terms for the intensity of reflection from any plane as follows.

#### Platinum atoms

4b. When  $n=1$ : if  $h=2m$ ,  $k=2p+1$ ,  $l=2q+1$ , where  $m$ ,  $p$  and  $q$  are any integers (indices=one even, two odd), then  $A=0$ ; the similar sine term,  $B=0$ , also; if  $h=2m$ ,  $k=2p$ ,  $l=2q+1$  (two even, one odd indices), then,  $A=0$ ,  $B=0$ ; if  $h=2m+1$ ,  $k=2p+1$ ,  $l=2q+1$  (all odd indices), then,  $A=4Pt$ ;  $B=0$ . 4c. When  $n=1$ : if  $h=2m$ ,  $k=2p+1$ ,  $l=2q+1$ , then  $A=0$ ,  $B=0$ ; if  $h=2m$ ,  $k=2p$ ,  $l=2q+1$ , then  $A=0$ ,  $B=0$ ; if  $h=2m+1$ ,  $k=2p+1$ ,  $l=2q+1$ , then  $A=-4Pt$ ,  $B=0$ .

#### Nitrogen atoms

8e. When  $n=1$ : if  $h=2m$ ,  $k=2p+1$ ,  $l=2q+1$ , then  $A=0$ ,  $B=0$ ; if  $h=2m$ ,  $k=2p$ ,  $l=2q+1$ , then  $A=0$ ,  $B=0$ ; if  $h=2m+1$ ,  $k=2p+1$ ,  $l=2q+1$ , then  $A=0$ ,  $B=0$ .

#### Chlorine atoms

24c. When  $n=1$ : if  $h=2m$ ,  $k=2p+1$ ,  $l=2q+1$ , then  $A=0$ ,  $B=0$ ; if  $h=2m$ ,  $k=2p$ ,  $l=2q+1$ , then  $A=0$ ,  $B=0$ ; if  $h=2m+1$ ,  $k=2p+1$ ,  $l=2q+1$ , then  $A=0$ ,  $B=0$ .

24a. When  $n=1$ : if  $h=2m$ ,  $k=2p+1$ ,  $l=2q+1$ , then  $A=0$ ,  $B=0$ ; if  $h=2m$ ,  $k=2p$ ,  $l=2q+1$ , then  $A=0$ ,  $B=0$ ; if  $h=2m+1$ ,  $k=2p+1$ ,  $l=2q+1$ , then  $A=Cl[8 \cos 2\pi u(2m+1) + 8 \cos 2\pi u(2p+1) + 8 \cos 2\pi u(2q+1)]$ ,  $B=0$ .

*Hydrogen atoms*

The term for the hydrogen atoms will not be taken into consideration for, since the scattering power of an atom of hydrogen is so slight, the effect even of 3 such atoms can scarcely be qualitatively observed.

The value of (4) for arrangements (b) and (c) can be written directly by combining the terms for each of the atomic positions. When  $n=1$  they thus become (neglecting the hydrogen terms).

Arrangement (b): when the indices are either 2 even and 1 odd or 2 odd and 1 even,  $A=0$ ,  $B=0$ ; when the indices are all odd,  $A=\pm 4Pt+8Cl[\cos 2\pi hu + \cos 2\pi ku + \cos 2\pi lu]$ ,  $B=0$ ;.....(5)

Arrangement (c): except when the indices are all odd  $A=0$ ,  $B=0$ ; then  $A=\pm 4Pt$ ,  $B=0$ . ....(6)

When  $n=2$ : all terms will have appreciable values in the second order so that in dealing with such qualitative measures of diffraction as are now available, discussion will be limited to the first-order region.

Fig. 2.—A print of the Laue photograph obtained by passing the X-rays in a direction roughly normal to the (111) face of ammonium chloroplatinate.

It is evident that for either (b) or (c) only planes all of whose indices are odd will give first order reflections. Both are in agreement with the results of the reflection spectrum photograph. The most satisfactory way of assuring the correctness of one or the other of these two possibil-

ities and of deciding between them lies then in considering the reflections in the first order from a large number of planes. This is most satisfactorily done at the present time by the study of Laue photographs. This same study should give as well an indication of the position of the chlorine atoms. Their location cannot now be expected with great accuracy without an excessive amount of labor because (1) the hydrogen atoms, though present in a considerable number and hence of quantitative importance, are as already suggested qualitatively insignificant, and (2) because the scattering power of platinum is so great compared with that of chlorine that small changes in the position of the chlorine atoms would be likewise qualitatively of small account. As soon as these reflections can be satisfactorily treated in a quantitative fashion this placing of the chlorine atoms should be easily made.

Two Laue photographs were studied in detail by the customary methods. One, taken normal to the (111) plane, showed reflections from about 400

Fig. 3.—A print of the Laue photograph obtained by passing the X-rays in a direction roughly normal to the (100) face of ammonium chloroplatinate.

planes (Fig. 2); the other, tilted somewhat from a normal to the cube plane, contained about 200 spots (Fig. 3). The gnomonic projections of these two photographs are shown in Figs. 4 and 5. By enlarging by the amount shown in the first two figures, these projections will duplicate

the conditions of the original experiment so that from them can be obtained all of the data now available from these photographs. A rough measure of the intensities of the spots is given by the size of the spots in the central reproduction of the photograph, the most intense spots being made the largest. The reproductions of the original photographs (Figs. 2 and 3) are added to make possible slightly more accurate estimations of the intensities of the brighter spots (the only ones that show). A spot can be identified with the projection of its plane in the usual manner, most conveniently by using some such ruler as that already described; and its distance from the central spot and the indices of its reflecting plane can be

Fig. 4.—The gnomonic projection of the Laue photograph of Fig. 2. Reduced.

directly obtained from measurement upon the central reproduction and upon the projection respectively.<sup>11</sup> The angle  $\theta$  of the reflection can be calculated for any spot from a knowledge of the distance from the crystal to the

<sup>11</sup> It would not be feasible to record the measurements upon approximately 600 planes together with the calculations of the wave lengths producing the spots and their estimated intensities. The inclusion of this mass of data would give an utterly false impression of their present value. Rather than leave out all results, however, the condensed description outlined in the text has been used. In spite of its obvious disadvantages it is possible with such reproductions as are shown here to record in a short space all of these data in such a form that those sufficiently interested can work them out with an approximation to the original accuracy.

photographic plate (which in both of these cases was 5 cm.) and from a measurement of the distance of the spot from the undiffracted image. Combined with a knowledge of the indices of the reflecting plane and by using Expression 2 and the equation  $n\lambda = 2d \sin \theta$ , this evaluation of  $\theta$  makes possible the determination of  $n\lambda$  for each spot.

In neither of these photographs were any spots observed in the first order region (assuming that the number of molecules to be associated with the unit cell is 4 and hence that the reflection observed from the (111) face in the spectrum photograph was of the first order) except those all of whose indices are odd numbers. Some of the indices of these first order

Fig. 5.—The gnomonic projection of the Laue photograph of Fig. 3. Reduced.

planes are such complicated ones as  $(\bar{9} \ 11 \ 5)$  or  $(5 \ \bar{13} \ 3)$  so that the complete absence of any but all-odd planes leaves no doubt as to the truth of the general statement that only planes having all odd indices are found in the first order region. This observation is very strong evidence for the correctness of either arrangement (b) or arrangement (c).

The terms proportional to the amplitude (square root of the intensity) of the first order reflections from arrangements (b) and (c) have been shown to be arrangement (c),  $A = 4Pt$ ; arrangement (b), with the platinum atoms at 4b,  $A_{4b} = 4Pt + 8Cl[\cos 2\pi hu + \cos 2\pi ku + \cos 2\pi lu]$ ; with the platinum atoms at 4c,  $A_{4c} = -Pt + 8Cl[\cos 2\pi hu + \cos 2\pi ku + \cos 2\pi lu]$ . But  $A_{4c} =$

$-A_{4b}$  if  $u_{4c}=u_{4b} + \frac{1}{2}$  so that it will be sufficient to discuss but one case (the one involving  $4b$  will be chosen).

It is customary to assume that  $f(d_{hkl}/n)$  in Equation 4 has the form of  $(d_{hkl}/n)^2$ . If this is true and if the atoms are arranged according to (c) then the intensity of the first order reflections from the different planes ( $hkl$ ), at the same wave lengths, should stand in the order of the value of  $1/(h^2 + k^2 + l^2)$ . If, on the other hand, the chlorine atoms have the arrangement (b), this order of intensities will be inverted in part by reason of the term which these chlorine atoms contribute towards the amplitude. Such irregularities are found in the results from the Laue photographs and this may be taken to show that the correct arrangement is that of (b).<sup>12</sup>

A more detailed discussion of such reflections should give an indication of the value of  $u$  for the chlorine atoms. From the results of the study of the Laue photographs, for instance, the following comparisons of the intensity of reflection of waves of practically the same length from different planes are possible

$$\begin{aligned}(173) &< (171) \text{ (by a small amount),} \\ (171) &< (191), \\ (751) &< (171), \\ (751) &< (191) \text{ (by a considerable amount).}\end{aligned}$$

The positions of the chlorine atoms are defined by  $u$  which must consequently be assigned such a value that the above experimental facts must be accounted for when the value of  $(h^2 + k^2 + l^2)$  is taken into consideration (a qualitative ordering of the intensity of the reflections on the basis of this  $f(d/n)$  factor is sufficient). This  $u$  is most readily found by plotting it for each of these planes (Fig. 6) against the corresponding amplitude of reflection as determined through the intensity Equation 5. It is obvious from the form of arrangement 24a that the function will be symmetrical about  $u=0.5$  so that it is sufficient to consider  $u$  from  $u=0$  to  $u=0.5$ . The data given here allow two possible positions for the chlorine atoms, one about  $u=0.1$ , the other close to  $u=0.225$  (Fig. 6). The first of these seems improbable because it would bring the centers of the chlorine and platinum atoms nearer together than is to be anticipated; no data were found, however, definitely to rule out this possibility. If the second position is the correct one the value for  $u$  must lie between  $u=0.22$  and  $u=0.24$ .

It is of interest to calculate, using the idea of closely packed atomic spheres,<sup>13</sup> the expected distance of the chlorine from the platinum atoms

<sup>12</sup> Variations from the normal decline of intensity with increasing values of  $(h^2 + k^2 + l^2)$ , though of but slight amount, would be produced in (c) by the hydrogen atoms. The observed effects seem to be much greater, however, than would be expected from the introduction of this factor into the intensity equation for (c).

<sup>13</sup> W. L. Bragg, *Phil. Mag.*, [6] 40, 169 (1920).

and to compare this distance with the results of the above determination. The radius of the platinum atom, as calculated from the structure of platinum metal<sup>14</sup> is  $1.39 \times 10^{-8}$  cm. To chlorine has been assigned the radius  $1.05 \times 10^{-8}$  cm.<sup>13</sup> Upon this basis then the distance from chlorine to platinum should be  $2.44 \times 10^{-8}$  cm. Taking  $u=0.23$  and knowing the length of the unit cube to be  $9.843 \times 10^{-8}$  cm., this distance is  $2.26 \times 10^{-8}$  cm. (If  $u=0.24$ , it is  $2.36 \times 10^{-8}$  cm.)

Fig. 6.—Curve 1 = planes of the form (571); Curve 2 = (173); Curve 3 = (171); Curve 4 = (191).

As soon as careful measurements of intensity become possible and satisfactory knowledge of the nature of scattering is available, the more accurate placing of the chlorine atoms in ammonium chloroplatinate and a comparison between their positions in this compound and in other chloroplatinates, as well as a comparison of the structures of these crystals with the analogous fluosilicates, chlorostannates, bromoplatinates, etc., will be easily accomplished and will be of considerable interest.

**Conclusion.**—Making use of the single assumption, which seems to be itself entirely justified, that the 4 hydrogen atoms in the ammonium group are all chemically alike, it has been shown that the atoms in the unit cube of ammonium chloroplatinate have the following coordinate positions: *platinum* atoms, 4b; *chlorine* atoms, 24a, the value of  $u$  probably lying between  $u=0.22$  and  $u=0.24$ ; *nitrogen* atoms, 8c; *hydrogen* atoms, 32a, the value of  $u_H$  being unknown. The length of the side of this unit cube is  $9.843 \times 10^{-8}$  cm. The arrangement of its atoms is shown in Fig.

<sup>14</sup> A. W. Hull, *Phys. Rev.*, **17**, 571 (1921).

7: Fig. 7a shows the positions of only the platinum and nitrogen atoms within a unit cell; Fig. 7b gives the arrangement of all of the atoms within a small cube which has one-eighth of the volume (and one-half the length of side) of this unit.

Fig. 7a.

Fig. 7b.

The arrangement of the atoms within the unit cell of ammonium chloroplatinate. Fig. 7a shows the positions of the platinum and nitrogen atoms within the unit; Fig. 7b gives the positions of all of the atoms within the small cube that has one-eighth of the volume of the unit.

**The Chemical Significance of this Crystal Structure.**—This crystal structure of ammonium chloroplatinate is most easily described by saying that it is the same as that of fluorspar ( $\text{CaF}_2$ ) if for the bivalent positive calcium atoms bivalent negative  $\text{PtCl}_6$  groups are substituted and if the monovalent fluorine atoms are replaced by monovalent ammonium radicals. There can be no doubt but that  $\text{PtCl}_6$  groups of atoms function in solution as doubly (negatively) charged ions and that the ammonium radicals under the same conditions are singly charged (positively). Since their crystallization is a strictly analogous process to the crystallization of such salts as the alkali halides, for which there is considerable evidence that the atoms remain ions (that is, remain electrically charged) in the solid state, it is natural to assume that very probably there exists within the crystal of ammonium chloroplatinate the ions of  $\text{PtCl}_6$  and of  $\text{NH}_4$ . The fact that the corresponding compound calcium fluoride  $\text{CaF}_2$ , which from the chemical nature of its elements is presumably also an "ion" compound, has an analogous structure, would seem to indicate that this arrangement is the most stable, or at least is an exceedingly stable, way of grouping one doubly charged and two singly charged (of opposite sign to the doubly charged) atoms or groups of atoms in the crystalline state.

### Summary.

Crystals of ammonium chloroplatinate  $((\text{NH}_4)_2\text{PtCl}_6)$  probably have a structure which is analogous to that commonly assumed for fluor spar, if  $\text{PtCl}_6$  groups replace the calcium atoms and if  $\text{NH}_4$  groups are introduced in place of the fluorine atoms. This determination was made by and serves as an illustration of the general method (previously discussed) for the study of the structure of crystals which is based upon the theory of space groups.

The only assumption made that is not required in the ordinary determination of the wave length of X-rays from a reflection spectrum was that the 4 hydrogen atoms of the ammonium radical are exactly alike; with this exception, that in attempting to place the chlorine atoms with accuracy, it was assumed that atoms scatter X-rays in an amount which is roughly proportional to their atomic numbers and that in a lattice arrangement of atoms the intensities of reflection follow qualitatively the order of  $1/(h^2 + k^2 + l^2)$ .

### A DIFFERENTIAL THERMOMETER.

BY ALAN W. C. MENZIES.

Received July 2, 1921.

One type of differential thermometer measures the difference of temperature existing at the same location at different times; a second type measures the difference in temperature existing simultaneously at different points in space. The thermometer here described is of the latter type.

A well-known differential thermoscope of this type consists of two glass bulbs containing air, otherwise closed but communicating with each other through a U-tube partly filled with oil, whose change of level indicates change of temperature by responding to change of gas pressure within the bulbs. When this instrument is developed into a differential thermometer, certain disadvantages become apparent, of which three will here be mentioned. (1) When the manometric liquid is caused to run into one of the bulbs by accidental tilting, perhaps during transportation, then it is difficult to return the liquid into precisely the same position as it occupied when the instrument was scaled. If stopcocks are introduced in the effort to avoid this inconvenience, the cure may become worse than the disease i. e. use of zero-creep. (2) In the presence of permanent gas, the manometric liquid becomes, in practice, not infrequently broken into threads, separated by short columns of the gas. This inconvenience, albeit only temporary, is nevertheless annoying. (3) Although oils furnish very sensitive manometric liquids, their use, or, indeed, the use of any liquid

other than the insensitive mercury, allows the entrance of an error that has been too little appreciated. The incidence of this error in tensimetric work has been pointed out by the writer in another connection.<sup>1</sup> The error in question is caused by the fact that a gas at higher pressure has a larger weight solubility than the same gas at a lower pressure. The permanent gas, always slightly soluble in manometric liquids other than mercury, therefore passes by a process of solution and diffusion from the side of higher to that of lower pressure. For this reason, even stopcock-free instruments of the kind referred to suffer from slow creep of the zero point.

In order to avoid these and other disadvantages, all that is necessary is to abandon entirely the use of permanent gas. One selects as manometric

Fig. 1

fluid not oil but some liquid whose change of vapor pressure per degree in the range of temperature where the differential measurements are to be made is such as to cause differences of pressure in the two bulbs of the thermometer that will register themselves by adequate differences of level of the fluid itself. The diagram, Fig. 1, shows one simple form useful in ebullioscopy, made from glass tubing a few millimeters in bore and having, without its handle, a length of perhaps 12 cm. Permanent gas is removed prior to sealing by the process of boiling out familiar to many who have had occasion to measure vapor pressures. For reading the difference of level of the two liquid surfaces a millimeter scale may be etched on both limbs.

From what has been said, it will be clear that, if the environment of both limbs of the instrument is the same in temperature, then the difference of level of the ends of the column of filling liquid will be merely that due to capillarity. If, however, the temperature of the lower bulb in Fig. 1, for example, be higher than that of the other limb, the consequent difference of pressure of vapor in the two limbs will cause in the liquid a correlative change of level whose value may be used, with the help of a suitable table, as a measure of the difference of temperature that caused it.

It is obvious that the sensitiveness in any particular range of temperature may be given widely different values according to the rate of change of vapor pressure of the liquid selected. The difference of temperature between upper and lower bulbs that will cause a change of level of, say, 1 mm. in the height of the column of the filling liquid may be computed from the known vapor pressures and densities of this liquid, and the results tabulated against the mean temperature of the instrument. Because of its suitability in other applications, and particularly because water is a filling liquid well adapted for use in these thermometers as employed in ordinary ebullioscopy, to be described in the article following, a table of precisely

<sup>1</sup> Menzies, *THIS JOURNAL*, 42, 1951 (1920).

the kind indicated is here furnished for a water-filled thermometer. The values for difference of pressure with temperature were obtained from the recent equation of Marvin,<sup>2</sup> which incorporates the best modern values, partly by direct differentiation and partly by the methods of interpolation. Against each tenth of a degree from 33° to 101.9° is tabulated the fraction of a degree centigrade that corresponds to an observed change of level of 1 mm. of water at this temperature. It may be noted that it is unnecessary at each observation to read the levels in both limbs, for the levels in the lower bulb that correspond to readings on the stem may be determined once for all, and the relationship graphed. The fact that such a graph should move parallel to itself as the total volume of contained water increases with temperature is immaterial when differential readings only are required, all close to the same temperature.

TABLE I.

Against each tenth of a degree from 33.0° to 101.9° is entered the change of temperature in ° C that would correspond to a vapor pressure change of water of 1 mm. head of water at the same temperature.

Although the thermometers are of different general types, as indicated above, it is of interest to compare this differential thermometer with the Cavendish-Walferdin<sup>3</sup> metastatic type as elaborated by Beckmann,<sup>4</sup> and as applied in the same field, for example that of ebullioscopy. With regard to length of scale per degree, the Beckmann mercurial type is

<sup>3</sup> Cavendish, *Trans. Roy. Soc. London*, 50, 300 (1757). Walferdin, *Bull. soc. géol. France*, 13, 113 (1841-2).

<sup>4</sup> Beckmann, *Z. physik. Chem.*, 2, 644 (1888); 51, 329 (1905).

limited by the usable size of bulb, and by the permissible narrowness of the capillary, so that a centigrade degree corresponds customarily to 40 or 50 mm. movement of the mercurial thread. The type here described is not thus limited in this respect, for a very low-boiling liquid may be used for filling. In both types the length of degree varies with the actual temperature. As to range, the Beckmann type is restricted to that between  $-39^{\circ}$  and  $+250^{\circ}$ .<sup>5</sup> While this is a much larger range than can be conveniently covered by the use of a single chosen liquid in the newer type, the simplicity of construction makes possible such a wide choice of filling liquids that a much wider range is easily available in the direction of lower as well as of higher temperatures. In comparing precision, one has to bear in mind, for the Beckmann type, possibilities of error due to (1) lack of uniformity of bore, (2) hysteresis in change of volume of bulb, (3) effect of pressure on volume of bulb, (4) sticking of mercury in capillary, (5) exposed thread, (6) difference of radiation to and from bulb, (7) departure of apparent degree from true degree. For the type here described, no one of the first six of these sources of error is important, for reasons that will be sufficiently obvious. In regard to (6), it may perhaps be said that error due to the change with environment of radiation loss suffered by a Beckmann thermometer at temperatures far from room temperature is here largely eliminated because suffered alike by upper and lower bulb. With regard to (7), it is indeed most necessary to employ a factor, different for each temperature, to convert observed readings to temperature; and this factor may be criticized as inconvenient to use, inaccurate in value and laborious of computation. But the use of a similar factor is likewise necessary, although frequently neglected, in the case of the Beckmann thermometer, whose degree, if true at  $0^{\circ}$ , is, for example, about 3% in error at  $80^{\circ}$ .<sup>6</sup> The accuracy of the conversion factor for the newer type is dependent in part on the accuracy with which the vapor pressure of the filling liquid is known. For such liquids as would be employed, and within the ranges of temperature that come in question here, this quantity, the vapor pressure, can now be measured to better than one part in 1000.<sup>7</sup> The process of computing factors for, perhaps, each tenth part of a degree over a considerable range of temperature may indeed be laborious; but, once published, the factor table may be used by every one. This inconvenience, therefore, is shifted from the shoulders of the user of the thermometer to those of him who first computed the table.

The Beckmann type is considerably more cumbersome as well as very much more fragile than the type here described, which one constructs from stout

<sup>5</sup> Cf. Staehler, "Arbeitsmethoden in der Anorg. Chemie," Veit and Co., Leipzig, 1913, part 3, vol. 1, i, p. 106.

<sup>6</sup> Staehler, *op. cit.*, p. 108.

<sup>7</sup> Cf. *THIS JOURNAL*, 32, 1412 (1910).

walled Pyrex tubing. In connection with fragility, it may be added that no "setting" of the thermometer for different temperatures is required, for its zero reading for uniform temperature automatically adjusts itself near the bottom of the stem, thus leaving the major portion of the scale available throughout its whole length.

In certain respects, therefore, it would appear that this type of differential thermometer has advantages over the Walferdin metastatic type as elaborated by Beckmann; and the question arises as to whether such other factors as are peculiar to a given application are favorable to its use. In studying its application in ebullioscopy, for example, as outlined in the article following, one finds that the important disturbing factor, peculiar to ebullioscopy in its incidence, of barometric fluctuation does not measurably affect the readings of the newer type, while such pressure fluctuations are among the chief outstanding sources of error when the metastatic type is used. Another application in a different field may be described in the near future.

#### Summary.

A very simple form of differential thermometer has been described whose indications depend on the registration by a column of manometric liquid in a U-tube of differences of vapor pressure of this liquid in opposite limbs. A table is given for use when the filling liquid is water; and mention is made of certain advantages of this type over the metastatic type of thermometer.

### THE APPLICATION OF A DIFFERENTIAL THERMOMETER IN EBULLIOSCOPY.

By ALAN W. C. MENZIES AND SYDNEY L. WRIGHT, JR.

Received July 2, 1921.

For purposes of molecular weight determination of dissolved substances, the ebullioscopic procedure has certain advantages over the method of cryoscopy. Since, to use the latter, one must for convenience employ solvents whose freezing points lie at easily accessible temperatures, it comes about that water, benzene and acetic acid have been commonly preferred. To obtain satisfactory values for the molecular weight of a solute, it is best to choose a solvent so like it chemically that compound formation shall be at a minimum. To be so closely restricted in the choice of solvents is therefore a disadvantage. Boiling temperatures are, in general, preferable to freezing temperatures as unfavorable to the formation of exothermic compounds. A majority of organic compounds boil normally below 300°. If, as is true, the solvent should differ by at least 150 degrees in boiling point from the solute in order that the volatility of the latter may

not vitiate the results, then, for most practical purposes, the use is indicated of such solvents as boil rather below  $100^{\circ}$  than above it, and these solvents are in point of fact those most commonly used. The low solubility of certain solutes at the freezing points of the available solvents is a factor against cryoscopy. On the other hand, the precision attainable in cryoscopy has, in the past, been considerably greater than that realized in ebullioscopy, even with apparatus fortified against error by the superimposition of a multiplicity of paraphernalia.

For these and other reasons, a very great deal of work has been carried out by very many investigators with a view to improving the ebullioscopic technique. One may but mention the two dozen papers by Beckmann and his collaborators;<sup>1</sup> and the work of Hite,<sup>2</sup> Orndorff and Cameron,<sup>3</sup> Jones,<sup>4</sup> Ross Innes,<sup>5</sup> Meyer and Desamari,<sup>6</sup> Drucker,<sup>7</sup> Sakurai,<sup>8</sup> Landsberger,<sup>9</sup> Walker and Lumsden,<sup>10</sup> McCoy,<sup>11</sup> Smits,<sup>12</sup> Rijber,<sup>13</sup> Ludlam,<sup>14</sup> Erdmann and Unruh,<sup>15</sup> Lehner,<sup>16</sup> and Turner.<sup>17</sup> Even a single publication by one writer, Hite, reports the trial of over 100 different forms of apparatus. In all these, and many other investigations, the bulb of a mercurial thermometer has been submerged beneath the surface of the boiling solution, and much of the work has been directed to the avoidance of the consequent irregular superheating. In our opinion, the two most successful improvements made since 1892 have originated in this country, the introduction, namely, by Bigelow<sup>18</sup> of electric heating, and by Cottrell<sup>19</sup> of a "lift-pump" which pumps the solution over the bulb of the thermometer, which no

longer need be submerged in the solution, but is located above the solution in the vapor phase. When Cottrell's device is employed, there remain outstanding, for non-volatile solutes, the errors inherent in the use of the Beckmann type of thermometer, the error due to uncertainty as to actual concentration of solute, and the very troublesome error due to change of boiling point caused by change of barometric pressure during the observations.<sup>20</sup> This last may, in part at least, be overcome by the employment of somewhat cumbersome "manostats,"<sup>21</sup> by especially constructed aneroid barometers,<sup>22</sup> or by the use of a second, duplicate, apparatus<sup>23</sup> operated simultaneously and containing another Beckmann thermometer immersed in the pure boiling solvent.

In 1910, Menzies<sup>24</sup> had described a simple apparatus, independent of barometric change, which, when properly constructed, gives molecular weights of solutes in solvents at their boiling points by direct measurement of lowering of vapor pressure, without the use of any thermometer. Continuing this effort at simplification, he found that the differential thermometer of the preceding article,<sup>25</sup> when applied to ebullioscopy with the Beckmann type of apparatus, served only to render more glaring the inevitable irregularities inseparable from that method of procedure. When however, Cottrell's paper appeared in 1919, opportunity was taken to work out the simplest possible apparatus and technique which should free ebullioscopy from all its most serious drawbacks.

**The Apparatus.**—The diagram, Fig. 1, shows a boiling tube, whose narrowed upper portion itself serves as condenser tube. A glass cylinder, open above and below and of diameter slightly less than the boiling tube, is located concentrically within the latter, and confers the advantages of a double jacket. Within this is supported the differential thermometer, on the lower bulb of which hangs the pump, loosely, as a hat on a peg.<sup>26</sup> The absence of rigid connection diminishes possibility of breakage, besides adding flexibility, literal and metaphorical.<sup>27</sup> The boiling tube is heated

<sup>20</sup> Cf. Meyer and Desamari, *Ber.*, 42, 2809 (1909), who were misled by this error into obtaining only one-half the true value for the molecular weight of tribromo-resoquinone, and so to assigning to it an inaccurate formula. The practical text-books often recommend postponing ebullioscopy to a day when the barometer is steady.

<sup>25</sup> Menzies, *ibid.*, 43, 2309 (1921).

<sup>26</sup> The complete apparatus, with both boiling tube and water-filled thermometer of Pyrex glass, is furnished by Messrs Eimer and Amend, 205 Third Avenue, New York, N. Y.

<sup>27</sup> We have on no occasion yet broken any part of the apparatus.

by direct contact with the low flame of a common Bunsen burner, protected by the customary draughtshield of metal, best in an inverted position. When boiling begins, portions of the liquid in the bulb are carried by the vapor in fragments up the pump and discharged to form a thin film over the lower bulb of the thermometer, which thus attains the temperature at which this liquid, or solution, is in equilibrium with the vapor. The upper bulb acquires the temperature of the pure boiling solvent. The thermometer registers the difference between these two temperatures. Equilibrium is reached so rapidly, except in cases of slow solubility, that fresh additions of solute may be made as fast as they can be weighed out. Contrary to all ebullioscopic tradition, the apparatus will give good results in a room that is not free from draughts. Unlike every other ebullioscopic apparatus, this form is entirely free from all corks, ground glass joints or stoppers.

The sources of error, including that due to barometric change, eliminated by the use of the new type of differential thermometer have been briefly referred to in the preceding article. The advantages gained by removing the lower bulb from immersion in the boiling liquid have been well explained by Cottrell,<sup>19</sup> and confirmed by Washburn and Read<sup>23</sup> and by Spencer,<sup>28</sup> to whose interesting papers the reader is referred for consideration of many matters that cannot be dealt with here. To their remarks may, perhaps, be added that the error due to change of bubble size caused by the marked change of surface tension on addition of certain solutes; that due to change of head of liquid above the thermometer bulb; and the errors caused by fractionation of the solvent and by slow removal by distillation of somewhat volatile solutes, incident to the Sakurai-Landsberger method, are also alike avoided. The chief residual source of error lies in the uncertainty as to the true concentration of the boiling solution as deduced, not by subsequent analysis, but simply from the weights of solvent and solute used. Part of the solvent is absent from the solution in the form of condensate on the walls, and part is absent in the form of vapor. This source of error, ever present in the Beckmann type of apparatus, has often failed of due consideration. To minimize it, we constrict the boiling tube above the lower bulb, mark cc. graduations on the cylindrical neck so developed, and read off the actual working volume of the solvent an instant after ebullition has been caused to cease, while the tube is still wet with condensate and filled with vapor.

Fig. 1.

<sup>28</sup> Spencer, *THIS JOURNAL*, 43, 301 (1921).

A simple water-filled differential thermometer suffices for the range of temperature from the boiling point of water to that of ether, thus embracing the use of such solvents as carbon disulfide, acetone, chloroform, methyl, ethyl and propyl alcohols, methyl acetate and iodide, ethyl formate, acetate, bromide and iodide; carbon tetrachloride, and benzene, and allowing a choice adequate for ordinary purposes. No "setting" of the thermometer is required for the use of different liquids.

**Method of Procedure.**—The boiling tube is clamped in a vertical position by means of a large single clamp located just under the upper side-tube of the condenser jacket. Beneath it is clamped a Bunsen burner at such a height that when the top of its tube is in position about 1 cm. below the bottom of the boiling tube, the base of the burner is a few centimeters above the sole of the supporting ring-stand. The boiling tube is filled with solvent to the level of the lower graduations on the constricted neck, the condenser water turned on, and the flame lighted and suitably adjusted by means of the customary screw-clip. The boiling point of the solvent is now taken to the nearest tenth of a degree by means of a good ordinary thermometer, in which operation the avoidance of exposed thread is usually easy. While the thermometer used for this purpose is reaching thermal equilibrium, the barometer may conveniently be read, and information thus obtained as to the purity of the solvent. The actual working volume of the solvent is next found by lowering the burner (not its gas supply) so that it is ready to be swung clear, quickly swinging it aside, and causing instant cessation of bubble formation by immersing the bottom of the boiling tube in cold water raised by hand from below in a small beaker. The reading of volume—best against a white card in the background—should be made immediately ebullition is caused to cease, before the access of solvent that drains from the walls. The burner is then replaced in position. For purposes of molecular-weight determination, one may employ as ebullioscopic constant the boiling-point rise in degree produced by one mole of solute per 100 cc. of solvent at its boiling point ( $K_2$  in Table I p. 2320). The mercurial thermometer is now withdrawn, the pump introduced and lowered to the bottom of the boiling tube by means of a deep hook on the end of a wire, and the differential thermometer inserted, engaged on the pump, and clamped in suitable position by the end of its handle which is made wide so as to be more easily gripped by the clamp. While temperature equilibrium is being reached, which may occupy 15 minutes, it is convenient to prepare pastilles of the solute and to make the first weighing of the bottle containing them.

In making readings of the differential thermometer, the error of parallax may be simply avoided by fixing a white card, of the size of a postal card, with bold graduations in centimeters across it corresponding to those on the thermometer, at a suitable distance behind the latter at the same level,

and placing the eye so that the readings on card and thermometer correspond. The zero reading is given by the difference between the readings on the stem and on the lower bulb, and its value obviously serves as a most useful index of the purity of the solvent. Unsteadiness of reading is caused by too slow boiling.

A pastille of solute is now dropped, from forceps, down the condenser. If it be easy of solution, the reading will at once rise and become constant the moment solution is complete. The ebullioscopic rise is obtained by subtraction of the zero reading from the difference of level now observed. This is later translated into temperature at leisure by the help of a conversion factor extracted from such a table as that given in another communication.<sup>25</sup> It is to be noted that, for fine work, in order to obtain the true conversion factor, one must use as argument the average temperature of the two ends of the thermometer, which is higher than the boiling point previously found by the mercurial thermometer by an increment of temperature corresponding to half the observed ebullioscopic rise. If half the ebullioscopic rise multiplied by the factor selected by a first inspection does not, when added to the boiling point of the solvent, yield a temperature that agrees with the chosen factor, then the factor may be reselected accordingly.

**Case of Volatile Solutes.**—It is generally agreed<sup>29</sup> that, for purposes of straightforward molecular weight determination, the boiling point of an ebullioscopic solvent should lie at least 150° below that of the solute. For this reason, benzil (b. p. 347°) has found favor as a standardizing solute because it may be assumed to be virtually absent from the vapors escaping from its solution in the common ebullioscopic solvents. If, however, the solute be as volatile as naphthalene (b. p. 218°) in boiling carbon tetrachloride or benzene, then one would anticipate that the mixed vapors, on partial condensation, would tend to yield a liquid of the concentration with which they are in equilibrium, namely the concentration of the solution from which they have just escaped. The upper bulb of the differential thermometer might thus be expected to acquire precisely the same temperature as the lower bulb; and, if precaution be taken to minimize condensation on the thermometer, this condition can indeed be approximated. The gross composition of the vapor phase, however, is close to that of the pure solvent, so that if this vapor is completely condensed and caused to lave the upper portion of the differential thermometer, the temperature it acquires in contact with the surrounding vapor is very close to the boiling point of the pure solvent, which is the temperature here desired. In order to provide an adequate laving of this kind, a very simple plan is to embrace the handle of the thermometer, at a point a few centimeters above the upper bulb, with a pair of wires of

<sup>29</sup> Cf. Staehler, Ref. 1.

perhaps 24 S.W.G. twisted together where they meet on opposite sides of the handle, and to direct the two twisted tags so formed upwards in such a way that, by resting against the inner walls of the condenser tube, they may uniformly divert a modicum of the condensate on to themselves and thence to the thermometer. The diagram, Fig. 2, shows these wires, which are prevented from slipping either up or down by reason of the slight constriction in the handle where they are applied. In practice

Fig. 2.

it is useful to employ these wires in all cases, not only because of possible prejudicial volatility of the solute, but to meet the contingency of spattering of the upper portion of the thermometer by minute droplets from a frothing solution. The wires may also very conveniently be bent so that the handle of the thermometer is stationed sufficiently eccentrically within the condenser tube as to allow a very clear passage for the introduction of pastilles. This is indicated in Fig. 2 (b).

**Collected Useful Data.**—In Table I are collected, from diverse sources, certain useful data for a few of the commoner solvents: their normal boiling points; the barometric change,  $dp/dt$ , in mm. of mercury that produces a change of  $1^\circ$  in the boiling point; the density,  $D$ , of the liquid at the boiling point; its change,  $dD/dt$ , per degree of temperature; the ebullioscopic constant,  $K_1$ , for one mole of solute in 100 g. of solvent; the ebullioscopic constant,  $K_2$ , for one mole of solute in 100 cc. of solvent at its boiling point.

TABLE I.  
CONSTANTS USEFUL IN EBULLIOSCOPY.

The values for  $K_1$  are taken chiefly from Staehler's *Handbuch*<sup>1</sup> as an impartial source. We doubt the accuracy of some of these values. It must be remembered that the values determined and adopted by even a single investigator such as Beckmann, for example, have varied from time to time. The matter will be reverted to on another occasion. The change

of the ebullioscopic constants with barometric pressure is of the order of 0.3% per 10 mm. near 760 mm.

**Examples of Results.**—We shall here limit ourselves to a very few typical cases to illustrate merely the consistency of the results obtainable by the use of this apparatus, and their general agreement with the results of others. For a later redetermination of certain ebullioscopic constants, especial purification of materials and other precautions will be required; but for the present purpose the ordinary materials of the laboratory supply-room have proved sufficient. In order to conform to the practice of Beckmann and most others, we have employed in computing our results the well-known simple, if inadequate, relationship  $K_1 = \text{temp. rise} \times \text{mol. wt. of solute} \times \text{wt. of solvent} \div 100 \times \text{wt. of solute}$ .

(a). **Benzil in Benzene.**—Values of the ebullioscopic constant  $K_1$  used by Beckmann<sup>30</sup> were 26.7 (1890), 26.1 (1895), 24.2 (1905), 25.7 (1907, 1914). Drucker<sup>7</sup> found 26.7, Innes<sup>5</sup> 24.1, etc. Beckmann's present accepted value, 25.7, is the mean of two sets of each three measurements with benzil in benzene, as follows: (1) rise, 0.180°, 0.354°, 0.568°, corresponding respectively to  $K_1 = 25.7, 25.6, 25.2$ ; (2) rise, 0.205°, 0.450°, 0.688°, yielding  $K_1 = 25.6, 26.2, 25.7$ . We made two sets of

Fig. 3.

measurements, on different days, as follows: (1) rise, 0.1142°, 0.1820°, 0.2440°, 0.3016°, 0.3661°, corresponding respectively to  $K_1 = 26.6, 26.5, 26.3, 26.2, 26.1$ ; (2) rise, 0.1218°, 0.2126°, 0.3052°, 0.3355°, yielding  $K_1 = 26.4, 26.3, 26.0, 25.9$ . The fourth significant figure has some meaning for our higher readings. From these data, which are shown plotted in Fig. 3, it would appear that the values in each of our sets are rather more self-consistent than those of Beckmann, although obtained with much simpler apparatus; and that 0.1 mm. on the scale of the differential thermometer may be estimated successfully. Our two sets differ from each other, on the average by 0.6%, an error that would be caused by an error of 0.2 cc. in reading 30.0 cc., the approximate volume of benzene employed. As we have learned from many other results, this is the largest value to which this error ever attains; more often the error from this cause is 0.1 or 0.0 cc., averaging well under 0.5% in the result. Aside from possible systematic error, it is the chief single source of error entering into our determi-

<sup>30</sup> Cf. Beckmann, *Z. physik. Chem.*, 88, 23 (1914); 58, 555 (1907).

nations. The details of the observations of Set 1 follow, serving to illustrate the use of conversion factor and to indicate the time consumed.

TABLE II.

(b). Anthracene in Chloroform.—Benzol, alcohol and chloroform are perhaps the three best-studied ebullioscopic solvents, and we chose this example because, in particular, the Sakurai-Landsberger method has been critically studied by Turner<sup>17</sup> who used it to redetermine the constant for chloroform. Of Turner's solutes, anthracene was most readily available to us in reasonably pure form.<sup>21</sup> Because of its ease of decomposition, we do not regard chloroform as so suitable an ebullioscopic solvent as carbon tetrachloride, which covers a similar field of solutes.

In the two sets of experiments for which he gives data, Turner obtained the following results: (1) rise, 0.646°, 0.527°, 0.436°, 0.363°, corresponding respectively to  $K_1 = 40.5, 40.4, 40.5, 40.3$ ; (2) rise, 0.559°, 0.455°, 0.376°, yielding  $K_1 = 38.3, 38.0, 38.5$ . In two sets of experiments we obtained, (1) rise, 0.2672°, 0.3981°, 0.5045°, 0.6213°, yielding  $K_1 = 39.58, 39.42, 39.09, 38.66$ ; (2) rise, 0.3166°, 0.4042°, 0.4792°, 0.5565°, 0.6515°, yielding  $K_1 = 39.90, 39.25, 38.56, 38.59, 38.09$ . Turner averages his two sets at 40.4 and 38.3 respectively,—results discrepant by 5.4%, or 2.7% from their mean. Our results, when plotted, diverge from a straight line drawn through them by 0.56% on the average. It may be said that the impure chloroform used does not show our method to advantage. The unsatisfactory character of chloroform as an ebullioscopic solvent is further indicated by the rather wide variation of the values for the constant employed by Beckmann from time to time, ranging from 35.9 (1895) to 39.0 (1908).

(c). Naphthalene in Ether and in Carbon Tetrachloride.—It is necessary to add these further examples to illustrate the use of an appreciably volatile solute. In a single run in which we added 8 successive quantities of naphthalene to ether of normal boiling point, 34.1°, with consequent elevations of temperature ranging from 0.27° to 2.04°, we obtained values for  $K_1$  of 21.47, 21.43, 21.11, 20.68, 20.39, 20.31, 19.82, 19.77, results which diverge on the average by about 0.33% from a straight line drawn through their plot. If, however, the twisted wires described above were omitted in this case, the results obtained were low and unsatisfactory. It should, perhaps, be added that one does not expect strict rectilinearity in the graph obtained as above; and that, in the case of ether, which has a considerable vapor pressure at the temperature of the condenser, a small correction, under 1% per hour, might be made for progressive loss of solvent by diffusion into the air. A straight line, however, is undeniably a smooth curve, for purposes of reference.

Carbon tetrachloride boils only 141° below naphthalene, thus falling within the forbidden range of 150° referred to above. To secure more copious lavage of the upper

<sup>21</sup> Through the courtesy of the Chemical Department of the Barrett Co.

portion of the thermometer by the condensate in this case, we employed twisted double wires instead of single wires in constructing the drainage mechanism, and opened the ends in contact with the condenser tube so as to form forks, thus withdrawing the condensate from the walls at four points each served by a pair of wires twisted together. This had the effect of raising the zero reading by a few millimeters. Using a solvent of normal boiling point,  $76.2^{\circ}$ , we obtained, from elevations of  $0.1888^{\circ}$ ,  $0.2822^{\circ}$  and  $0.3990^{\circ}$ , values for  $K_1$  of 47.23, 47.89, and 48.46. For computation merely the simple relationship mentioned above was utilized, without correction for volatility of the naphthalene. Benzene as solvent for naphthalene gave results of similar quality, thus demonstrating that usable results may still be obtained even in these somewhat adverse cases.

### Summary.

A simple apparatus for ebullioscopy has been described and illustrated in which is employed a new type of differential thermometer. Most of the sources of experimental error that have influenced the very many earlier forms of ebullioscopic apparatus have here been avoided or so minimized that results consistent to within 0.5% are readily obtained.

## DISTRIBUTION OF CERTAIN DRUGS BETWEEN IMMISCIBLE SOLVENTS.

By W. O. EMERY AND C. D. WRIGHT.

Received July 11, 1921.

Of the many medicinal preparations examined by this laboratory, those containing analgesic and antipyretic agents have been fruitful fields for various lines of investigation. In the isolation of these substances preliminary to their quantitative determination, recourse was frequently had to the use of immiscible solvents, such as aqueous solutions and chloroform, the latter preferably on account of its physical properties and consequent ease of separation and recovery. During the earlier stages of the work, the relative volumes of the solvents, as well as the number of extractions deemed necessary or expedient for complete isolation of the substance sought, were governed largely by empirical considerations, care, being taken, however, that any error of commission should involve an excess rather than a deficiency in organic solvent. In operations with caffeine and antipyrine, for example, substances possessing about equal solubility in chloroform but differing widely in this respect toward water (1 g. of caffeine is soluble in 46 mls, 1 g. of antipyrine on the other hand in less than 1 ml of water), it was assumed that, given like volumes, antipyrine would require a greater number of extractions than caffeine. From preliminary experiments on controls, carried out in the usual way with the

Squibb type of separatory funnel at the room temperature, results were obtained quite different from those anticipated. Thus, in "shaking out" caffeine and antipyrine with chloroform, one such treatment effected the following recoveries from aqueous solutions.

TABLE I.  
RECOVERY OF CAFFEINE AND ANTIPYRINE WITH CHLOROFORM.

Subs. in aq. soln. G.	CHCl <sub>3</sub> . Cc.	H <sub>2</sub> O. Cc.	Caffeine. %.	Antipyrine recovery.

0.1000	50	20	98.1	—
0.1000	50	20 <sup>a</sup>	97.5	96.0
0.1000	50	20 <sup>b</sup>	97.6	—
0.1000	20	20	94.3	94.0
0.1000	20	50	88.1	88.0
0.2000	50	20	—	97.0
0.5000	50	20	—	97.5
1.0000	50	20	—	96.0

<sup>a</sup>Acidified with H<sub>2</sub>SO<sub>4</sub>.

<sup>b</sup>Made alkaline with NaOH.

These findings seemed to indicate that under more nearly ideal conditions involving moderate to low concentrations the distribution ratios of caffeine and antipyrine between aqueous solutions and chloroform might be almost if not quite, identical. The results as above tabulated formed the material for a preliminary communication to the Society at its 49th (Spring) meeting in Cincinnati, and in effect constituted the main incentive to the present study. Owing to the intervening war, however, and the consequent interruption to the normal activities of the Bureau, the final solution of the problem has involved a period of time far in excess of that originally contemplated.

### Caffeine.

In order to gather more precise information relative to some of the factors influencing distribution, such as temperature, concentration, alcohol, acid, alkali and other solutes, several series of experiments were carried out, at first in a so-called constant temperature room at about 19.5°, later in a water-bath maintained at different temperatures, but accurate to within 1°. The pipet employed in this work for withdrawing the chloroform was specially prepared by drawing out the tip of an ordinary 25cc. instrument to a capillary about 10 cm. in length, and adjusting the volume by blowing a small bulb in the stem to 25.00 ± 0.02 cc., as determined by the weight of water delivered.

**Effect of temperature.**—In these and the following experiments, portions of anhydrous caffeine<sup>1</sup> were weighed out in small glass capsules and placed in glass-stoppered bottles of about 150cc. capacity, and then by means of a pipet prepared as above 50 cc. of water and 50 cc. of chloro-

<sup>1</sup> The caffeine used was a well-known commercial brand, recrystallized from water and dried at 100°.

form were added, the bottles were tightly stoppered and placed in a water-bath at the desired temperature, shaken vigorously at intervals and finally allowed to stand until the water and chloroform layers had become clear. Meanwhile, and in order to forestall any possible intake of the aqueous layer preparatory to withdrawal of the chloroform aliquot a minute bulb was blown at the extreme tip of the pipet, sufficiently thin to be easily crushed by gentle pressure against the bottom of the container, 25 cc. of the chloroform was withdrawn and run into a tared beaker. The solvent was then evaporated by an air blast and gentle heat, and the beaker and contents were weighed. The difference in weight multiplied by two<sup>2</sup> represents the amount of caffeine in the chloroform layer. The results obtained in the first extractions are given below.

TABLE II.  
EFFECT OF TEMPERATURE UPON EXTRACTION WITH CHLOROFORM.

Total caffeine. G.	Temp. °C.	Caffeine in 25 cc. of CHCl <sub>3</sub> . G.	Recovery. %.
0.5000	12	0.2407	96.3
0.5000	21	0.2383	95.3
0.5000	30	0.2357	94.3
0.5000	40	0.2330	93.2

It is evident that a low temperature is favorable to the extraction of caffeine from water by means of chloroform.

**Effect of concentration.**—A series of experiments similar to the above was carried out in the constant-temperature room at about 19.5°, but with varying concentration of caffeine, with the following results.

TABLE III.  
EFFECT OF CONCENTRATION OF CAFFEINE UPON EXTRACTION.

Total caffeine. G.	Caffeine in 25 cc. of CHCl <sub>3</sub> . G.	Recovery. %.
0.1000	0.0480	96.0
0.2000	0.0958	95.8
0.5000	0.2376	95.0
1.0000	0.4702	94.0
2.0000	0.9240	92.4
2.5000	1.1400	91.2
5.0000	2.1710	86.8

The above findings show that the distribution is more favorable to the chloroform in dilute solution, *i. e.*, that the recovery of caffeine decreases with increase in concentration in water.

**Effect of alcohol.**—Since U. S. P. chloroform contains 0.6 to 1.0% of alcohol, it was of interest to determine how much, if at all, distribution

<sup>2</sup> On the assumption that the volume of the chloroform layer is the same as that introduced. This is of course not strictly true, since the caffeine increases the volume slightly. Another conceivable source of error would be in a change in the volumes of water and chloroform on shaking, owing to mutual solubility, but tests indicated that this is inappreciable.

would be influenced by its presence. A similar series of experiments was therefore carried out, using instead of pure chloroform a mixture containing 1% of alcohol, prepared by diluting 5 cc. of absolute alcohol to 500 cc. with chloroform. These experiments were likewise conducted at the uniform temperature of 19.5°.

TABLE IV.

## EFFECT OF ALCOHOL IN CHLOROFORM UPON EXTRACTION OF CAFFEINE.

Total caffeine. G.	Caffeine in 25 cc. of CHCl <sub>3</sub> . G.	Recovery. %.
0.1000	0.0483	96.6
0.2000	0.0964	96.4
0.5000	0.2403	96.1
1.0000	0.4752	95.0
2.5000	1.1500	92.0
5.0000	2.1810	87.2

These percentages are in all probability somewhat too high, due to the fact that most of the alcohol passes into the water on shaking, with consequent diminution of the chloroform layer, the 25cc. portion removed representing slightly more than  $\frac{1}{2}$  of the total volume. A more accurate method would undoubtedly be to use a 1% solution of alcohol in water, and alcohol-free chloroform.

**Effect of Acid.**—The feebly basic character of caffeine makes the study of its extraction from acid solutions of considerable interest. Accordingly, experiments were undertaken to determine its distribution between pure chloroform and *N* sulfuric acid, 50 cc. of each reagent being taken. The temperature in this series was maintained at 20.4°.

TABLE V.

## EFFECT OF ACID SOLUTIONS UPON EXTRACTION OF CAFFEINE.

Total caffeine. G.	Caffeine in 25 cc. of CHCl <sub>3</sub> . G.	Recovery. %.
0.1000	0.0455	91.0
0.2000	0.0908	90.8
0.5000	0.2255	90.2
1.0000	0.4463	89.3
2.5000	1.0795	86.4
5.0000	2.0410	81.6

These results are what might be reasonably expected, showing as they do a somewhat less efficient extraction from an acid solution. Beal and Lewis,<sup>3</sup> on the other hand, operating on 0.2g. samples of caffeine in 25cc. portions of 0.5 *N*, 0.25 *N* and 0.125 *N* sulfuric acid with 20cc. portions of chloroform, report higher recoveries for caffeine than were obtained from a similar operation on a neutral aqueous solution. The accompanying Fig. 1 affords a graphical representation of results obtained in the above three series.

<sup>3</sup> Beal and Lewis, *J. Am. Pharm. Assoc.*, 5, 824 (1916).

**Effect of other solutes.**—The influence of various solutes, as ammonium hydroxide, sodium hydroxide, sodium acetate, sodium salicylate, sucrose, and citric acid, was observed in a few preliminary experiments with the Squibb type of separatory funnel at a temperature of about 25°.

TABLE VI.  
EFFECT OF OTHER SOLUTES UPON EXTRACTION OF CAFFEINE.

Total caffeine. G.	CHCl <sub>3</sub> . Cc.	Cc.	Aqueous solvent.	Recovery. %.
0.5000	25	20	H <sub>2</sub> O + 5 cc. of 28% NH <sub>4</sub> OH	94.1
0.5000	25	20	H <sub>2</sub> O + 5 cc. of 5% NaOH	95.5
0.5000	50	50	mol. Na acetate sol.	96.6
0.5000	25	25	mol. Na salicylate sol.	20.7
0.5000	25	25	0.1 mol. Na salicylate sol.	82.0
0.2000	50	50	mol. sucrose sol.	96.4
0.5000	25	25	mol. citric acid sol.	85.2

Of these and other solutes examined in this manner, sodium salicylate appears to have by far the greatest effect on the distribution ratio, due apparently to the formation of some molecular compound not readily yielding its caffeine component to the chloroform.

**Constant temperature bath.**—In order to control temperature conditions more accurately, a tank was constructed of sheet copper, elliptical in form, with double walls inclosing an insulating space 25 mm. thick, packed with "mineral wool." The inside dimensions were, length 70 cm., width 50 cm. and depth 45 cm., thus affording a capacity of about 150 liters. A tubular vertical shaft at the lower end carried, in addition to a set of stirring blades, a curved cross tube (hydraulic tourniquet or Barker's mill type), and a glass mercury-cup seal at the top similar to that illustrated by Hudson,<sup>4</sup> which, being connected by rubber tubing

Fig. 1.

with a jacket of glass tubing 38 mm. in diameter containing either a pipet or buret as the experiment required, served as a pump for drawing water from the bath, and thus gave vigorous circulation and maintained the pipet (or buret) with its contents at the same temperature. A temperature control within 0.01° was secured by means of a hydrogen-sealed mercury thermo-regulator of the general type described by Clark,<sup>5</sup> heat being supplied by two 100-watt carbon lamps submerged in the water and controlled by a relay in the usual manner, which served to maintain the bath at 25° when the room was not below 20°, and also to illuminate the interior. In the event of temperatures lower than 20°, additional heat could be supplied by means of an auxiliary resistance coil. The temperature of 25° was selected because of its convenience and close approximation to ordinary laboratory conditions, also because it is the standard of the U. S. Pharmacopeia. For convenient observation

<sup>4</sup> Hudson, *THIS JOURNAL*, 30, 1572 (1908).

<sup>5</sup> Clark, *ibid.*, 35, 1889 (1913).

of the temperature, a Beckmann thermometer was used, the reading corresponding to 25.00° being determined by comparison with two calibrated (Bureau of Standards) thermometers reading to 0.01°. Midway of the tank was a submerged horizontal shaft so geared as to rotate about 20 times per minute, carrying spring clamps suitable for holding bottles. These were of the type known as "German tinctures", having flat-topped glass stoppers. They were very carefully tested for leakage before use. A basket at the side of the tank was provided for allowing the bottles to stand submerged to the necks for any period of time desired.

### Solubility of Caffeine.

In connection with the work on distribution, it was deemed advisable to acquire additional information on the solubility of caffeine in both water and certain aqueous solutions, the more so since the values obtained in some of the earlier experiments were unquestionably too high, due to supersaturation. Considerable difficulty was experienced in overcoming this condition. Starting with anhydrous caffeine, a much larger apparent solubility is obtained, hence it is necessary to convert the substance into its hydrated form by solution and redeposition before a true equilibrium is established. If sufficient caffeine is originally taken, such supersaturated solutions yield a dense mass of hydrated crystals from which no solution can be separated conveniently. The anhydrous form, therefore, has a much greater solubility, but is unstable under these conditions. The method as finally developed for caffeine is essentially that outlined below.

TABLE VII.  
SOLUBILITIES OF CAFFEINE IN VARIOUS AQUEOUS SOLUTIONS.

Solvent.	Caffeine in 10 cc.	
	G. <sup>a</sup>	G.
Water .....	0.2133	0.2072
	0.2199	0.2063
	0.2183	0.2074
	0.2316	0.2076
	mean	0.2071
<i>N</i> sulfuric acid.....	0.3495	0.3361
	0.3526	0.3351
<i>N</i> citric acid.....		0.6406
		0.6417
<i>N</i> potassium bromide.....		0.2135
		0.2137
2.5 <i>N</i> potassium bromide.....		0.2031
		0.2041
<i>N</i> sodium salicylate .....	2.282	2.221
	2.278	2.222
	2.274	2.222
0.1 <i>N</i> sodium salicylate .....		0.4930
		0.4913
<i>N</i> sodium benzoate .....		1.545
		1.527
		1.511
0.1 <i>N</i> sodium benzoate.....		0.3431
		0.3414

<sup>a</sup> These values are unquestionably too high, being the result of earlier operations not strictly in accord with the above method.

**Method.**—Bottles containing the solvent and an excess of caffeine were allowed to stand for 3 days (or until the separation of crystals appeared to be complete), then rotated for 2 hours, and allowed to stand for another 2 hours in the bath. Portions of the clear solution were thereupon withdrawn by means of the water-jacketed pipet referred to above, and, in the case of water, run directly into tared beakers for evaporation, or into separatory funnels for extraction of the caffeine with chloroform from the other aqueous media employed.

The relatively high values obtained in certain of these experiments, notably in the case of sodium salicylate and benzoate, point to the existence of molecular compounds having a higher solubility than caffeine itself. The existence of such compounds has already been assumed by Daudt,<sup>6</sup> but so far as known no satisfactory proof has as yet been adduced.

**Cryoscopic experiments.**—In order to obtain further information on the increased solubility of caffeine in salicylate and benzoate solutions, and on the nature of the combinations existing therein, experiments were undertaken with solutions containing these solutes singly and in admixture, using the ordinary Beckmann freezing-point apparatus. The results obtained are given below, being averages of several determinations.

TABLE VIII.  
FREEZING-POINT DEPRESSIONS.

Solute in 100 cc.	Depression. °C.	
Caffeine, 1 g. ....	0.08	
Sodium salicylate, 1 g. ....	0.23	
Caffeine + sod. salicylate, each, 1 g. ....	0.233	(0.31°) <sup>a</sup>
Sodium salicylate, 0.824 g. <sup>b</sup> ....	0.20	
Caff. 1 g. + sod. salicylate, 0.824 g. ....	0.20	(0.28°) <sup>a</sup>
Sodium benzoate, 0.742 g. <sup>b</sup> ....	0.22	
Caff. 1 g. + sod. benzoate 0.742 g. ....	0.26	(0.30°) <sup>a</sup>

<sup>a</sup> Sums of the depressions of the single solutes.

<sup>b</sup> These amounts represent the molecular equivalent of 1 gram of caffeine.

The above values clearly show that, in the case of sodium salicylate solutions, the addition of a molecular equivalent of caffeine produces no further depression of the freezing point; and, in the case of sodium benzoate solutions, the addition of a molecular equivalent of caffeine produces only about  $\frac{1}{2}$  the depression to be expected. These results are in apparent harmony with those obtained in the solubility tests, and, as will later appear, in the distribution studies.

**Distribution.**—In the experiments on caffeine enumerated below, the chloroform and aqueous solutions were brought to 25° by standing in the constant-temperature bath; then, by means of the jacketed pipets referred to previously, were measured into bottles containing weighed amounts of caffeine, the aqueous layer being introduced first in order to minimize loss by evaporation. The bottles were tightly stoppered and, to insure that they remained so, cork discs were laid over the stoppers and spring clamps applied to hold them firmly in place. After rotating for two hours, and standing for about the same period in the bath as in the case of the solubility experiments, half aliquot portions of the chloroform layer<sup>2</sup> were with-

<sup>6</sup> Daudt, *Pharm. Ztg.*, 32, 376 (1887).

drawn by jacketed capillary-tipped pipets and run into tared beakers for evaporation. In the cases where salts were present, an additional precaution was taken of washing with a small portion of water in a separatory funnel, the chloroform aliquot removed, the water then being exhausted of any dissolved caffeine by two small portions of chloroform, and all of the latter solvent evaporated in a tared beaker. The results obtained in the several series are as follows.

A graphical representation of these data is given in Fig. 2.

Fig. 2.

from which the relatively slight effect of potassium bromide, as contrasted with that of the other solutes, is immediately apparent. Since the percentage error in the case of small amounts of caffeine is naturally much greater than when larger quantities are employed, the exact course of the line at such low concentrations becomes difficult of determination.

### Antipyrine.

The procedure followed in studying the distribution of antipyrine between absolute chloroform and aqueous solutions was in the main quite similar to that described for caffeine, with this difference, however, that instead of weighing the recovered product directly the residues obtained

on evaporation of the chloroform half-aliquots, which are withdrawn after rotation in the constant-temperature bath, were titrated either as a whole (in alcoholic solution with iodine in the presence of mercuric chloride), or as aliquots, according to the method of Bougault.<sup>7</sup> As a preliminary thereto, a few tests were carried out in Squibb separatory funnels at 25° with U. S. P. chloroform and aqueous solutions of sodium acetate, potassium bromide, sucrose and sulfuric acid. The results obtained in these operations are indicated below.

<sup>7</sup> Bougault, *J. Pharm. chim.*, 1, 858 (1898).

Fig. 3 is a graphical representation of the results shown in the last three series.

A study of these data shows that there is no such tendency to the formation of double salts as obtains in the case of caffeine (cf. Series IV and VIII). There is, on the other hand, a far greater depression in the percentage of antipyrine extracted from *N* sulfuric acid, when compared with that from purely aqueous solution, due presumably to difference in basicity.

### *p*-Acetoxy-acetanilide.

As a preliminary to more refined work on the behavior of this substance when agitated with water and U. S. P. chloroform, a few experiments were

carried out in the usual way with separatory funnels at a temperature of about 20°. The material employed in this and all subsequent work was a carefully recrystallized product melting at 150–151°. The results obtained as also the quantities of solute and solvents involved, are indicated below.

Fig. 3.

TABLE XII.

RECOVERY OF <i>p</i> -ACETOXY-ACETANILIDE.				
Total solute. G.	Water. Cc.	Chloroform. Cc.	Recovery in 1st ext'n.	
			G.	%.
0.1000	25	25	0.0891	89.1
0.1000	25	25	0.0891	89.1
0.1000	10	25	0.0953	95.3
0.1000	25	10	0.0776	77.6

These results reflect a somewhat lower distribution ratio than obtains for either caffeine or antipyrine under like treatment.

**Solubility.**—Preparatory to a more exact study on distribution, some information was deemed essential with respect to the solubility of *p*-acetoxy-acetanilide, notably in water and absolute chloroform. The method followed in this case was quite similar to that described under caffeine, with the exception that the bottles containing the solvent and excess of solute were rotated immediately upon receipt of their respective charges at 25° in the constant-temperature bath. The amounts of solute found in these experiments were as follows.

SOLUBILITY OF <i>p</i> -ACETOXY-ACETANILIDE.		—Solute in 10 cc.
Solvent.		G.
Water.....		0.0237
		0.0238
		0.0240
	mean	0.0239

	mean	0.3250

negligible amount of the solute in question, as also in calculating the percentage of substance originally present in solution from data yielded by the first extraction. However attractive in principle these procedures may appear, it must be equally apparent to anyone skilled in the art that their general adoption could yield satisfactory results only under the most ideal conditions. In their practical application to many of the problems peculiar to drug analysis, one would certainly encounter grave difficulties, as in the formation of emulsions of greater or less persistence, which prevent any sharp separation of the two liquid media, more particularly, however, in cases involving two or more solutes and the possible existence of molecular compounds, which, as has been noted in the work above described, markedly affect the distribution.

### Summary.

1. Studies have been made of the effect of temperature and concentration on the distribution of caffeine between water and chloroform.
2. The effect of the presence of other solutes in the aqueous layer on distribution has been determined at 25°.
3. The solubility of caffeine in water and certain aqueous solutions has been measured at 25°.
4. Further proof of the existence of molecular compounds of caffeine with sodium salicylate and sodium benzoate in aqueous solution has been obtained by cryoscopic measurements.
5. The distribution of antipyrine has been determined under similar conditions.
6. The solubility of *p*-acetoxy-acetanilide in water and chloroform has been measured at 25°. Its distribution between water and chloroform has likewise been determined.
7. Comparison of the distribution curves for caffeine and antipyrine between water and chloroform confirms the earlier assumption that the distribution ratios of these substances are nearly if not quite identical.

## THE HEAT OF COAGULATION OF FERRIC OXIDE HYDROSOL WITH ELECTROLYTES.<sup>1</sup>

BY FREDERICK L. BROWNE AND J. HOWARD MATHEWS.

Received July 15, 1921.

### Introduction.

The pioneers in the field of colloid chemistry, for example Selmi,<sup>2</sup> Graham,<sup>3</sup> and Linder and Picton,<sup>4</sup> attached great significance to the fact that they found no measurable change in temperature accompanying the formation or the coagulation of colloidal dispersions. The formation of a true solution always involves a heat change which it has been customary by way of loose illustrative analogy to regard as being similar in nature to the thermal effect involved in the change of state of a pure substance. In passing into solution, the solid absorbs the analogs of the heats of fusion and of vaporization in order to attain a condition which in many ways resembles that of a gas. In addition there frequently are other phenomena involved such as hydration, ionization and hydrolysis, also associated with energy changes which are usually positive and may more than counter-balance the first effect. But in general the heat of solution of hydrous neutral salts and of non-electrolytes is negative and of the order of some thousands of calories per gram equivalent.

In considering the theory of colloidal dispersion a knowledge of the energy changes involved is important. Many writers maintain that the phenomena of colloidal dispersion are identical with those of true solution save in the final size of the particles; that, in other words, true solution is merely the limiting case of colloidal dispersion. This being the case, colloids must have a "heat of peptization" of the same nature as the heat of crystalloidal solution. It is reasonable to assume that these heat effects arise from the work required to subdivide the solid and are at least roughly proportional to the specific surface developed by the dispersed phase. Taking the diameter of the molecules of a certain substance as  $0.1\mu\mu$  and the diameter of its colloiddally dispersed particles as  $10\mu\mu$ , the "heat of peptization" should then be about one hundredth part of the heat of solution, that is, of the order of some tens of calories per gram equivalent. On the other hand, if crystalloidal solution takes place by a process different from that of colloidal dispersion, we should not

<sup>1</sup> Abstract of a thesis submitted by F. L. Browne to the Faculty of the University of Wisconsin in partial fulfilment of the requirements for the degree of Doctor of Philosophy.

expect to find any relation between heat of solution and "heat of peptization."

It is to be understood that by the term "heat of peptization" is meant merely the heat change involved in the subdivision of the solid phase and it is to be distinguished from the heat of wetting, heat of adsorption of substances in solution, or other heat effects due to the presence of substances in true solution. The converse of the "heat of peptization," *i. e.*, the energy change involved in the precipitation of the colloidal dispersion, will be called the "heat of coagulation."

Doerincel<sup>5</sup> has pointed out that the small amount of literature concerning the heat of coagulation of colloids is contradictory and inconclusive. He found that measurable amounts of heat are evolved on coagulating ferric oxide and silica hydrosols with electrolytes; his sols, however, contained large amounts of electrolytes and the magnitude of the heat effect on coagulation was greatly decreased on partly removing these by dialysis, although he did not seem to attach much significance to this fact. Kruyt and van der Spek<sup>6</sup> extended these experiments to the coagulation of arsenous sulfide hydrosol, finding that no measurable heat change accompanied the coagulation in this case. They concluded that the heat effects during the coagulation of ferric oxide sol are to be attributed to changes in the degree of hydration of the ferric oxide. For the case of arsenous sulfide they pointed out that no measurable amount of heat could be produced by interaction of the electrolytes in the sol and in the coagulant, but they completely ignored this possibility in the case of ferric oxide sol.

### Experimental Methods.

The determination of the heat changes accompanying the coagulation of colloids presents unusual difficulty because the magnitude of the heat effect per unit weight of dispersed phase is small, and the concentration of the colloid is usually low, consequently the temperature change to be measured is very small.

The apparatus employed was the familiar "submarine" type of the Richards adiabatic calorimeter.<sup>7</sup> The calorimeter vessel was a silver beaker of 700cc. capacity. This was placed in the "submarine" and the whole immersed in a bath of water constituting the "environment." The water of the environment was kept in rapid circulation by means of two powerful propeller stirrers, and its temperature could be very quickly altered by means of an electrical heating coil or by opening a valve admitting ice-water. A 4-junction copper-constantan thermo-element, connected to a sensitive galvanometer registering by means of a spot of light on a ground-glass scale, was placed with one limb in the liquid in the calorimeter vessel, the other in the environment, so that the difference in temperature between the two could be read at all times. Through-

out an entire experiment this temperature difference was maintained within  $0.006^{\circ}$  of the desired value; after a sudden change in the temperature of the contents of the calorimeter amounting to  $1^{\circ}$  (very much larger than the temperature changes actually encountered) this temperature difference between environment and calorimeter contents could be restored to the desired value within 15 to 30 seconds.

The sample of the colloid to be coagulated was placed in the calorimeter vessel. Within this was suspended a silver cylinder closed at the bottom by a sheet of rubber dam held in place by a rubber band. The solution of the electrolyte used as coagulant was placed in this inner cylinder, or "mixing chamber." By means of mechanical stirrers, both the colloid and the coagulant were vigorously agitated. When the entire contents of the calorimeter had come to the same temperature, the temperature of the environment was so adjusted with respect to that of the calorimeter contents that the temperature of the latter remained constant. This was the case when the environment was very slightly cooler than the calorimeter contents, so that there was a loss of heat to the environment just equal to the heat generated by the operation of the mechanical stirrers. When this relation between environment and calorimeter temperatures had been found and the temperature of the calorimeter contents remained constant for a period of 10 minutes or more, the colloid and coagulant were mixed by operating a trigger which slipped off the rubber band holding the rubber bottom of the mixing chamber in place, and the entire silver cylinder was lowered slightly so as to be completely submerged in the mixed liquids in the calorimeter vessel. The same relation between the calorimeter and environment temperature was maintained until the calorimeter temperature again became constant, giving the end-point of the reaction.

The temperature of the calorimeter contents was measured by means of a Leeds and Northrup platinum resistance thermometer and thermometer bridge, the readings being estimated to  $0.0001^{\circ}$ . Instead of determining the water equivalent of the calorimeter and the specific heats of the liquids used, at the beginning of each experiment a measured quantity of electrical energy was converted into heat by means of a resistance coil submerged in the liquids in the calorimeter, and the resulting rise in temperature measured. This gave the amount of energy required to raise the calorimeter and contents  $1^{\circ}$ , and by multiplying this by the temperature change resulting upon mixing the liquids, the amount of heat liberated was obtained.

Under certain circumstances the method of operation was not as simple as described above. The stirring of the liquids in the calorimeter generated a certain amount of heat in consequence of which the temperature of the environment was maintained slightly below that of the liquids in the calorimeter in order that this amount of heat might be lost to the environment. If on coagulating the sol the resistance to the stirrers was greatly increased, heat was generated more rapidly than it was being lost to the environment, and at the end of the reaction the temperature did not remain constant, but rose slowly. In a number of the experiments in which the coagulum was especially gelatinous and bulky this proved to be the case. The difficulty was met by plotting the temperature-time curve for the 20 to 30 minutes following the mixing of the liquids. The temperature rose very rapidly for 1 or 2 minutes, then more slowly, and finally at a constant rate of the order of  $0.0002^{\circ}$  per minute. This constant rise in temperature was due to the added amount of heat generated as a result of the extra resistance to the stirrers. The straight line forming the last part of the temperature-time curve was extrapolated back to the time of mixing the liquids and the corresponding temperature taken as the end-point of the reaction.

The heat effect observed on mixing a sample of a sol with a solution of an electrolyte in this way included the heats of dilution of the sol with the

water in the electrolyte solution, and of the electrolyte solution with the water in the sol. In separate experiments, another sample of the sol was diluted with a volume of water equal to that of the coagulant, and another portion of the coagulant with a volume of water equal to that of the sol. These heats of dilution were then subtracted from the total heat effect on mixing sol and coagulant to give the "heat of coagulation."

Under the most favorable conditions the temperature difference was measured with an accuracy of  $0.0002^\circ$ , so that, allowing a similar amount for imperfect adiabaticity, the heat change was determined within about 0.25 gram calorie, corresponding to about 0.5 calorie per gram equivalent of ferric oxide for the more concentrated sols used. Where the coagula were very bulky and gelatinous, however, the errors were greater, so that the results cannot be relied upon closer than 1 or 2 calories per gram equivalent of ferric oxide.

#### Preparation of the Hydrosols.

Graham's method of mixing ferric chloride and ammonium carbonate solutions and dialyzing was used for the preparation of the ferric oxide hydrosols. 400 g. of ferric oxide was dissolved in a liter of water, filtered, and then 1000 cc. of a saturated solution of ammonium carbonate added slowly with constant stirring. Nine liters having been prepared in this way, it was dialyzed through collodion sacks. As soon as the purification had proceeded far enough to permit heating the sol to  $80^\circ$  without causing partial coagulation, the method of hot dialysis<sup>3</sup> was used. Experiment showed that the heat of coagulation of sols of the same purity prepared by hot dialysis and by cold dialysis is the same.

The sols were analyzed for ferric oxide and for chlorine. Following the nomenclature of Neidle, the ratio of gram equivalents of ferric oxide per liter to gram equivalents of chlorine per liter is called the "purity" of the sol.

#### Results.

**Heat of Dilution of Ferric Oxide Hydrosols.**—A 9-liter batch of colloid having been prepared, it was given a number for purposes of identification, and subjected to dialysis. As it attained different degrees of purity, samples were withdrawn, analyzed, and divided into portions for measurements of heats of coagulation and of dilution. Table I gives the data obtained on dilut-

Fig. 1.—The heat of dilution per g. equiv. of  $\text{Fe}_2\text{O}_3$  as a function of the purity of the sol for ferric oxide hydrosols containing, respectively, 1.4 and 0.6 g. equiv. of  $\text{Fe}_2\text{O}_3$  per liter. The marked heat effects with the less pure sols disappear when the purity exceeds 22.

<sup>3</sup> Neidle and Barab, *THIS JOURNAL*, 39, 71 (1917).

ing 340cc. portions of such sols with 240 cc. of water. The first column gives the number of the sol, the second the purity, the third the content of ferric oxide and of chlorine, the fourth the observed

heat effect, and the fifth the heat effect in calories per gram equivalent of ferric oxide and in calories per gram equivalent of chlorine in the sol. For each purity, a curve was drawn showing the heat of dilution per gram equivalent of ferric oxide as a function of the concentration of the sol. By selecting a line of constant concentration and reading its intersections with the curves for the different purities, the data were obtained for Fig. 1, which gives the heat of dilution per gram equivalent of ferric oxide as a function of the purity. Fig. 2 is drawn on the assumption that the heat effects are due entirely to the electrolytes in the sol. Taking the chlorine content as the measure of these electrolytes, the heat of dilution per gram equivalent of chlorine is plotted against the concentration of chlorine in the sol. In this figure is shown also the heat of dilution of ferric chloride solutions of varying concentration, the data for which are given in Table II.

TABLE II.  
HEAT OF DILUTION OF FERRIC CHLORIDE.  
360 cc. of ferric chloride solution diluted with 255 cc. of water.

Concentration $\text{FeCl}_3$ g. equiv. per liter.	Heat effect calories.	Heat of dilution per g. equiv. $\text{FeCl}_3$ .

0.515	+18.7	+100.8
0.257	+ 2.9	+ 31
0.129	- 1.8	- 38
0.064	- 2.7	-116
0.032	- 2.2	-191
0.016	- 1.1	-192
0.008	- 0.3	- 90

Heat of dilution of a solution containing 0.0643 g. equiv. of  $\text{FeCl}_3$  and 0.0625 g. equiv. of  $\text{NH}_4\text{Cl}$  per liter was -1.95 calorie.

The freshly prepared hydrosols have a positive heat of dilution which rapidly decreases in magnitude as the dialysis proceeds, soon reaching zero and then becoming negative, passing through a minimum at a purity between 7 and 8, finally rising to zero beyond a purity of 21 or 22. Fig. 2 shows that ferric chloride solutions behave similarly on dilution. This suggests that the heat effect observed on dilution of the colloid may be due to the presence of ferric chloride. An observation by Neidle<sup>8</sup> lends support to this view. He noted that when a sol with a purity less than 21 is coagulated with sodium sulfate, for example, and the supernatant liquid tested for ferric ion by means of thiocyanate, a positive test results, but with sols having a purity greater than 21 the test is negative.

The curves in Fig. 2 confirm this assumption. If all the chlorine in the sol represented ferric chloride and the dilution of this salt were the only cause of a heat

Fig. 2.—The heat of dilution per g. equiv. of Cl in the sol plotted against the concentration of Cl in the sol for ferric oxide sols containing, respectively, 1.4 and 0.6 g. equiv. of  $\text{Fe}_2\text{O}_3$  per liter, together with the heat of dilution of ferric chloride solutions of varying concentration. The similarity in the shapes of these curves suggests that the heat effects on diluting ferric oxide sols are due to the ferric chloride contained in them.

effect, the curves for the colloids and for the dilution of ferric chloride would coincide. But the first of these assumptions is known to be incorrect, for part of the chlorine represents ammonium chloride, a by-product of the reaction by which the sol was prepared, and a part probably represents hydrochloric acid. In addition the presence of the colloidal ferric oxide undoubtedly results in the adsorption of a part of the electrolytes present. The present state of our knowledge of ferric oxide sol does not permit us to make corrections for these factors quantitatively, but considering them qualitatively we see that, since the heat of dilution of ammonium chloride or of hydrochloric acid in the concentrations present is negligible, the curves for the colloids tend to coincide with that for the ferric chloride solutions. The close similarity in the shapes of the curves together with the fact that after the sols have reached a purity of 21 the heat of dilution is zero, show definitely that the observed heat effects are to be attributed to the electrolytes present in the sol.

When a ferric chloride solution is diluted in the calorimeter there results first a rapid evolution or absorption of heat, depending upon the concentration of the solution used, followed by a slow rise in temperature of the order of magnitude of  $0.001^\circ$  per minute. This secondary evolution of heat continues for hours, but during the first 15 or 20 minutes at least it takes place at a constant rate. For present purposes we are interested only in the first large heat change. The temperature of the calorimeter contents was therefore taken at intervals and plotted against the time. The curve became a straight line within a few minutes after the dilution took place, and was extrapolated back to the time of mixing to give the final temperature of the contents of the calorimeter.

Goodwin<sup>9</sup> observed a similar phenomenon in his study of the conductivity of ferric chloride solutions. When a ferric chloride solution is quickly diluted and the conductivity measured at intervals, this is found to increase slowly for a number of hours. Moreover, the diluted solutions which are at first nearly colorless gradually take on the red color characteristic of colloidal ferric oxide. Goodwin explained the phenomenon on the basis of the theory that the hydrolysis of ferric chloride takes place in two steps.

The first step is an instantaneous reaction, but the second requires time. The second step resembles a supersaturation phenomenon in that it proceeds more readily if the solution is first "seeded" with ferric oxide sol, the particles of which are assumed to act as nuclei for the further condensation of ferric oxide.

These experiments on the heat of dilution of ferric chloride solutions

<sup>9</sup> Goodwin, *Phys. Rev.*, 9, 251 (1896); 11, 193 (1900).

indicate that Reaction 1 is strongly endothermal and Reaction 2 exothermal. It should be noted, however, that the thermal data confirm the conclusion that the hydrolysis takes place in two steps, the first a rapid and the second a slow reaction, but do not add any conclusive evidence regarding the nature of the hypothetical intermediate product which Goodwin assumed

to be  $\text{FeOH}^+$ . From the high heat of formation of water from its ions and the exothermal character of Reaction 2 we should prefer to write it in such a way as to involve the decomposition of fewer molecules of water.

**Heat of Mixing of Ferric Chloride with Electrolytes.**—The stock ferric chloride solution was 1.029 *N* and the ratio of equivalents of iron to equivalents of chlorine was 1.000. From this a series of dilutions was prepared, and the heat effect determined on mixing 360 cc. with 255 cc. of the electrolyte solution used for the coagulation of the ferric oxide sols.

Fig. 3.—The heat of mixing of solutions of electrolytes with solutions of ferric chloride of varying concentration.

The electrolytes used were sodium oxalate, sodium sulfate, sodium chloride, potassium ferricyanide, sulfuric acid, and sodium hydroxide. With each of these coagulants, the influence of the following factors on the heat of coagulation was determined: (1) the concentration of the hydrosol; (2) the purity of the sol; (3) the concentration of the coagulant.

A large batch of colloid having been prepared and subjected to dialysis, samples were withdrawn at various purities. With each sample a series of dilutions was prepared and observation made of the heat effect accompanying the coagulation with the electrolyte solution being studied. From the total heat effect observed were subtracted the heats of dilution of the sol and of the coagulant to obtain the heat of coagulation. Plotting the results gave a family of curves for sols of the different purities showing

From this were subtracted the heats of dilution of 360 cc. of the ferric chloride with 255 cc. of water, and of 255 cc. of the electrolyte solution with 360 cc. of water, the difference being the heat of mixing of the ferric chloride and the electrolyte solution. The data are given in Table III and Fig. 3.

The very significant values for the heats of mixing are undoubtedly to be explained by the influence of the electrolytes upon Reaction 1 in the hydrolysis of the ferric chloride. Moreover, in the coagulation of ferric oxide sols having a purity less than about 22 this heat of mixing of the electrolyte with the ferric chloride present in the sol will be expected to play an important part.

**Heat of Coagulation of Sols with Electrolytes.**—Since ferric oxide hydrosol is positively charged, the anions are the effective ions in coagulation.

the heat of coagulation as a function of the concentration of the sol. Selecting lines of constant concentration and reading their intersections with the curves for the different purities gave the data from which curves showing the heat of coagulation as a function of the purity, the concen-

tration of the sol remaining constant, were obtained. Finally, using a sample of colloid having constant purity and concentration, the heat of coagulation with solutions of the electrolyte in varying concentration was measured, correction being made as usual for the heats of dilution of the sol and of the electrolyte. The concentration of the coagulants was varied over wide limits, the most dilute solution lying well below the limiting concentration so that the sols were not coagulated by them.

Tables IV to VI give the data for the heat of coagulation of sols of different purity and concentration with the six different electrolytes. The first column gives the purity of the sol, the second the concentration of ferric oxide and of chlorine in the sol, the third the observed heat effect, the fourth the heat of dilution of the sol and of the coagulant, and the fifth the heat

<sup>a</sup> The sols did not coagulate in these experiments.

of coagulation per gram equivalent of ferric oxide and per gram equivalent of chlorine in the sol. Fig. 4 shows the heat of coagulation per gram equivalent of ferric oxide as a function of the concentration of the sol in the case of 0.1 *N* sodium oxalate as coagulant. The corresponding curves for the other electrolytes are similar in character. In Fig. 5 the

Fig. 5.—The heat of coagulation with 0.1 *N*  $\text{Na}_2\text{C}_2\text{O}_4$  of ferric oxide sols containing, respectively, 0.6, 0.8, 1.0 and 1.4 g. equiv. of  $\text{Fe}_2\text{O}_3$  per liter, as a function of the purity of the sol. At the higher purities the heat effects become very small.

heat of coagulation per gram equivalent of ferric oxide is plotted against the purity for sols containing 0.6, 0.8, 1.0, and 1.4 gram equivalents of ferric oxide per liter, the coagulant being 0.1 *N* sodium oxalate. Fig. 6 gives the heat of coagulation per gram equivalent of ferric oxide as a function of the purity for all six electrolytes used, the concentration of the sol being 1.0 gram equivalent of ferric oxide per liter.

These curves show in a striking manner that the heat effects are large only when the sol contains large amounts of electrolytes. As these are removed by dialysis, the heat effect falls off very rapidly, eventually falling within the experimental error at a purity of about 23

in the cases of sodium chloride and potassium ferricyanide as coagulants. With sodium sulfate and potassium oxalate at this purity the heat of coagulation is small, but still measurable. The curves could not be carried much farther in the direction of greater purity, however, because of the experimental difficulty of preparing such concentrated sols of high purity, and also because the coagulum formed from sols of such high purity becomes so bulky and gelatinous that the contents of the calorimeter can no longer be adequately stirred, and the generation of heat by friction with the stirrers becomes large enough to introduce serious error.

Clearly the observed heat effects are due to the presence of the electrolytes in the sol and not to the change in the dispersity of the ferric oxide during coagulation. This is shown not only by the fact that the heat

effect disappears when the electrolytes are removed from the sol, but by the great variation in the shape of the curves for the different electrolytes in the region of low purity. With sodium sulfate and sodium chloride the curves have negative as well as positive branches. It seems probable that the heat effects may be attributed entirely to the shift in the equilibrium of Reaction 1 in the hydrolysis of ferric chloride. As has already been pointed out, in our present state of knowledge of ferric oxide sol we do not know very much about the constitution of the sols and the concentrations of the electrolytes present, consequently it is not yet possible to test this theory quantitatively.

Sulfuric acid as coagulant behaves very differently from the other electrolytes in that the heat of coagulation increases with increasing purity. In these experiments, on mixing the sol with the coagulant in the calorimeter, a sudden change in temperature resulted, followed by a slow rise in temperature at a rate of the order of  $0.004^\circ$  per minute continuing indefinitely. The first rapid change in temperature was measured in these experiments. These phenomena are easily understood if we consider that the solution of ferric oxide (sol or gel) in dilute acids takes place through a reversal

of the two reactions by which ferric chloride hydrolyzes. In all cases, then, we have the dispersed phase in equilibrium with the intermediate product according to Equation 2, and the latter in equilibrium with ferric ion according to Equation 1. Addition of sulfuric acid by increasing the hydrogen-ion concentration forces the equilibrium of Reaction 1 to the left, decreasing the concentration of the intermediate product, and this in turn causes more of the ferric oxide to pass into solution according to Equation 2.

In Fig. 7 is shown the heat of coagulation of ferric oxide sols of constant purity and concentration with solutions of the six electrolytes of varying

Fig. 6.—The heat of coagulation of ferric oxide sols containing 1.0 g. equiv. of  $\text{Fe}_2\text{O}_3$  per liter with different electrolytes as a function of the purity of the sol.

concentration. The data for these curves are given in Table VII. In every case the heat effect increases rapidly at first as the concentration of the coagulant increases, but soon reaches a point beyond which the change is very small. The limiting concentration of the electrolyte in

each lies between the points marked A and B. It will be seen, therefore, that the curves do not attain their maximum until some time after the limiting concentration has been passed, and that there is no "break" in any of the curves at this point. This confirms the conclusion that the heat effects observed are due entirely to the electrolytes in the sol and

Fig. 7.—The heat of coagulation of ferric oxide sol with different electrolytes as a function of the concentration of the coagulant. The sol contained 1.3 g. equiv. of ferric oxide per liter and had a purity of 15 except where otherwise indicated. The limiting concentration of the electrolyte lies between the points marked A and B.

in the coagulant, and that the act of changing the dispersity of the ferric oxide during coagulation is not associated with any measurable heat change.

### Summary.

1. The dilution of ferric oxide hydrosols of varying purity is accompanied by measurable heat effects until the purity exceeds 21 or 22, beyond which point the heat of dilution is zero. If the heat of dilution per gram equivalent of chlorine in the sol is plotted against the chlorine content, the curve is of the same nature as that for the heat of dilution of ferric chloride solutions of varying concentration.

2. The thermal behavior of ferric chloride solutions on dilution confirms the observations of Goodwin based on conductivity to the effect that the hydrolysis of ferric chloride takes place in two steps, the first an instantaneous and the second a slow reaction.

3. The mixing of ferric chloride solutions with common electrolytes involves very significant heat changes.

4. The heats of coagulation of ferric oxide sols of varying purity with sodium oxalate, sodium sulfate, sodium chloride, potassium ferricyanide,

sodium hydroxide, and sulfuric acid have been determined. The curves showing the heat of coagulation as a function of the purity vary widely in shape with the nature of the coagulant, the heat effect being usually positive, but with sodium sulfate and sodium chloride at low purities, negative. As the purity increases the heat of coagulation becomes smaller, finally becoming negligible, except in the case of sulfuric acid. The peculiar behavior of the last electrolyte is due to solution of the ferric oxide.

5. When the heat of coagulation is plotted against the concentration of the coagulating electrolyte, smooth curves are obtained showing no "break" at the point of limiting concentration.

6. The heat effects observed on coagulating ferric oxide sols with electrolytes are to be attributed to the action of the electrolytes in the coagulants upon the electrolytes, particularly ferric chloride, present in the sol. The change in dispersity of the ferric oxide on coagulation does not involve a heat change greater than 1 to 2 calories per gram equivalent of ferric oxide.

7. In the case of ferric oxide hydrosol there exists no "heat of peptization" analogous to the heat of solution of crystalloids.

The work described in this paper has been carried out with the assistance of a fellowship established by E. I. duPont de Nemours and Company, to whom the authors wish to express their indebtedness.

## THE STRENGTHS OF COBALTAMMINE BASES AND WERNER'S THEORY OF BASES.

BY ARTHUR B. LAMB AND VICTOR YNGVE.

Received July 20, 1921.

The great strength of many cobaltamine bases has attracted the attention and evoked the surprise of investigators in this field. Cobaltic hexamine hydroxide (luteo cobaltic hydroxide), for instance, is a very soluble, deliquescent substance whose solution is caustic in its properties, absorbs carbon dioxide with avidity, and displaces both ammonia and silver oxide from their salts. Werner,<sup>1</sup> estimating the strengths of various ammine bases qualitatively from their chemical behavior and from the properties of their salts, has arranged certain of them in the order of their strengths, and indeed largely on the basis of these considerations has proposed a new theory of bases and of hydrolysis. We have therefore been interested to obtain quantitative measurements of the strengths of these bases. We have used the conductivity method for this purpose, measuring the conductivities of their dilute solutions at various concentrations and comparing the resulting molecular conductivities with the conductiv-

<sup>1</sup> Werner, "Neuere Anschauungen," 3rd edition, Braunschweig, 1913, p. 265.

ities at infinite dilution, as computed from measurements of the conductivities of salts derived from them.

Solutions of the bases were prepared by triturating their bromides with an excess of moist silver oxide, the mortar, pestle, silver oxide and water having all been carefully cooled to zero degrees. The solution was then rapidly filtered by suction into a graduated 250cc. flask, the residue washed several times with 10cc. portions of ice-cold water, and the solution made up to the mark. After thorough mixing, a portion was transferred to conductivity cells and the conductivity measured, first in an ice-bath and then in a 25° thermostat. Aliquot portions of the original solution were diluted successively and lower concentrations were then measured in the same way. The more important details of manipulation were as follows.

**Preparation of Materials.**—The water was prepared by redistillation using a little barium hydroxide and potassium permanganate. It and the solutions made from it were kept in carefully closed and steam-extracted resistance-glass bottles. Its conductivity was always measured before use.

Most of the amines were prepared according to the improved methods of Jørgensen.<sup>2</sup> The hexamine bromide was, however, made by precipitation with pure conc. hydrobromic acid of hexamine chloride prepared according to the method of Lamb and Larson.<sup>3</sup> It was then washed several times with dil. hydrobromic acid and with alcohol until all the acid was removed, and finally was dried in an air-bath at 35°. The triethylenediamine bromide was prepared from the hexamine bromide according to the method of Pfeiffer,<sup>4</sup> while the dibromo-diethylenediamine bromide, which on treatment with moist silver oxide gave diaquo-diethylenediamine cobaltic hydroxide was a commercial product.

The silver oxide was prepared by the action of a clear solution of barium hydroxide on an excess of silver nitrate in dilute solution. It was washed with a large amount of conductivity water until no test for barium ion could be obtained. It was kept under conductivity water in a closed vessel.

**The Apparatus.**—Three of the conductivity cells were flask-shaped vessels of Jena glass, provided with large strongly anchored sealed-in electrodes; one consisted of dip electrodes fitted into a wide-mouthed flask. Each was closed by a rubber stopper and was provided with a thermometer legible to 0.01°. A large ice-bath served for a 0° thermostat, and the water thermostat maintained a temperature of 24.96° constant to within 0.01°. The true temperatures were established by a calibrated thermometer whose ice-point was carefully checked. The constants of the cells were fixed by means of a solution of potassium chloride made up by weight to 0.019894 molar using the density data of Baxter,<sup>5</sup> and taking the conductivity of this solution as 0.002759 mhos at 24.96°. The constants were redetermined at the end of our measurements and found to be identical with the initial values. The slide-wire bridge could be read to one part in 5000 and was carefully calibrated under the conditions of its use. No readings were taken until the contents of the cells had reached precisely the temperature of the thermostat. Successive bridge readings were in most cases

<sup>5</sup> Baxter *et al.*, *THIS JOURNAL*, **33**, 913 (1911).

constant to within the accuracy of a setting, and the mean of several readings was recorded.

In the case of the dinitro-tetrammine salts, however, a slow decrease in conductivity was noticeable at 25°, while with the carbonato-tetrammine this change was noticeable at 0° and so rapid at 25° as to make measurements of little value. In these latter cases the measurements were made over a period of 2 or 3 hours, and extrapolated to zero time.

### The Water Correction.

The correction of our conductivity measurements for the conductivity of the water is of considerable and unusual importance. This is due to the fact that the conductivity of the water, and indeed of any carefully purified water distilled in vessels open to the air is substantially that of the carbonic acid dissolved in it.<sup>6</sup> In acid or neutral solutions the corrections on this account are of no special importance, but here this carbonic acid will neutralize an equivalent quantity of the base and, as the net effect of this is to replace a swift, hydroxyl ion for a sluggish, carbonate ion, a considerable correction, at least in dilute solutions, must be applied. Calling  $C_{H_2CO_3}$  the total concentration of the carbonic acid, this correction will be

$$\Delta = \frac{2 \lambda_{OH^-} - \lambda_{CO_3^{--}}}{1000} C_{H_2CO_3}$$

where  $\lambda_{OH^-}$  and  $\lambda_{CO_3^{--}}$  are the conductivities of the hydroxyl and carbonate ions at the temperature of the measurements.

Since the specific conductivity of a solution of carbon dioxide is proportional to the square root of the partial pressure of carbon dioxide, and since carbon dioxide is only slightly dissociated even at these concentrations, the specific conductivity must also be proportional to the square root of its total concentration. A solution whose total concentration of carbon dioxide is  $2.94 \times 10^{-5}$  mols has a specific conductivity of  $0.65 \times 10^{-6}$  mhos at 0°.<sup>7</sup> Therefore, calling  $L_0$  the specific conductivity of the water at 0°,  $C_{H_2CO_3} = L_0^2 \frac{2.94 \times 10^{-5}}{0.65 \times 10^{-6}} = 6.8 \times 10^7 L_0^2$ ; and therefore  $\Delta_0 = 8.3 \times 10^6 L_0^2$ ; and  $\Delta_{25} = 2.82 \times 10^7 L_0^2$  mhos. These corrections at 0° and 25° have been applied to the specific conductivities at concentrations down to 0.00666 *M*, and since  $L_0$  varied between 0.94 and  $1.48 \times 10^{-6}$  mhos, the correction varied between 0.73 and  $1.8 \times 10^{-5}$  at 0° and 2.5 and  $6.2 \times 10^{-5}$  mhos at 25°.

This method of correction is rigorous enough at these concentrations. At still lower concentrations the question arises whether the second hydrogen of carbonic acid is sufficiently ionized to react completely with the hydroxyl ions.

<sup>6</sup> Kendall, *THIS JOURNAL*, 39, 7 (1917).

<sup>7</sup> Kendall, *ibid.*, 38, 1494-5 (1916).

If only the first hydrogen were neutralized the decrease in the specific conductivity would be<sup>8</sup>

$\Delta_{0}^{\circ} = (\lambda_{\text{OH}^-} - \lambda_{\text{HCO}_3^-})_0 \cdot C_{\text{H}_2\text{CO}_3} = 0.080 \text{ } C_{\text{H}_2\text{CO}_3} \text{ mhos}$ ; and similarly  $\Delta_{25}^{\circ} = 0.146 \text{ } C_{\text{H}_2\text{CO}_3} \text{ mhos}$ . If the second hydrogen were then neutralized, the further decrease would be  $\Delta_{0}^{\circ} = 0.042 \text{ } C_{\text{H}_2\text{CO}_3}$  and  $\Delta_{25}^{\circ} = 0.072 \text{ } C_{\text{H}_2\text{CO}_3}$ .

The extent to which these neutralizations will occur can be computed from the ionization constants of carbonic acid and of water. The ionization constant of the first hydrogen of carbonic acid is  $K_1 = 2.24 \times 10^{-7}$  at  $0^\circ$  and  $3.5 \times 10^{-7}$  at  $25^\circ$ ;<sup>9</sup> that of the second is  $K_2 = 6 \times 10^{-11}$  at  $18^\circ$ .<sup>10</sup> It is evident that at the concentration of hydroxyl ion under consideration ( $0.0001 \text{ } M$ ) the neutralization of the first hydrogen ion may be considered as complete.

The neutralization of the second hydrogen will be determined by the equilibrium equations

$$C_{\text{H}^+} \times C_{\text{OH}^-} = S_{\text{H}_2\text{O}}, \text{ and } \frac{C_{\text{H}^+} \times C_{\text{CO}_3^{--}}}{C_{\text{HCO}_3^-}} = K_2,$$

where  $S_{\text{H}_2\text{O}}$  represents the ion product of water. Calling  $C_{\text{OH}^-}$  the initial concentration of hydroxyl ion, that is, its concentration after the complete neutralization of the first hydrogen of carbonic acid,  $x$  the number of mols of the second hydrogen neutralized, and  $y$  the number of mols of carbonate ion formed at equilibrium,  $C_{\text{H}^+} = y - x$  and  $C_{\text{OH}^-} = C_{\text{OH}^-} - x$ . Then  $(y - x)(C_{\text{OH}^-} - x) = S_{\text{H}_2\text{O}}$ ; and  $(y - x)y = K_2(C_{\text{H}_2\text{CO}_3 - x})$ .

The solution of these two equations gives a third degree equation. It is therefore much simpler to solve them by a process of approximation for each set of values of the constants, first guessing a value of  $y$ , then solving each equation for  $x$ , and finally varying  $y$  until each equation gives an identical value for  $x$ . After a few trials this solution can be made very rapidly. Values of  $y$  computed in this way for  $C_{\text{H}_2\text{CO}_3} = 1.18 \times 10^{-4} \text{ } M$ , and for a series of hydroxyl-ion concentrations at  $25^\circ$  are given in Table I. These values of  $y$  divided by  $C_{\text{H}_2\text{CO}_3}$  give the fraction of the total carbonic acid converted into the carbonate ion; that is, the fraction fully neutralized. The resulting figures are entered in the fourth column of Table I. Similar computations were made for the other concentrations

<sup>8</sup> For the conductivity of  $\text{HCO}_3^-$  see Kendall, *THIS JOURNAL*, 38, 1489 (1916).

of carbonic acid. Values for intermediate concentrations of hydroxyl ions were found by graphical interpolation.

TABLE I.  
ION CONCENTRATIONS.  
[ $\text{CH}_3\text{CO}_2 = 1.18 \times 10^{-4}$ . Temperature =  $25^\circ$ .]

Initial conc. $\text{OH}^- \times 10^3 M.$	$\text{CO}_3^{--} \times 10^3 M.$	$\text{CO}_2^{--} \text{ or } \gamma \times 10^3$	$\frac{\text{CO}_3^{--}}{\text{CH}_3\text{CO}_2}$
6.67	6.54	0.115	0.97
1.33	1.21	0.103	0.87
0.667	0.549	0.087	0.74
0.218	0.100	0.033	0.28
0.133	0.016	0.0064	0.055

It can be seen from this table that the neutralization is nearly complete at the highest concentrations, and corrections for this effect were therefore only applied at concentrations of  $0.0013 M$  and below. With water of the purity used ( $L_0 = 0.9 - 1.4 \times 10^{-6}$  mhos) the total correction for water is, however, very large at the lowest concentration, so that any correction is unsatisfactory. This is shown by the large values of the water correction expressed as percentages of the total conductivity ( $\Delta/L$ ) in the tables of data. In any attempt to secure more accurate values for low concentrations much purer water should be used.

**Correction for the Solubility of Silver Oxide.**—During trituration of the cobaltamine bromide with silver oxide, and the subsequent washing some silver must dissolve, and thus contaminate the solution of the cobaltamine hydroxide. The amount of this contamination can be determined from the known solubility of silver oxide.

The total solubility of silver hydroxide is  $2.16 \times 10^{-4}$  mols per liter at  $25^\circ$ , according to the careful and direct measurements of Noyes and Kohr.<sup>11</sup> The ion concentration of the saturated solution is  $1.23$  and  $1.39 \times 10^{-4}$  mols at  $20^\circ$  and  $25^\circ$ , respectively, according to Böttger.<sup>12</sup> Assuming that the total solubility has the same temperature coefficient as the ion concentration, it will equal  $8 \times 10^{-5}$  mols at  $0^\circ$ . The total volume of water used during trituration and washing may be taken as  $50$  cc., and

<sup>11</sup> Noyes and Kohr, *Z. physik. Chem.*, **42**, 338 (1903).

<sup>12</sup> Böttger, *Z. physik. Chem.*, **46**, 602 (1903). It should be pointed out that Böttger's values are somewhat too large for silver hydroxide and lead hydroxide, as he corrected the conductivity of their solutions by simply subtracting the conductivity of the water. This neglects the fact that the carbonic acid which is chiefly responsible for the conductivity of the water will have its first hydrogen completely neutralized, and will therefore have a higher conductivity than when slightly dissociated in the original water. The correction,  $\Delta'$ , for this effect will evidently be

$$\text{CH}_3\text{CO}_2 \frac{(\lambda_{\text{Ag}^+} + \lambda_{\text{OH}^-})}{1000} \text{ or } 0.11 \text{ CH}_3\text{CO}_2.$$
 For the water which he used  $\text{CH}_3\text{CO}_2 = 2.8 \times 10^{-5}$ , and therefore  $\Delta'_{25^\circ} = 3.1 \times 10^{-6}$  and  $\Delta'_{20^\circ} = 2.8 \times 10^{-6}$  mhos. These corrections, applied to Böttger's values for the ion concentration give, for  $25^\circ$  and  $20^\circ$ , respectively,  $1.39$  and  $1.23 \times 10^{-4} M$ .

assuming its complete saturation and the complete dissociation of the silver hydroxide, the concentration of silver ion would be  $1.6 \times 10^{-5} M$ . This amount of contamination is wholly negligible in the  $3300 \times 10^{-5} M$  solutions which were chiefly studied, and practically negligible in the few  $330 \times 10^{-5} M$  solutions. No correction has, therefore, been applied to our results for this effect.

### The Conductivity Data.

The conductivity data are collected in the following tables.  $\lambda$  and  $\alpha$  signify molecular conductivity and percentage dissociation as usual,  $L_0$ , the specific conductivity at  $0^\circ$  of the water used;  $\Delta/L$ , the percentage of the total conductivity which the water correction represents at the various concentrations, and  $R$  the molecular conductivity of the hydroxide obtained by subtracting the conductivity of the neutral salt from the observed values.

In view of Werner's conclusion<sup>13</sup> that in alkaline solutions of the amines *hydroxo* compounds are present in equilibrium with the aquo hydroxide we have computed from the observed conductivities of all the aquo hydroxides the percentage ionization of the remaining hydroxide, assuming that all of the complexly bound water has been replaced by hydroxyl groups. The results obtained are collected in the columns headed  $\alpha'_{0^\circ}$  in the above tables.

#### The Conductivities at Zero Concentration.

The conductivities at zero concentration, required to compute the degree of ionization, can, in the case of the most highly ionized bases, be computed with considerable certainty from the actually observed conductivities; but in other cases and in general, on account of the serious effect of dissolved carbonic acid on conductivity measurements of bases, it is advantageous to compute these conductivities from measurements of the conductivities of salts of these bases. This is the method we have adopted. In most cases the necessary data were found in the literature. The values adopted for the conductivities of the various anions used in these com-

<sup>13</sup> Werner, Ref. 1, p. 264.

putations,<sup>14</sup> and the resulting conductivities of the various cobaltammine ions are collected in Table XIII.

TABLE XIII.  
CONDUCTIVITIES OF THE VARIOUS COBALTAMMINE IONS.

*Hexammine Cobaltic Ion.*—Although numerous measurements of the conductivity of hexammine salts have been made by Werner and Miolati<sup>15</sup> and Werner and Herty,<sup>16</sup> the results are discordant and much lower than those obtained more recently for the chloride by Harkins, Hall and Roberts.<sup>17</sup> We have, therefore, measured the conductivity of hexammine bromide at both 0° and 25°, and the results are collected in Table II. Values for the conductivity at zero concentration have been obtained by the well-known method,<sup>18</sup> based on the Storch-Bancroft equation, of plotting  $1/\lambda$  against  $(C\lambda)^{n-1}$  and varying  $n$  until the points lie as closely as possible to a straight line. The values of the exponent and the limiting conductivities thus obtained and of the molar conductivities computed inversely from them are included in the table. The close agreement of the computed and observed conductivities indicates the probable reliability of the extrapolation. The data of Harkins, Hall and Roberts on the chloride have been computed in a similar fashion; satisfactory concordance was obtained using  $n=1.50$  and  $1.48$  at 0° and 25°, respectively; giving 165.2 and 326.7 mhos for the conductivity of the hexammine ion, as compared with the 167.8 and 327.3 mhos which we obtained above from our measurements on the bromide. We have, therefore, adopted 167 and 327 mhos for our further computations. The reliability of these values is further attested by the close agreement of the conductivities of the hydroxide computed from them with the observed conductivities (Table IV).

<sup>17</sup> Harkins, Hall and Roberts, *THIS JOURNAL*, 38, 2656 (1916).

<sup>18</sup> See Noyes and Coolidge, *Carnegie Inst.*, Pub., 63, p. 50.

*Aquo-pentammine and Diaquo-tetrammine Ions.*—The conductivities of various salts of these ions have been measured at 25° by Werner and Miolati.<sup>19</sup> These measurements have shown that the aquo-pentammine and the diaquo-tetrammine salts have conductivities 12 and 25 mhos smaller than the hexammine ion at 0.0005 *M* concentration. We have, therefore, adopted 160 and 154 at 0° and 314 and 300 mhos at 25° for these values.

*Triethylenediamine Cobaltic Ion.*—The conductivities of the chloride and nitrate of this ion have been measured at 25° by Werner and Hertz.<sup>16</sup> Their measurements, extrapolated to zero concentration in the usual way give 196 and 214 mhos, respectively, for the conductivity of the triethylenediamine ion. We have adopted the mean of these results, namely 205.5 mhos. This value is confirmed by the close agreement of the conductivities of the hydroxide computed from it with the observed conductivities. No measurements of the conductivities of these salts at zero degrees have been found in the literature; we have, therefore, adopted the value 108.6 mhos, computed from the conductivity of the hydroxide at zero concentration (423.6 mhos) found by direct extrapolation. The approximate, at least, correctness of the result is confirmed by the close agreement of the temperature coefficient, derived from it, and the known value at 25°, (0.0357) with the similar coefficients of the hexammine, aquo-pentammine and diaquo-tetrammine ions, namely 0.0384, 0.0364 and 0.0360.

*Diaquo-diethylenediamine Ion.*—No measurements of the conductivities of the salts of this ion have been made, nor are our measurements of the conductivity of the hydroxide at different concentrations sufficiently concordant to permit extrapolation. We have, therefore, merely estimated the conductivity of this ion by assuming that the replacement of 4 ammonia groups in diaquo-tetrammine will produce the same change per mol. of ammonia as when all 6 ammonia groups are replaced in the hexammine to form the triethylenediamine ion. On this basis the conductivity becomes 115 at 0° and 219 mhos at 25°.

*Carbonato-tetrammine Cobaltic Ion.*—The conductivity of this ion at 25° was determined by extrapolation, taking  $n=1.33$ , of the conductivity data on the nitrate obtained by Werner and Miolati.<sup>20</sup> The value thus obtained, 33.8 mhos, is only a few per cent. less than the corresponding value for the closely related 1,2-dinitro-tetrammine ion at the same temperature. We have assumed that the values at zero degrees will bear the same proportionate relation. This gives the conductivity of the carbonato ion as 16.8 mhos.

*1,2- and 1,6-Dinitro-tetrammine Ions.*—The conductivities of these ions

<sup>19</sup> Werner and Miolati, *Z. physik. Chem.*, 12, 42 (1893); 14, 520 (1894); and 21, 237 (1896).

<sup>20</sup> Werner and Miolati, *Z. physik. Chem.*, 21, 234 (1896).

have been obtained by extrapolation of the measurements of Harkins, Hall and Roberts<sup>17</sup> on the nitrate and chloride. The exponent  $n$  was found to be 1.4 for the 1,2-dinitro nitrate and 1.5 for the 1,6-dinitro chloride, giving 18.1 and 17.9 at 0°, and 36.3 and 36.1 mhos at 25° for the 1,2- and 1,6-dinitro ions, respectively.

*Dinitro-aquo-triammine Ion.*—The conductivity of this ion at 25° has been computed by extrapolation of the measurements of Werner and Miolati<sup>21</sup> on the chloride, taking  $n=1.40$ , as 59.6 mhos. The value at 0° was found, as in the case of the carbonato, by comparison with the 1,2-dinitro ion, giving the value 29.5 mhos.

### The Degrees of Ionization.

The degrees of ionization, computed for the different concentrations in the usual way, are included in the columns headed  $\alpha_0^\circ$  or  $\alpha_{25}^\circ$  of the above tables (II–XII). To facilitate comparison the values for 0.00133  $M$  have been collected in the following table (XIV). This concentration rather than the most dilute has been selected because it is not so subject to the uncertainties involved in the water correction.

TABLE XIV.

THE PERCENTAGE IONIZATION OF THE COBALTAMMINE BASES AT 0° AND 0.00133  $M$ .

Base.	$\alpha$ %.	$\alpha'$ %.
$[\text{Co}(\text{NH}_3)_6]^{+++}$	89.5	
$[\text{Co}(\text{NH}_3)_5\text{H}_2\text{O}]^{+++}$	53.5	82.9
$[\text{Co}(\text{NH}_3)_4(\text{H}_2\text{O})_2]^{+++}$	24.6	74.0
$[\text{Co}(\text{en})_3]^{+++}$	88.6	
$[\text{Co}(\text{en})_2(\text{H}_2\text{O})_2]^{+++}$	27.3	81.8
$[\text{Co}(\text{NH}_3)_5\text{CO}_3]^+$	97.6	
1,2- $[\text{Co}(\text{NH}_3)_4(\text{NO}_2)_2]^+$	81.2	
1,6- $[\text{Co}(\text{NH}_3)_4(\text{NO}_2)_2]^+$	95.0	
$[\text{Co}(\text{NH}_3)_5(\text{H}_2\text{O})(\text{NO}_2)_2]^+$	36.0	

These results bring out clearly the following facts.

(1) These bases are very strong. The univalent bases, carbonato-1,2- and 1,6-dinitro hydroxide, are quite as highly dissociated as the alkali hydroxides, while the hexammine and triethylenediamine hydroxides have no parallels among the simple tri-acid inorganic bases as regards solubility and extent of ionization.

(2) The replacement of ammonia by ethylenediamine has no noticeable effect on the extent of ionization. Thus, the hexammine and triethylenediamine, on the one hand, and the diaquo-tetrammine and the diaquo-diethylenediamine on the other, show almost identical ionization.

(3) The replacement of ammonia or ethylenediamine by water produces a marked decrease in the degree of ionization. This is apparent on com-

<sup>21</sup> Werner and Miolati, *Z. physik. Chem.*, 12, 46 (1893); and 21, 228 and 234 (1896).

paring hexamine with aquo-pentamine and diaquo-pentamine, triethylenediamine with diaquo-ethylenediamine, and the dinitro-tetramine with dinitro-aquo-triammine. The magnitude of the change is also substantially the same, per water molecule, in each case.

(4) The substitution of acido groups for ammonia or ethylenediamine has no marked effect on the ionization; the carbonato and 1,6-dinitro appear slightly more, the 1,2-dinitro slightly less ionized than the original unsubstituted ammine. It certainly does not produce the weak base which might perhaps be expected from the usual conceptions of organic chemistry. But it must be remembered that the mere decrease in valence, such as any complexly bound acido group would produce, would tend to favor the ionization of the hydroxyl group attached by a polar valence. What little effect there is on the ionization, if it is real, would indicate that the weakest acido group ( $\text{CO}_3$ ) gave the strongest base, as would be expected. This flatly contradicts Werner's qualitative conclusions and seriously invalidates his discussion of the theory of bases.

(5) The ionization of the 1,2-dinitro- is decidedly less than that of the 1,6-dinitro-tetrammine hydroxide. This agrees with Werner's qualitative estimate.<sup>22</sup>

(6) The values of  $\alpha'_0$  are in all cases possible; that is, the assumption that *all* the complexly bound water is replaced by hydroxyl groups does not lead to values of  $\alpha'_0$  greater than 100, though, of course, this does not *prove* that any such replacement has indeed taken place.

### The Relative Ionization of the Successive Hydroxyl Groups of Hexamine Cobaltic Hydroxide.

It appeared of interest to ascertain whether there is any marked difference in the degrees of ionization of the successive hydroxyl groups of the hexamine cobaltic hydroxide. This was tested not very conclusively by tritulating, in one case, one-third of the requisite quantity of the hexamine bromide with silver oxide as above described, and adding the resulting solution to a solution of the remaining two-thirds; in another case, the proportions were reversed. From the observed molecular conductivity  $2/3$  or  $1/3$  of the conductivity of the hexamine bromide was subtracted, the remainder, given in the columns headed *R*, presumably representing the conductivity of the hydroxide. These values divided by the conductivity of the uni- or di-hydroxide at infinite dilution give the percentage ionization ( $\alpha$ ). These results are collected in Table III, above. They indicate no marked difference for the three hydroxyl groups.

### Werner's Theory of Bases.

As mentioned at the beginning of this article Werner has proposed a

<sup>22</sup> Werner, Ref. 1, p. 265.

theory of bases and of hydrolysis founded largely on considerations connected with the cobaltammine hydroxides. This theory has apparently found such scant acceptance that only a brief discussion of it, and of the bearing of our observations upon it is required. It had its origin in the discovery by Pfeiffer among the amines of chromium, and later by Werner among the amines of cobalt and other metals, of the *hydroxo-ammine* salts. These substances, formed by salting out ammoniacal solutions of certain amines, appear to contain a complexly bound hydroxyl group. Dissolved in strong acids they give solutions from which ordinary aquo salts can be isolated, while with carbon dioxide they yield carbonato salts. On this specific, and on other general evidence, Werner concludes that all bases may be divided into two classes, "anhydro" and "aquo" bases. Ordinary metallic hydroxides, such as sodium, calcium, and aluminum hydroxides, ammonia and the hydroxo-ammines are anhydro bases; while aqueous solutions of these substances contain aquo bases, in equilibrium with the anhydro bases. Only the aquo bases are ionized. Finally, neutralization, according to Werner, is not the simple union of a hydrogen ion with an hydroxyl ion, but the addition of hydrogen ion to the hydroxo group of the anhydro base.

Examined carefully there appear to be two separate and novel hypotheses in this theory. The first is that the hydroxyl group in the free base is complexly bound and must be replaced by a water (or solvate) molecule before ionization can occur. The view that ionization is due to the combination of the solvent with the solute or to the loosening of the bonds of the solute by the residual valences of the solvent, as it is variously expressed, is an old, widespread and multiform theory. Werner's modification simply is that a stoichiometric relation always exists, one molecule of water actually replacing the hydroxyl group. The water then becomes complexly bound, while the hydroxyl group is now held only by polar valences and will therefore dissociate.

Now while this precise replacement of the *acido* group by the water molecule does indeed occur in the slow ionization of chloro-pentammine cobalt chloride and similar compounds, and presumably also occurs in the ionization of hydroxo compounds, and while it might also occur with a metallic hydroxide which forms a hydrate containing precisely one molecule of water for each hydroxyl group, it is a gratuitous and arbitrary assumption not only in the case of amines such as the hexamine, the dinitro-tetrammine, etc., for which no hydroxo base and no aquo compounds corresponding to the hydroxo base have been found, but also in the case of metallic hydroxides which either do not form hydrates at all or form them containing more than one molecule of water per hydroxyl group. Thus, for instance, in the case of the hexamine base Werner would have to assume the existence of the particular ion,

$[\text{Co}(\text{NH}_3)_6(\text{H}_2\text{O})_3]^{+++}$ , for which there is to our knowledge no evidence whatever.<sup>23</sup> A more probable view would be that acido groups, including the hydroxyl group, may or may not be held complexly, that is, by non-polar bonds. If held complexly, they will not be ionized until displaced by a solvate or other neutral molecule. If not held complexly, that is, if held by electrostatic or polar valence, they will ionize at once up to an equilibrium condition, when dissolved in a suitable solvent. The ionization in each case is presumably brought about by the chemical interaction of the solute and solvent, but how definite the compositions of the resulting compounds or solvated ions are is an open question. Presumably there is a quite definite and fixed orientation of at least a few molecules of the solvent about each ion.

The second novel feature of this theory is that neutralization occurs, not by the direct combination of hydrogen ions with hydroxyl ions, but by the addition of a hydrogen ion to the complexly bound hydroxyl group of the anhydro base. That is, instead of imagining that water is first formed, the equilibrium between aquo and anhydro bases upset and hydroxo thus converted into aquo base, Werner prefers to imagine substantially the reverse procedure. The hydrogen ion, adding to the hydroxo-ammine ion, forms the aquo ion directly; this causes the re-formation of more hydroxo-ammine ion from the aquo ion with the liberation of water and the binding of the hydroxyl ion. There is no direct evidence in support of this inverted picture. It must lead to the same equilibrium conditions as the usual interpretation, and it seems unlikely that hydrogen ion would add rapidly to an hydroxo group, but not at all to an hydroxyl ion bearing an opposite electric charge.

The only evidence which Werner presents in support of this radical proposal is that hydroxo-nitro-tetrammine and hydroxo-dinitro-tetrammine react more strongly basic in solution than do the corresponding hydroxo-pentammine and hydroxo-aquo-tetrammine salts, which is the opposite to what would be expected from the usual point of view. This could, however, be predicted from his theory because, he alleges somewhat darkly, the acido group would increase the affinity of the complex hydroxyl group for the hydrogen ion.

Our measurements do show that dinitro-tetrammine is indeed stronger than diaquo-tetrammine hydroxide. But, in the first place, as indicated above, these comparisons between bases of different valences, or acidities, to use the older term, are not justifiable, for it is recognized that, other things being equal, mono-acid bases will be stronger than di-acid bases and very much stronger than tri-acid bases. In the second place, these comparisons are between nitro and aquo groups; if similar comparisons

<sup>23</sup> The nearest approach to such evidence is that hydrates of hexamine chloride containing 3 molecules of water have been prepared.

are made between nitro and ammonia or ethylenediamine groups the result is wholly different. In spite of the handicap of greater acidity (valence) there is no significant difference in their strengths; dinitro-tetrammine, hexammine, and triethylenediamine hydroxides exhibit practically the same ionization. What little difference there is accords with the usual interpretation; thus, as pointed out above, carbonato-tetrammine hydroxide is a stronger base than the stereochemically similar 1,2-dinitro-tetrammine hydroxide. Finally, it should be pointed out in this connection that the marked decrease in the strength of the bases produced by the replacement of ammonia and ethylenediamine by water, the outstanding result of our measurements, is also in accord with the usual views.

Summarizing regarding this theory we would say that, while it may well be true that any complexly bound hydroxyl group, or acido group, must first be replaced by a water molecule before ionization can occur, it is improbable that this is a necessary or sufficient mechanism for all ionization; nor can the idea that neutralization takes place exclusively by addition of the hydrogen ion to a hydroxo group be seriously entertained.

### Summary.

(1) The strengths of 9 cobaltammine bases have been determined by measuring their conductivities over a range of concentrations in dilute solutions and comparing these with the conductivities at zero concentration, as computed from measurements of the conductivities of salts derived from these bases.

(2) The determinations have shown (*a*) that these bases are very strong, certain of them are as highly ionized as the alkali hydroxides; (*b*) that the replacement of ammonia by ethylenediamine has no noticeable effect; (*c*) that the replacement by water molecules produces a marked and progressive decrease in the strength; (*d*) that the substitution of acido groups has no marked effect on the strength, the electrostatic effect of a decrease in valence perhaps offsetting the chemical effect of the acid radical; the stronger acid radical produced the weaker base; (*e*) that there is no marked difference in the ionization of the successive hydroxyl groups in hexammine cobalt hydroxide.

(3) The improbability of the distinctive features of Werner's theory of bases has been brought out, and a more probable interpretation suggested.

(4) Equations giving the important correction of the conductivity of solutions of bases for the conductivity of the carbon dioxide dissolved in the water have been derived and applied.

[CONTRIBUTION FROM THE DEPARTMENT OF CHEMISTRY, UNIVERSITY OF QUEENSLAND.]

## SUBSALTS OF BISMUTH.

BY HENRY GEORGE DENHAM.

Received July 22, 1921.

The successful preparation of various subsalts of lead by the action of the vapor of methyl iodide upon lead suboxide<sup>1</sup> has suggested that this method might also lead to definite results, if applied to the suboxides of other elements, *e. g.*, bismuth.<sup>2</sup> Moreover, it has already been established by the author<sup>3</sup> that salts of bismuth, of a lower stage of oxidation than the trivalent, can exist in aqueous solution.

## Preparation of Bismuth Suboxide.

Bismuth suboxide ( $\text{BiO}$ ) has been described by various workers<sup>4</sup> but it was Tanatar who first brought forward definite evidence of the chemical identity of this substance, his work being subsequently confirmed by Herz and Guthmann.<sup>5</sup> In the following work a slight modification of Tanatar's method was introduced.

The basic oxalate of bismuth, prepared according to Tanatar's method,<sup>2</sup> was decomposed in the apparatus already used by the author for the preparation of lead suboxide and subsalts.<sup>3</sup> With the aid of a 3-fall Sprengel pump for removing the gases formed during the decomposition, about 2 g. of oxalate could be converted into the suboxide in 6 to 8 hours at 250–260°. The suboxide retained small quantities of carbon dioxide very tenaciously, while at very low pressures the suboxide shows a tendency to lose oxygen. This is borne out in the following experiments.

Temperature, ° C.....	260	270	265	260	265	265
Duration of the decomp., hours..	8	10	10	18	36	48
Bi, %.....	90.7	91.7	91.8	93.1	95.3	95.5

Bi in  $\text{BiO}$ , calc. = 92.8%.

In making the suboxide as a preliminary step in the preparation of bismuth subsalts, the decomposition was never allowed to proceed longer than 8 hours, nor was the pressure allowed to fall sufficiently low to cause the removal of oxygen. The traces of carbon dioxide left behind in the suboxide were found to be completely eliminated during the subsequent treatment with the vapor of methyl iodide.

It is noteworthy that all samples prepared in this way were spontaneously oxidized on exposure to the air except those which approached pure bismuth in composition.<sup>2,3</sup>

## Preparation of Bismuth Subsals.

About 2 g. of the basic oxalate was mixed with about 4 times its weight of silica or of powdered glass, not too fine in grain. This was necessary

<sup>1</sup> *J. Chem. Soc.*, 111, 29 (1917); 113, 249 (1918); 115, 109 (1919).<sup>2</sup> Tanatar, *Z. anorg. Chem.*, 27, 437 (1901).<sup>3</sup> Denham, *J. Chem. Soc.*, 93, 835 (1908).<sup>4</sup> Schneider, *Pogg. Ann.*, 96, 130 (1855). Heinz, *ibid.*, 63, 55 (1844).Weber, *ibid.*, 107, 596 (1859). Berthelot, *J. Pharm.*, 14, 616 (1829).<sup>5</sup> Herz and Guthmann, *Z. anorg. Chem.*, 53, 64 (1907).

to prevent caking, and not to keep down the temperature of the reaction as in the case of lead subiodide already described.<sup>1</sup> The apparatus used in the preparation of the subsalts of lead was again adopted without alteration, nor did any material change in the method of procedure prove necessary. After the formation of an approximately pure suboxide, about 10 cc. of pure methyl iodide was introduced into the distillation vessel, and the distillation begun at a temperature of 260–262°. Extreme difficulty was experienced in bringing the reaction between methyl iodide and the suboxide to completion. Generally, after an hour's distillation the evolution of gas entirely ceased. This should indicate that the reaction is at an end, but examination of the cooled reaction vessel showed that in nearly all cases the reaction was incomplete at this stage, the product being dark red and obviously heterogeneous. A further distillation at the original temperature gave a renewed evolution of gas, this often lasting another hour. In order to take advantage of this renewed reactivity conferred upon the reaction mixture by cooling, the distillation was carried out in two stages. Five cc. of methyl iodide was distilled through the suboxide at 260–262°, the duration of the distillation being about an hour. The reaction vessel was then cooled to room temperature, and then slowly raised again to the original temperature of distillation. An additional 5 cc. was then distilled through the reaction mixture. In some cases it was necessary to subject the reaction mixture to a yet further distillation. As it had already been established that at temperatures above 262° methyl iodide oxidizes lead subiodide<sup>1</sup> to the normal iodide, no distillation tests were carried out above this temperature. At the completion of the distillation, the distillate was cooled by liquid ammonia, the apparatus partly evacuated, the vessel containing the distillate sealed off, and the apparatus completely evacuated by means of the Sprengel pump.

**Products of the Reaction.**—As a result of the distillation the following products were isolated. (1) The reaction vessel contained roughly 2 g. of a non-volatile, brick-red powder which appeared perfectly homogeneous under the microscope. (2) Just outside the oven there appeared bright red crystals of considerable volatility. (3) The distillate was yellow whereas in the corresponding case of lead subiodide it was colorless. On admitting air into the distillate a pale yellow solid separated, the methyl iodide at the same time decolorizing.

**The Product in the Reaction Vessel.**—This non-volatile, brick-red substance was found to be perfectly stable in dry air. Analysis of this compound gave the following results.

These results agree closely with the calculated percentages for the basic subiodide,  $2\text{BiI}_2 \cdot 3\text{BiO}$ . It is of interest at this stage to note that the distillation of methyl iodide over bismuth trioxide under similar conditions leads to the formation of bismuth oxyiodide, a reddish compound, the

	Bi. %.	I. %.	O (by difference). %.
	64.9	31.3	3.8
	64.8	31.7	3.5
	65.2	31.7	3.1
	64.8	31.9	3.3
	65.0	31.5	3.5
Mean	64.9	31.6	3.5
Calc.	64.9	31.8	3.3

analysis of which indicates the formula  $\text{BiOI}$  or  $\text{BiI}_3\cdot\text{Bi}_2\text{O}_3$ . The percentage of bismuth in 2 samples of this oxyiodide was found to be 58.96 and 59.00 (calc. 59.28).

Bismuth sub-oxyiodide is non-volatile even at  $300^\circ$ . On being heated in the absence of air to a temperature of  $350^\circ$  and above, the reddish subsalt becomes dark and patchy, and does not regain its former homogeneity on cooling. Presumably, decomposition into metal and a basic tri-iodide has occurred. A saturated aqueous solution of this sub-oxyiodide gives, after filtration, a barely perceptible darkening on treatment with hydrogen sulfide, while a solution of silver nitrate produces a barely detectable opalescence. Sulfuric, acetic and hydrochloric acids, as well as sodium hydroxide, cause decomposition into metal and a more soluble trivalent bismuth salt. It is insoluble in alcohol and in an aqueous solution of potassium iodide. It reduces an acid solution of potassium permanganate.

As a further criterion of the chemical individuality of this subsalt, the conductivity of various samples was compared with that of the basic iodide,  $\text{BiOI}$ , formed as above from bismuth oxide, the method of procedure in determining the solubility being precisely as described in a previous paper.<sup>6</sup> The measured resistance of the oxyiodide was found to be by two tests  $745 \pm 15$  ohms; that of the sub-oxyiodide was  $9000 \pm 900$  ohms.

**The Red Volatile Product.**—Mention has been made of the fact that a red, volatile, crystalline product separated in the tubes leading from the oven. This occurred in all cases. In order to test whether this substance was produced during the distillation by a side reaction, or was the product of the decomposition of the sub-oxyiodide, a sample of the latter compound was sealed to the pump, evacuated, and heated to  $262^\circ$ . After prolonged evacuation no sign of such a volatile substance outside the oven could be detected.

During each distillation small quantities of these bright red crystals, rarely more than 0.04 g., were formed. In order to determine the percentage of bismuth which they contained, the crystals were weighed into a platinum crucible, covered with dil. nitric acid, evaporated to dryness and gently ignited. Control experiments performed with a similar weight of the trioxide of bismuth showed that the analysis by this method could

<sup>6</sup> *J. Chem. Soc.*, 111, 29 (1917).

be relied on to yield a result correct to 0.1 mg. The balance used was sensitive to 0.05 mg. The iodine was determined by treating the crystals with an aqueous solution of silver nitrate to which dil. nitric acid was afterwards added to dissolve out traces of metallic bismuth. The precipitate of silver iodide was gathered on a Gooch crucible, according to the ordinary procedure. Three analyses of bismuth were carried out and two of iodine showing 44.9, 44.8 and 45.0 (av. 44.9) % of bismuth, and 55.2 and 54.9 (av. 55.05) % of iodine, as compared with 45.04 % of bismuth and 54.96 % of iodine calculated. The results agree very closely with the percentage composition of  $\text{BiI}_2$ . Such a compound has been described by Bertholet,<sup>7</sup> who obtained it in the form of metallic, leafy crystals by melting together iodine and bismuth.<sup>8</sup> The following description throws doubt upon the chemical identity of the product obtained in these earlier experiments. The crystals of bismuth subiodide obtained by the distillation of methyl iodide over bismuth suboxide are of a bright red color, and form long needles in the orthorhombic system. On treatment with water freed from dissolved oxygen a solution was obtained which gave much stronger reactions for bismuth and iodine than given by the suboxyiodide. In the absence of oxygen the subiodide dissolves without decomposition in ethyl alcohol and in methyl iodide, forming in both cases a clear yellow liquid. It is also freely soluble in an aqueous solution of potassium iodide, producing a solution closely resembling in appearance that of potassium dichromate. Bismuth subiodide rapidly reduces an aqueous solution of iodine and an acid solution of permanganate. On heating above 400° it decomposes into bismuth tri-iodide which volatilizes, leaving a residue of bismuth.

**The Pale Yellow Product from the Distillate.**—The distillate of methyl iodide was yellow in color. On cooling this with liquid ammonia, a white, curdy precipitate separated, which redissolved immediately on warming to room temperature. In the absence of air this distillate remained yellow and homogeneous for 9 days at a temperature between 15° and 20°, but shortly after the admission of air or of oxygen, about 0.05 g. of a white solid separated in each experiment. In the course of a few days the color of this solid turned to a distinct yellow while the supernatant liquid lost its color. Analysis of this solid showed that in all cases bismuth, iodine and carbon were present, while its separation only in the presence of oxygen is sufficient confirmation of the presence of this element. Analyses of the bismuth and iodine content showed that the composition of the solid varies from experiment to experiment, the last two samples showing 90.3 and 85.2% of bismuth, and 5.8 and 9.4 % of iodine, respectively; and in some of the analyses the percentage of bismuth fell as low as 71% and

<sup>7</sup> Bertholet, Ref. 4.

<sup>8</sup> See also Weber, Ref. 4.

the iodine was as high as 22 %. The yellow product was insoluble in alcohol and proved to be a strong reducing agent, for its addition to an aqueous solution of silver nitrate caused the precipitation of a mixture of silver and silver iodide. The above facts appear to be best interpreted on the assumptions that, (1) the distillate contains a varying quantity of the volatile bismuth subiodide carried over in the vapor of methyl iodide; (2) there is also present in the distillate bismuth dimethyl ( $\text{Bi}(\text{CH}_3)_2$ ) for it is extremely improbable that a volatile compound could exist wherein the ratio of bismuth to iodine is as high as 90.3:5.8 or even 85.2:9.4.

The first of these hypotheses was tested by inserting a short fractionating column between the reaction vessel and the condenser. The result was to make a marked reduction in the amount of iodine present in the solid, while the color of the solid became nearly white. It was also shown that bismuth subiodide, dissolved in methyl iodide, does slowly oxidize in air (oxygen) with the production of a yellow powder.

Owing to the small amount of material available it was impossible to test the second hypothesis conclusively. The percentage composition rules out the possibility that the whole of the bismuth came over in combination with iodine, and the most reasonable supposition appears to be that it distilled over in the form of a methyl compound. Bismuth trimethyl is well known, but it has been shown by Marquardt<sup>9</sup> that the halogens do not oxidize this compound, but replace the methyl groups. Hence the oxidation of bismuth trimethyl by oxygen could not yield a product possessing reducing properties sufficient to account for the reduction of silver nitrate to metallic silver.

Since the author has shown that the oxidation product of bismuth subiodide, formed by the action of oxygen upon a solution of the subiodide in methyl iodide, does not possess such reducing power, the most tenable hypothesis is that bismuth is carried over in the distillate as bismuth dimethyl, which on oxidation passes into such a compound as dimethoxy bismuth,  $\text{Bi}(\text{OCH}_3)_2$ .

### Summary.

1. Bismuth sub-oxyiodide,  $2\text{BiI}_2 \cdot 3\text{BiO}$ , a brick-red powder of considerable stability, has been isolated.
2. Bismuth subiodide,  $\text{BiI}_2$ , has been prepared as a red, volatile crystalline substance, belonging to the orthorhombic system.
3. Evidence has been adduced that bismuth dimethyl,  $\text{Bi}(\text{CH}_3)_2$ , has been isolated. It oxidizes readily and produces a strongly reducing substance, possibly dimethoxy bismuth,  $\text{Bi}(\text{OCH}_3)_2$ .

## THE REDUCTION OF SOLUTIONS OF FERRIC SALTS WITH MERCURY.

By LEROY W. MCCAY AND WILLIAM T. ANDERSON, JR.

Received July 22, 1921.

### Historical.

K. Schaffhäutl<sup>1</sup> seems to have first recognized the fact that mercury reduces aqueous solutions of ferric chloride, or more rapidly after the addition of hydrochloric acid, with the formation of ferrous chloride and mercurous chloride. The same observation was made many years later by Carnegie;<sup>2</sup> and in 1911 Borar<sup>3</sup> showed the reaction to be so complete that mercury can be used as a reducing agent for ferric compounds in the quantitative estimation of iron.

This method of reducing ferric chloride solutions was observed independently by one of us (M) over a year ago and supposed at the time to be new, for there is not even a reference to it either in the works of Rose and Fresenius, or in the most recent editions of the treatises on volumetric analysis by Classen<sup>4</sup> and by Beckurts.<sup>5</sup>

Our experience has been that the conclusion arrived at by Borar is correct. His description of the method, however, is unsatisfactorily brief, and since but two quantitative results are given to substantiate his claim, it seemed well to make a detailed study of the reaction, especially as regards its application to the preparation of ferrous chloride solutions prior to titrating them with potassium permanganate or dichromate.

### Theoretical.

When a solution of ferric chloride, containing or not containing free hydrochloric acid, is shaken violently for a few minutes in the presence of metallic mercury, the iron is completely reduced to the ferrous condition, an equivalent amount of mercurous chloride being formed.

The filtrate from the slate-colored mass of finely divided mercury and mercurous chloride gives upon the addition to it of potassium thiocyanate no red color. A solution of ferric sulfate, containing or not containing

<sup>5</sup> Beckurts, "Die Methoden der Massanalyse," Vieweg u. Sohn, Braunschweig, 1913.

free sulfuric acid, is but partially reduced (at 20°) when similarly treated, a state of equilibrium being reached.

However, on adding a little hydrochloric acid and again shaking, a complete reduction to the ferrous state is effected. Indeed, a solution of ferric sulfate containing no free hydrochloric acid, but sodium or potassium chloride instead is also completely reduced when shaken violently in the presence of mercury. An amount of sodium chloride equivalent to the quantity of mercurous sulfate formed according to the above equation is sufficient for this purpose.

Although mercurous chloride is an exceedingly insoluble salt,<sup>6</sup> the liquid after reduction always contains a minute amount of mercury in solution.<sup>7</sup>

Its presence is indicated by the black precipitate which appears when a current of hydrogen sulfide is passed into the filtrate. The quantity is so small that thus far we have made no attempt to determine it quantitatively.

In reducing with mercury hydrochloric acid solutions of ferric chloride, containing or not containing sulfuric acid, no especial attention need be paid to the amounts of free acids present, providing of course their concentrations are kept within reasonable limits. If, however, as will be shown later, the Zimmermann-Reinhardt modification of the permanganate method be employed for titrating the ferrous chloride, the 100 to 150 cc. of the solution to be reduced should contain not over 10 cc. of hydrochloric acid, sp. gr. 1.18-1.19.

The exceedingly small amounts of mercurous chloride and sulfate formed when dil. hydrochloric and sulfuric acids are shaken with mercury for 4 or 5 minutes are due most probably to the presence of atmospheric oxygen.<sup>8</sup>

The reactions proceed slowly, but in the course of several days, or a week, the quantities of mercurous salts formed are relatively large. Their presence has, of course, no bearing on the reduction of the ferric solutions.

### Experimental.

The reductions were made in a long, narrow glass bottle of about 800 cc. capacity, provided with a well-ground neck, and tightly fitting well-ground glass stopper. On shaking such a bottle the mercury present is more readily broken up into tiny globules and the reduction of the ferric

<sup>8</sup> Berthelot, *Ann. chim. phys.*, [5] 23, 100 (1881). See also Bailey, *J. Chem. Soc.*, 53, 760 (1888).

salt accelerated. About 20 cc. of redistilled mercury<sup>9</sup> (270 g.) was placed in the bottle, the ferric chloride solution (100 to 150 cc.) containing 10 cc. of hydrochloric acid, sp. gr. 1.18-1.19, added, the stopper introduced, and the whole shaken vigorously for from 4 to 5 minutes. We have found that when 0.1400-0.1800 g. of iron is present the reduction is always complete at the end of 5 minutes. The stopper was then removed, washed off into a beaker, the solution along with any suspended mercurous chloride decanted into the same beaker, and the liquid then filtered by suction. The mixture of mercury and mercurous chloride remaining in the bottle was washed by decantation 5 times, 20 cc. of water being employed for each washing. All separate wash waters were poured first into the beaker and then through the filter, the final volume of the liquid amounting to about 300 cc. Since the mercury in the bottle after a reduction, although mixed with mercurous chloride, is still as active as when first used, we simply stopper the bottle and place it aside so that it may be ready at any moment for further reductions. The mixture of mercurous chloride and finely divided mercury remaining in the beaker and on the filter paper may be preserved and, when a sufficient amount has collected, the mercury may be recovered by covering the mass with a strong solution of stannous chloride, adding hydrochloric acid, and heating for several hours.

In a number of solutions so reduced the iron was determined by the Zimmermann-Reinhardt,<sup>10</sup> as well as by the Penny<sup>10</sup> method.

1. The solution consisted of pure crystalline ferric ammonium sulfate, a liter at 20° containing 14.0765 g. of the salt and 100 cc. of hydrochloric acid, sp. gr. 1.18. The strength of the solution was unknown to the experimenter (A.). He used 100 cc. for each determination. Using the Zimmerman-Reinhardt method and 0.1 *N* potassium permanganate he obtained 0.1627, 0.1625, 0.1630, and 0.1627 g. of iron; with the Penny method and 0.1 *N* potassium dichromate he obtained 0.1624, 0.1627, 0.1629, 0.1631, 0.1627, and 0.1627 g. of iron. The average for the former method is 0.1627; for the latter, 0.1627 g. His results agree well with the amount which theory demands, 0.1630 g. The average time necessary to make a determination according to Zimmermann-Reinhardt was 21, according to Penny, 29 minutes. The difference, 8 minutes, is the time required to obtain the end-point on the porcelain spot plate. The average time for filtering and washing combined was 11 minutes. Different analysts require, of course, different intervals of time in which to perform the same operations, still the above will give a fair idea as to the amount of time involved in making a determination, after the substance containing the iron is once in solution.

2. A specimen of finely ground hematite was used. The percentage of iron present was unknown to the experimenter (A.). The ore was dissolved in conc. hydrochloric acid, water added and the small amount of insoluble matter removed by filtration.

The latter was fused with a little sodium carbonate, the melt dissolved in dil.

<sup>9</sup> G. A. Hulett, *Phys. Rev.*, 21, 6 (1905).

<sup>10</sup> Treadwell-Hall, "Quantitative Analysis," John Wiley and Sons, New York, 1915, pp. 609 and 641.

hydrochloric acid and the solution added to the main portion. The reduction was carried out as already described. By the Z.-R. method 62.92 and 62.90% of iron were found; by the Penny method 62.94 and 62.94%. The ore had been carefully examined by reducing its sulfuric acid solution with zinc in a Jones reductor, and titrating with potassium permanganate. By this method 62.85% (av.) of iron was found, as compared with 62.92% (av.) found by reduction with mercury in hydrochloric acid solution.

3. Magnetite (Sample 29) from the Bureau of Standards was used. The ore was first dried at 100° to constant weight, and then dissolved in conc. hydrochloric acid exactly as described under (2). In this case also the iron content was unknown to the experimenter (A.). The Z.-R. method gave 55.67, 55.68 and 55.71% of iron; and the Penny method, 55.72, 55.67, 55.64%; average 55.68%. According to the Bureau of Standards the ore contains 55.75% of iron.<sup>11</sup>

Since titanous acid is *not* reduced by mercury the method may be employed in determining iron in titaniferous ores and minerals. That the presence of titanous acid in the solution introduces no error will be evident from the following results.

TABLE I.  
DETERMINATION OF IRON IN THE PRESENCE OF TITANIC ACID.

Fe taken, <sup>a</sup> G.	TiO <sub>2</sub> taken. G.	Fe found. G.
0.1416	0.0903	0.1413
0.1879	0.0087	0.1880
0.1879	0.0113	0.1877
0.1517	0.0158	0.1517

<sup>a</sup> Calculated from amount of crystallized ferric ammonium sulfate weighed out in each case.

The titrations were carried out according to the Z.-R. method.

To get some idea as to the amount of ferric iron reduced by mercury when the solution is a sulfuric acid one, we prepared 500 cc. of a solution containing 8.1161 g. of crystalline ferric ammonium sulfate and 25 cc. of conc. sulfuric acid. This was poured into a dry bottle containing 20 cc. of pure mercury, the bottle was stoppered, shaken violently for 10 minutes, and the whole let stand for 30 minutes. The entire operation was carried out at 20°. Since the supernatant liquid was now perfectly clear, 50 cc. was pipetted into a beaker, the mercurous mercury in solution was precipitated with dil. hydrochloric acid as mercurous chloride, this filtered off, and the filtrate titrated with permanganate according to the Z.-R. method. The removal of the mercurous mercury is imperative, for solutions of mercurous salts reduce permanganate. The bottle and contents were shaken again at intervals, and after one hour, 50 cc. was removed and treated as before. The procedure was repeated, the intervals being lengthened each time.

<sup>11</sup> Dr. Shimer of Easton, Pa., found 55.65 % Fe.

2	1.5	0.0498	53.08
3	4	0.0499	53.22
4	30	0.0499	53.22
5	148	0.0497	52.95
6	444	0.0499	53.22
		Av.	53.15%

In the circumstances, then, the state of equilibrium was reached when somewhat over half the iron had been reduced to the ferrous condition.

When a solution of ferrous sulfate containing free sulfuric acid is shaken with mercurous sulfate and mercury a part of the ferrous salt is oxidized to the ferric salt, the following reaction taking place.

This reaction is, of course, the reverse of the above, but the time required to reach the equilibrium position is in this case considerable. Thus far we have made no attempt to determine the extent of oxidation in any specific case.

That the presence of a very small amount of sodium chloride in a solution of ferric sulfate (even when no free sulfuric acid is present) is sufficient to further a complete reduction of the iron to the ferrous condition when the solution is shaken with mercury will be evident from the following experiment.

0.5002 g. of ferrous ammonium sulfate (= 0.0712 g. of Fe) and 0.5985 g. of crystallized ferric ammonium alum (= 0.0692 g. of Fe) were dissolved in about 100 cc. water, exactly 0.0725 g. of sodium chloride (amount equivalent to the mercury oxidized) was added, the solution reduced with mercury, the mercurous chloride filtered off, the filtrate acidified strongly with sulfuric acid, diluted to 250 cc., and the iron determined with 0.1 *N* potassium dichromate solution. The iron found was 0.1405 g. compared with 0.1404 g. present.

As we have already pointed out, the reaction which takes place when a solution of ferric sulfate is shaken in the presence of mercury may be represented by  $2\text{Hg} + \text{Fe}_2(\text{SO}_4)_3 \rightleftharpoons 2\text{FeSO}_4 + \text{Hg}_2\text{SO}_4$ . Since 56 g. of iron is, according to the above equation, equivalent to 200 g. of mercurous mercury, 28 g. of iron is equivalent to 100 g. of mercury which in turn is equivalent to 29.25 g. of sodium chloride. Fifty cc. of 0.1 *N* potassium permanganate shows the presence of 0.28 g. of pure iron, and 0.3 g. sodium chloride is a little more than necessary to precipitate the mercury in the mercurous sulfate formed during the complete reduction of the 0.28 g. of iron to the ferrous state. If then we add to a sulfuric acid solution of ferric sulfate, containing not more than 0.28 g. of iron, 0.3 g. of sodium chloride dissolved in a little water, and shake the solution with mercury, we can, after filtering off the mercurous chloride, dilute the filtrate to 500 cc. and *without* adding the Z.-R. mixture proceed at once to titrate with the per-

manganate. The end-point is sharp, the pink color persisting for at least 5 minutes. The results are very satisfactory as will be evident from those given below.

A solution of crystallized ferric ammonium alum was prepared containing in 250 cc. 12.1813 g. of the salt and 5 cc. of conc. sulfuric acid. For each determination 25 cc. (=0.1410 g. of Fe) was taken, 0.3 g. of sodium chloride added, the solution diluted to 100 cc. and the reduction effected with mercury. The filtrate from the mercurous chloride was mixed with more sulfuric acid, diluted to 50° cc. and titrated at once with permanganate solution. 25 cc. = 0.1410 g. Fe. Our analyses showed 0.1411, 0.1414, 0.1408 and 0.1412 g. of iron, (av. 0.1411 g.) as compared with 0.1410 taken.

This method for reducing with mercury solutions of ferric salts is quick, accurate and very convenient. Barring the ordinary reagents and apparatus which are always at hand, only a well stoppered bottle and pure mercury are necessary. The mixture of mercury and mercurous chloride remaining in the bottle may be used over and over again, for after 33 reductions we have found it to be fully as active as was the original pure mercury.

In view of this, as well as of the fact that while zinc reduces titanous acid and mercury does not, the latter metal has an advantage over the former in preparing iron compounds for titration. Moreover, the zinc in a Jones reductor oxidizes rapidly, unless the metal be kept covered with water, and time is required to dissolve out the products of the oxidation with sulfuric acid so that the zinc will function properly. In using stannous chloride a number of details must be carefully observed, and solutions of the salt deteriorate rapidly unless preserved in a non-oxidizing atmosphere. Solutions of ferric salts, containing titanous acid, are frequently reduced at their boiling points with hydrogen sulfide or sulfur dioxide. The procedure is tedious, for to expel the excess of gas continued boiling with subsequent cooling in a current of an indifferent gas is necessary. It is evident also that if the indifferent gas contain traces of air, small amounts of ferrous salt may be reoxidized during the cooling of the solution.

Solutions of potassium ferricyanide, potassium chromate, ammonium molybdate, sodium vanadate, potassium antimoniate, etc., when acidified with hydrochloric acid and shaken with mercury are reduced. Some of these reactions are being investigated.

### Summary.

1. Solutions of ferric chloride, containing or not containing free acid, are rapidly and completely reduced when shaken in the presence of mercury. The same is true of solutions of ferric sulfate, providing a little free hydrochloric acid or alkali chloride be present. Under similar conditions titanous acid is not reduced.

2. A number of determinations of the iron in crystallized ferric ammonium alum, in hematite and in a specimen of magnetite from the Bureau

of Standards prove that this method of reduction is quick, accurate and most convenient.

3. Some of the advantages of the method over those most commonly employed have been outlined.

4. Mention is made of a number of other substances whose solutions are reduced by mercury.

## THE SEPARATION OF COLUMBIUM AND TANTALUM BY MEANS OF SELENIUM OXYCHLORIDE.<sup>1</sup>

By HENRY BALDWIN MERRILL.

Received July 22, 1921.

It was found by Lenher<sup>2</sup> that columbium oxide is soluble in a mixture of sulfuric acid and selenium oxychloride, while tantalum oxide is insoluble, or very much less soluble, in the same reagent. This appeared to afford a means of separating the two elements. The purpose of the present investigation was to work out the best experimental conditions for accomplishing the separation.

**Previous Methods.**—The separation of columbium and tantalum has hitherto been one of the most difficult tasks with which the chemist is confronted. In their chemical properties, the corresponding compounds of the two elements show hardly any points of divergence which are sharp enough to be used for methods of separation. Of the various methods which have been proposed, only one—the double fluoride method of Marignac<sup>3</sup>—merits any consideration. The Marignac method consists of the crystallization of the normal potassium fluotantalate,  $K_2TaF_7$ , under such conditions of acidity and concentration of potassium fluoride that the columbium will form the more soluble oxyfluoride,  $K_2CbOF_5$ . The chief advantage of the Marignac method is that the two double fluorides are not isomorphous, and hence no mixed crystals should be obtained. The difference in crystal form affords a convenient means of following the course of the separation. The disadvantages of the method are many and serious. The ratio of the solubility of the columbium compound to that of the tantalum is only about 10 to 1, potassium columbium oxyfluoride being soluble in 12 parts of hot water, and potassium fluotantalate requiring about 120 parts. This necessitates many recrystallizations before an approximately complete separation is accomplished, and in no case can all of either constituent be obtained in a state of purity, since some of each will inevitably remain in the various mother liquors. From the analytical standpoint, this means that the Marignac method cannot be made other than a very rough one. Its limit of error is probably at least 10%. In addition to this inherent error, the method is liable to grave inaccuracies, due to the difficulty in maintaining the concentration of hydro-

<sup>1</sup> Abstract of a portion of a thesis presented to the University of Wisconsin, in partial fulfilment of the requirements for the degree of Doctor of Philosophy, 1921. The work was financed in part by a grant from the University research fund.

<sup>2</sup> Lenher, *THIS JOURNAL*, 43, 29 (1921).

<sup>3</sup> Marignac, *Ann. chim. phys.*, [4] 3, 5, 49, 68 (1866). Simpson, *Chem. News*, 99, 243 (1909).

fluoric acid and of potassium fluoride constant within very narrow specified limits. If the acidity is too great, the columbium forms a normal fluoride; if too low, the tantalum may form an oxyfluoride; in either case, the whole basis of the separation is destroyed. If too much or too little potassium fluoride is present, double fluorides are formed in which the ratio of potassium fluoride to columbium or tantalum pentafluoride is more or less than 2 : 1. Finally, the Marignac method is extremely laborious and time-consuming, and requires the use of platinum vessels throughout.

**The Problem.**—In the ordinary course of analysis, columbium, tantalum and titanium are separated from the other elements as oxides. Titanium accompanies columbium in the Marignac separation, and no separation of columbium and titanium is known. Titanium dioxide and columbium pentoxide ( $\text{Cb}_2\text{O}_5$ ) are both soluble in selenium oxychloride and sulfuric acid. The problem, therefore, is to extract these two oxides completely from a mixture with tantalum pentoxide ( $\text{Ta}_2\text{O}_5$ ), under such conditions that the minimum amount of the last is dissolved. To ascertain these conditions, the effect of various factors upon the solubility of each oxide was first determined separately. From the data thus obtained, a tentative method of separation was formulated, and tested upon synthetic mixtures of the oxides.

**Reagents.**—The columbium and tantalum oxides employed were obtained from various commercial sources, and from stocks previously prepared in this laboratory. These oxides were further purified by the Marignac method.

Selenium oxychloride was prepared by the interaction of selenium dioxide and tetrachloride and was purified by vacuum distillation.<sup>4</sup> The purity of the other reagents employed was ascertained by the usual tests.

### Manipulation.

To determine the effect of various factors upon the solubility of each oxide, the oxide in question was boiled with the solution of selenium oxychloride and sulfuric acid in an Erlenmeyer flask, using a sand-bath. The mouth of the flask was covered with a small watch glass, the upper part of the flask acting as an air condenser, so that with proper regulation of the heat very little of the solvent was lost, and little or no hydrolysis of the oxychloride took place. The solution was filtered with suction, through an asbestos mat, in a Gooch crucible. In some cases, an excess of the oxide was employed, and the amount dissolved was determined in a known amount of the filtrate. In most instances a weighed sample of the oxide was employed, and the undissolved portion was transferred to the crucible, ignited, and weighed.

By this procedure, the effect of the following factors upon the solubility was determined: (1) composition of the reagent; (2) condition of the oxide, *i. e.*, hydration; (3) size of sample; (4) time of digestion; (5) amount of solvent employed. The temperature was in all cases the boiling point of the solvent.

<sup>4</sup> Lenher, *THIS JOURNAL*, 42, 2498 (1920).

The rate of solution of both oxides is slow, so that results obtained do not represent the true solubility, but rather the amount dissolved under definite experimental conditions in a short time (minutes or hours).

**Composition of the Reagent.**—Neither columbium oxide nor tantalum oxide is acted upon by selenium oxychloride alone. Columbium oxide is readily soluble in conc. sulfuric acid, even when the oxide is ignited. Tantalum oxide is soluble in sulfuric acid to a much less extent. The effect of adding selenium oxychloride to sulfuric acid is to decrease the solubility of both oxides. Experiments have shown that a mixture of equal parts by volume of the reagent constituents is best suited for the separation of columbium and tantalum pentoxides. When an excess of the oxide is boiled for 30 minutes with 50 cc. of this reagent, the approximate amounts of pentoxides dissolved are 0.35 g. and 0.005 g., respectively. In conc. sulfuric acid, the amounts dissolved are 0.9 g. and 0.08 g. The effect of increasing the ratio of the oxychloride to the acid beyond 1 : 1 is to decrease the solubility of columbium pentoxide much more than that of tantalum pentoxide.

Free sulfur trioxide as contrasted with sulfuric acid, has practically no solvent action upon either oxide. Solutions of fuming sulfuric acid in selenium oxychloride, such as were employed in Lenher's experiments, have about the same action as solutions of conc. sulfuric acid.

It is probable that the sulfuric acid attacks the oxide in the first instance, forming a loose addition compound which is soluble in selenium oxychloride. This is evidenced by the fact that, once the oxide has been dissolved, the solution may be diluted with selenium oxychloride to any extent without the formation of a precipitate.

**Hydration of the Oxides.**—The freshly precipitated hydrated oxides are much more readily soluble than are the ignited oxides. While the solubility decreases with increasing temperature of ignition, the solubility of hydrated tantalum peroxide is too great to permit the separation to be applied to the hydrated oxides, and good results can be obtained only when the oxides have been ignited at bright red heat.

**Effects of Size of Sample, Amount of Solvent and Time of Digestion.**—The effects of these factors are not the same upon the solubilities of both oxides. Tantalum pentoxide is so slowly soluble that equilibrium is not even approached in actual practice. Hence the amount dissolved is independent of the amount of solvent employed, and is directly proportional to the amount of solid oxide present, *i. e.*, to the surface exposed, and to the time of contact between solvent and solid. With columbium pentoxide, the process of solution is fairly rapid, so long as the amount of surface exposed is large. If the oxide is present in large excess, the amount dissolved is approximately proportional to the amount of solvent, and is independent of the amount of oxide taken and of the time, showing that equilibrium is at least approached. When, however, the amount of solid

columbium pentoxide is small, the rate of solution is very slow. If a large sample is treated with an excess of the reagent, the larger portion of the oxide is quickly dissolved, but the rate of solution becomes slower and slower as the area of contact between the phases diminishes. The solution of the last traces of columbium pentoxide takes place very slowly indeed. This means that *complete* solution of a given sample requires a considerable period of digestion, and furthermore that this period will be about the same whether the actual quantity of oxide originally taken is large or small.

Experiments have shown that an hour's boiling with the 1:1 reagent is required for the complete solution of a given sample of columbium pentoxide. So long as the solvent is present in excess, increasing the amount of solvent has little influence upon the time. Fifty cc. of solvent per 0.25 g. of columbium pentoxide has been found sufficient. The amount of tantalum pentoxide dissolved in this amount of reagent in an hour depends entirely upon the amount of this oxide which is present. It is obvious that from the analytical standpoint, the direction and magnitude of the errors are dependent upon the relative proportions of the two oxides which are present in a mixture. In all cases, there is some danger that traces of columbium pentoxide will not be dissolved. If the percentage of tantalum is low, very little tantalum pentoxide will be dissolved, and hence the results found will tend to be high for tantalum and low for columbium. If the percentage of tantalum is high, considerable amounts of tantalum pentoxide may be dissolved, in which case the results found will be low for tantalum and high for columbium. When the two oxides are present in approximately equal amounts, the two errors will be roughly compensatory.

The size of the sample employed must be kept as small as is consistent with percentage accuracy of weighing, in order to keep the amount of tantalum oxide present as small as possible. Samples of from 0.2 to 0.3 g. have been found to give the best results.

#### **Procedure for the Analysis of Mixed Oxides of Columbium and Tantalum.**

In accordance with the results of the experiments described above, the following method for the analytical separation of the two oxides is suggested.

1. The oxides are separated, together with titanium dioxide if the latter is present, from the other elements by the usual methods and the total percentage of tantalum and columbium pentoxides (plus titanium dioxide) is determined.

2. A weighed sample (0.2 to 0.3 g.) of the ignited oxides is boiled with 50 cc. of a 1:1 mixture of selenium oxychloride and conc. sulfuric acid in an Erlenmeyer flask on a sand-bath for half an hour, care being taken

that the boiling is not so vigorous that clouds of vapor are given off. The contents of the flask, after cooling, are decanted with suction through a weighed Gooch crucible. The filtrate is poured into a large volume of water, and the resulting solution is brought to a boil. A voluminous white precipitate of hydrated columbium pentoxide indicates the presence of columbium in the mixture. The residue in the flask is boiled with 20 cc. of the reagent for 15 minutes, the solution decanted through the crucible, and the filtrate poured into water. This process is repeated until the filtrate, upon hydrolysis, gives only a faint precipitate, due to traces of dissolved tantalum pentoxide. Care should be taken that as little as possible of the solid oxide is carried onto the filter in the first decantations, since this portion escapes treatment in the subsequent extractions. By this procedure, the course of the solution of the columbium oxide can be followed. Three or four treatments of the oxide with the reagent are usually enough to remove all the columbium pentoxide.

3. The undissolved tantalum pentoxide is transferred to the crucible with the jet from a wash-bottle. Complete washing of the oxide is not necessary, since all the decomposition products of the reagent are volatile. The crucible is ignited and weighed, the gain in weight representing the pentoxide. Columbium (plus titanium) is determined by difference. The titanium is best determined colorimetrically in a separate sample, and deducted from the columbium.

The method outlined above was applied to synthetic mixtures of tantalum and columbium pentoxides. In a number of experiments, the mixed oxides were fused with potassium hydrogen sulfate, and precipitated by hydrolysis, in order to simulate actual working conditions. The results obtained with these intimate mixtures were no different from those obtained with mechanical mixtures.

The maximum divergence of the results found from the amount taken is about 3% of the total amount taken, and is in the most cases much less. The errors are far smaller than those to which the Marignac method is liable. In simplicity and speed, the superiority of the separation proposed over the Marignac method is very marked. An analysis of the mixed oxides may be begun and completed in a few hours, using the

selenium oxychloride-sulfuric acid method, while days or even weeks are required by the Marignac method.

It is believed, therefore, that the method proposed for the separation of columbium and tantalum is superior to any other yet proposed.

### Procedure for the Preparation of Pure Oxides.

To prepare pure columbium pentoxide, the mixed oxides should be extracted with sufficient solvent to dissolve all of the columbium. The boiling should not be prolonged until all of the columbium is dissolved, since the object is to dissolve as little tantalum pentoxide as possible. The dissolved oxide is precipitated with water and ammonia, filtered, and ignited. Some tantalum pentoxide will inevitably be dissolved during the extraction, but by repeating the treatment upon the oxide obtained by the first extraction, very pure columbium pentoxide may be obtained, since the amount of tantalum pentoxide present during the second purification is so small that virtually no tantalum will be dissolved.

To prepare pure tantalum pentoxide, it is only necessary to extract the oxide with the reagent until all of the columbium is dissolved, sacrificing the portion of the tantalum which goes into solution. The complete removal of the columbium may be expedited by increasing the proportion of sulfuric acid in the reagent.

### Summary.

A method for the separation of columbium and tantalum, both for purposes of analysis and of purification, by means of selenium oxychloride and sulfuric acid, has been described.

This work was performed by the author while acting as research assistant to Professor Victor Lenher.

## [CONTRIBUTION FROM THE CHEMICAL LABORATORY OF THE UNIVERSITY OF WISCONSIN.] THE SEPARATION OF MOLYBDENUM AND TUNGSTEN BY MEANS OF SELENIUM OXYCHLORIDE.<sup>1</sup>

BY HENRY BALDWIN MERRILL.

Received July 22, 1921.

It was found by Lenher<sup>2</sup> that molybdenum trioxide is soluble in selenium oxychloride, while tungstic oxide is insoluble in this reagent. Since none of the methods hitherto known for the separation of molybdenum and tungsten is entirely satisfactory, it was felt that this observation of Lenher's which appeared to afford a new method of separation, should be studied further. The purpose of the present investigation was to determine

<sup>1</sup> Abstract of a portion of a thesis presented in partial fulfillment of the requirements for the degree of Doctor of Philosophy, in the University of Wisconsin, 1921. This work was financed in part by a grant from the University research fund.

<sup>2</sup> Lenher, *THIS JOURNAL*, 43, 29 (1921).

whether, and with what degree of accuracy, molybdenum trioxide and tungsten trioxide can be separated by means of selenium oxychloride, and to determine the best conditions for the separation.

**Basis of the Separation.**—The solubility of molybdenum trioxide in selenium oxychloride varies with the physical state of the oxide. The freshly precipitated hydrated oxide is readily soluble; the ignited oxide, on the other hand, is soluble only with difficulty, so that complete solution of a given sample cannot be effected in days or weeks. However, the addition of small amounts of sulfuric acid to the selenium oxychloride causes the ignited molybdenum trioxide to dissolve with ease. Hydrated tungsten trioxide, as is well known, is peptized readily by many substances, and as it happens to be peptized by selenium oxychloride, it passes into the colloidal condition. Ignited tungsten trioxide is neither dissolved nor peptized by selenium oxychloride with or without the addition of sulfuric acid. The basis of the separation, is therefore, the extraction of molybdenum trioxide with selenium oxychloride and sulfuric acid from a mixture of ignited molybdenum and tungsten trioxides.

**Method of Attack.**—To determine the best conditions for the separation, preliminary experiments were first conducted with each oxide separately. Weighed samples of molybdenum trioxide were boiled with the reagent in small Erlenmeyer flasks, the mouths of the flasks being covered with small watch glasses to prevent hydrolysis of the selenium oxychloride by the moisture of the air. One g. samples were employed, and the digestion was continued until solution was complete, or until no further action could be detected. The factors varied were the ratio of sulfuric acid to selenium oxychloride, and the volume of the solvent. Control experiments were conducted with tungsten trioxide, 1g. samples being digested with the reagent, the solution filtered through weighed Gooch crucibles with asbestos mats and the undissolved oxide transferred to the crucibles, ignited, and weighed. The amounts dissolved were thus determined by difference.

**Reagents.**—The oxides of molybdenum and tungsten were prepared by ignition of their ammonium salts which had been purified by repeated recrystallizations. Selenium oxychloride was prepared by the interaction of selenium dioxide and selenium tetrachloride,\* the product being distilled in a vacuum. The purity of the other reagents employed was ascertained by the customary tests.

#### Behavior of the Pure Oxides.

Preliminary experiments seemed to show that ignited tungsten trioxide was slightly soluble in selenium oxychloride and sulfuric acid. The losses, when 1g. samples were treated with 30 cc. of the solvent, amounted to several milligrams and their magnitude appeared to be independent of the composition or the volume of the reagent, and of the time of di-

\* Lenher, *THIS JOURNAL*, 42, 2498 (1920).

gestion. Examination of the selenium oxychloride filtrate and of the wash-water employed in transferring the undissolved oxide from the flask to the crucible showed that all of the dissolved oxide was contained in the latter. The losses were therefore due to peptization of the tungsten trioxide by the wash-water. It was found to be impractical to transfer the oxide to the crucible with a jet of selenium oxychloride, due to the rather high viscosity of the latter. Various solutions of electrolytes were employed for this purpose, and good results were obtained with a hot, 10% solution of ammonium nitrate. When this solution was employed the amount of tungsten trioxide dissolved was only a few tenths of a mg.

The experiments with tungsten trioxide having shown that this oxide is insoluble under all conditions in selenium oxychloride and sulfuric acid, the conditions for the separation could be adjusted solely with reference to dissolving the molybdenum trioxide. It was found that both the amount of solvent and the time required to effect the complete solution of a given sample of molybdenum trioxide decreased with increasing concentration of sulfuric acid in the reagent. Thus the time required to dissolve 1 g. of molybdenum trioxide in 30 cc. of solution containing 15 cc., 5 cc., and 2 cc. of sulfuric acid, was 30 minutes, 45 minutes, and 60 minutes, respectively. When the reagent contained less than 2 cc. of sulfuric acid per 30 cc. of solution, complete solution of 1 g. of oxide in 30 cc. of solvent could not be effected. It was found desirable to keep the sulfuric acid concentration low, as the viscosity of the reagent increases with increasing concentration of the acid. The reagent which was found to be most satisfactory, taking all factors into consideration, was a mixture of 1 part of sulfuric acid and 5 parts of selenium oxychloride. Thirty cc. of this reagent will dissolve 1 g. of molybdenum trioxide in 45 minutes at the boiling point of the solvent.

### Separation of Mechanical Mixtures.

The separation of mechanical mixtures of molybdenum and tungsten trioxides was next attempted. One-g. samples of known composition were boiled with 30 cc. of the reagent for an hour, the solution decanted through weighed Gooch crucibles, the residues washed several times with small portions of selenium oxychloride, and finally brought on the filter with hot, 10% ammonium nitrate solution. The crucible was ignited and weighed, the gain in weight representing tungsten trioxide. Molybdenum trioxide was determined by difference. The results of a few of these experiments, chosen at random from the large number of separations performed, are given in Table I.

It will be seen that the errors are in all cases small, which shows that the separation for molybdenum and tungsten with this reagent is a *very* accurate one.

### Separation of Intimate "Chemical" Mixtures.

The mixtures which were separated in the above experiments are not strictly comparable to those which are met with in actual practice. The samples which were separated in the experiments reported in Table I were simply mechanical mixtures of the ignited, finely ground oxides, while in actual practice the oxides would be obtained in a much more intimate state of admixture. Mixtures of tungsten and molybdenum trioxides are usually obtained by the ignition of their mercurous salts, precipitated together; by ignition of their ammonium salts, crystallized together; or by the decomposition of a mineral with aqua regia. When the separation of such mixtures (which may be called "chemical") prepared by dissolving known amounts of the oxides in ammonia, evaporating to dryness and igniting to oxide, was attempted, it was found that the separation proposed is of somewhat limited applicability. When the mixture contains more than about 10% of tungsten trioxide, complete extraction of the molybdenum cannot be effected, no matter how long the digestion is continued, or how much sulfuric acid is added to the selenium oxychloride. The molybdenum and tungsten trioxides apparently form a solid solution, the tungsten trioxide preventing the solution of the molybdenum trioxide unless the latter is present in large excess. When less than 10% of tungsten trioxide is present, the molybdic oxide can be completely extracted. In this case, however, the small amount of tungsten trioxide which was dispersed through the predominant molybdenum trioxide is left in a very fine state of division, and tends to run through the filter, causing serious losses. This difficulty was overcome by dissolving the mixed oxides in ammonia, and adding enough nitric acid to precipitate most of the tungsten, which thus had a chance to segregate from the molybdenum trioxide. The solution was then evaporated to dryness, and the residue ignited at dull red heat. Weighed samples of the mixed oxides so prepared were separated with selenium oxychloride and sulfuric acid as previously described. The results of these experiments are given in Table II.

These experiments show that the separation of these two oxides is possible by means of selenium oxychloride and sulfuric acid.

### Summary.

A new method has been described for the separation of molybdenum and tungsten, consisting in the extraction of molybdenum trioxide from a mixture of the ignited oxides by means of selenium oxychloride.

This work was performed by the writer while acting as research assistant to Professor Victor Lenher, whom the writer takes this occasion to thank for all his help and kindness.

## THE SPEED OF REACTION IN CONCENTRATED SOLUTIONS AND THE MECHANISM OF THE INVERSION OF SUCROSE.

BY GEORGE SCATCHARD.

Received July 27, 1921.

### Introduction.

Although the speed of inversion of sucrose in acid solutions has been studied more than the kinetics of any other reaction,<sup>1</sup> there are two anomalies which were discovered by the earliest workers, but which have not yet received an adequate explanation. According to the accepted theories of chemical kinetics, the speed of reaction ought to be independent of the concentration of sucrose and proportional to the concentration of the hydrogen ion. Experimentally, the speed increases more rapidly than the concentration of the hydrogen ion when that of the sugar is kept constant; and when the concentration of acid is unchanged the speed increases rapidly with increasing sugar concentration.

There have been three types of explanation of these anomalies offered. The one most generally accepted at the present time explains only the abnormal increase with increased acid concentration or on the addition of a salt. This theory assumes that the non-ionized acid exerts a catalytic effect, which may be even greater than that of the hydrogen ion itself.<sup>2</sup> However, this theory alone is not sufficient as is shown by the facts that it will not explain the change in speed with changing sugar concentration, and that different values are calculated for the activity of the non-ionized

<sup>1</sup> A good bibliography up to 1906 is given by R. J. Caldwell, *Brit. Assoc. Rep.*, (York), 1906, pp. 267-92.

<sup>2</sup> The following references are typical of a voluminous literature in this field.

acid from the effect of increasing acid concentration and from the effect of the addition of a salt with a common anion.<sup>3</sup>

A second method of explaining these anomalies is based on the assumption that the speed of reaction in solutions is not strictly proportional to the concentrations in moles per liter of the reactants. Wilhelmy,<sup>4</sup> the pioneer in this field, empirically divided the weight of acid by that of water and found the resulting speed much more nearly constant. Spohr<sup>5</sup> considered the effect due to the displacement of water by sugar, and he found that the speed of reaction was independent of the sugar concentration if the ratio of water to acid was kept constant. This method is equivalent to the use of the weight-normal concentrations of Morse,<sup>6</sup> and it has been much used by Armstrong and his co-workers.<sup>7</sup> Cohen<sup>8</sup> accomplishes practically the same result by making a correction for the volume occupied by the sugar, similar to the "b" term in van der Waals' equation. All these methods neglect the fact that the water takes part in the reaction.

The third type of explanation is that of Arrhenius<sup>9</sup> that the speed of reaction in solutions is proportional, not to the concentrations of the reactants, but to their osmotic pressures. The difficulty of this idea is the ambiguity of the osmotic pressure of a single component of a solution. At times the osmotic pressure seems to be identical with the activity as defined by G. N. Lewis,<sup>10</sup> and for such cases the theory of Arrhenius is identical with that which will be presented in this paper.

A great step in advance was made when Jones and Lewis<sup>11</sup> measured the activity of the hydrogen ion by means of the hydrogen electrode. Assuming that the speed of reaction is proportional to this activity of the hydrogen ion rather than to its concentration, they find it also proportional to the concentration of water in moles per liter, and they draw the conclusion that the reaction proceeds by the combination of a molecule of sugar with a hydrogen ion, and that this complex ion reacts with one molecule of water to form glucose and fructose and to re-form the hydrogen ion. The present paper is an extension of the substitution of activity for

concentration to the other reactants as well as to the hydrogen ion. The conclusions as to the mechanism of the reaction are very different from those of Jones and Lewis.

### The Formula for the Speed of Reaction in Solutions.

The formula for the speed of reaction in perfect gas systems is derived very simply from the kinetic theory: the speed is proportional to the concentration of each reacting species raised to the power which represents the number of molecules of that species which enter into the reaction according to the chemical equation. Given the reaction

the speed of reaction would be given by

$$s = dx/dt = K(C_1 - n_1'x)^{n_1}(C_2 - n_2'x)^{n_2}(C_3 - n_3'x)^{n_3} \quad (1)$$

where  $A_1$ , etc., represent the chemical formulas of the substances;  $n_1$ , etc., represent the number of molecules reacting; and  $n_1'$ , etc., represent the number of molecules which disappear when  $n$  molecules react.  $n_1'$  will be less than  $n_1$  when the substance  $A_1$  acts catalytically; it will be greater than  $n_1$  if  $A_1$  disappears in a subsequent reaction whose speed is greater than that of the reaction measured.  $C_1$ , etc., represent the initial concentrations in moles per liter;  $s$  is the speed of reaction;  $K$  is a constant of proportionality; and  $x$  is a concentration term of such magnitude that  $n_1'x$  is the number of molecules of  $A_1$  that have disappeared from one liter in time  $t$ . When applied to the speeds of the opposing reactions of a reversible process, this formula gives the same result for the equilibrium constant as that derived by thermodynamics.

The speed of reaction in liquid systems, however, is treated only by analogy. From van't Hoff's classic exposition of the similarity of *dilute* solutions to perfect gases, Equation 1 has been extended to *all* solutions. Historically, this formula was arrived at empirically by Wilhelm<sup>4</sup> for this same reaction long before van't Hoff's theories, but the great success of these simple views is responsible for its retention long after it had been found not to fit the facts.

Thermodynamics requires that the general expression for the equilibrium constant be in terms of the activities as defined by Lewis.<sup>10</sup> Since the ratio of the speeds of the opposing reactions of a reversible process must give the same equilibrium constant, it is a much more logical analogy to express the speed of a reaction (in a homogeneous system) in terms of activities. That is, the speed of any reaction in a homogeneous system is proportional to the activity of each reacting molecular species raised to the power which represents the number of molecules of that species which enter into the reaction according to the chemical equation. Lewis and Randall<sup>12</sup> have recently stated that this is a thermodynamic necessity for any reaction near equilibrium conditions.

<sup>12</sup> G. N. Lewis and M. Randall, *THIS JOURNAL*, **43**, 1150 (1921).

If we take the same chemical reaction as for Equation 1, the formula for the speed of reaction would be given by

$$s = K a_1^{n_1} a_2^{n_2} a_3^{n_3} \quad (2)$$

where  $a_1$ , etc., represent the activities of the various reactants, and the other symbols have the same meaning as before. Since we already have an undetermined factor of proportionality we can use relative activities, assigning unit activity to any desired state. However, we encounter difficulty in interpreting the quantity  $s$ . It must be measured by the number of molecules which react in unit time, but in what units should it be expressed? The answer to this question will be made simpler by the introduction of a new term—"semi-ideal solution."

By semi-ideal solution will be meant one in which the polarity or thermodynamic environment is independent of the concentration; it differs from an ideal solution in that there may be chemical reactions between the components, although it includes ideal solutions as a special case. A semi-ideal solution might also be called physically ideal, since all the variations from ideality are due to chemical changes. The chief characteristic of a semi-ideal solution is that the activity of each component is proportional to the molar fraction of that component which actually exists in the solution. Neither the number of moles of any component nor the total number of moles can be determined from the quantities added to the solutions; but, in many cases, the actual calculation of these quantities is unnecessary. The assumption of semi-ideality is customarily made in treating chemical action in solution, be it dissociation, association or compound formation, when the solution is considered as too concentrated for the simple laws of dilute solutions. Dolezalek<sup>13</sup> has gone so far as to claim that all solutions fulfil this condition. It is probable that most solutions are so nearly semi-ideal that the deviation from equality between activity and molar fraction is small.

For such solutions, as for ideal solutions, the quantity which is analogous to the volume of a perfect gas system is one mole of total substance, or the volume containing one mole. Replacing the total volume of a perfect gas system by the volume containing one mole of a semi-ideal liquid system is, at least approximately, the same as correcting the volume for the space occupied by all the molecules. If the polarity of the various kinds of molecules is the same, the forces of attraction and the distances between molecules will be independent of the nature of the molecules. Therefore the space between them will be approximately the same for any given number of molecules regardless of their size. But the space between the molecules is the free space, or the volume corrected for that part of it occupied by all the molecules, solvent as well as solutes. Then a dilute

<sup>13</sup> F. Dolezalek, *Z. physik. Chem.*, **64**, 727 (1908); see, however, J. J. vanLaar, *ibid.*, **72**, 723 (1910), and J. H. Hildebrand, *THIS JOURNAL*, **38**, 1457 (1916).

solution would be one in which the free volume is proportional to the total volume. If we must give up our picture of rigid molecules, and consider them as fields of force without any definite boundary where they can be said to end, this is probably as definite an idea of free space in a liquid system as we can obtain.

Pursuing our analogy to a perfect gas, we will consider that the speed  $s$  is measured by the number of molecules transformed in unit time in a volume which contains one mole of total substance. If  $x$  is the number transformed in time  $t$  in one liter, then  $s = \frac{1}{\Sigma C} \times \frac{dx}{dt}$ , where  $\Sigma C$  is the total number of moles per liter. Let us consider the special simple case where  $x$  is measured for the substance  $A_3$ , for which the solution is semi-ideal and for which  $n_3$  is equal to unity. The activity of  $A_3$  is  $a_3 = (C_3 - x)/\Sigma C$ , and Equation 2 becomes

$$s = \frac{1}{\Sigma C} \times \frac{dx}{dt} = K a_1^{n_1} a_2^{n_2} \left( \frac{C_3 - x}{\Sigma C} \right) \\ \text{or } dx/dt = K a_1^{n_1} a_2^{n_2} (C_3 - x). \quad (3)$$

It will be noted that  $a_1$  and  $a_2$  will in general be functions of the time or of  $x$ . For the third component we have reduced the formula to the same type as for perfect gases. If we can determine the functional relationship between  $a_1$ ,  $a_2$  and  $x$ , we will not be restricted to solutions which are semi-ideal to more than one component. Obviously for dilute solutions, where the activity is proportional to the concentration, Equation 3 reduces to Equation 1.

We have now an expression for the speed of reaction in terms of thermodynamic quantities. It is not, of course, a thermodynamic theory of chemical kinetics, for the equation is derived only by a reasonable analogy.

### The Inversion of Sucrose.

The inversion of sucrose as catalyzed by the hydrogen ion involves three reactants, sucrose, water and the hydrogen ion. If our formula is correct, its formulation when measured by the disappearance of sucrose is (from Equation 3),

$$dx/dt = K a_w^{n_w} a_h^{n_h} (C_s - x) \quad (4)$$

where the subscript (w) refers to water; the subscript (h) to the hydrogen ion and the subscript (s) to sucrose.

We can learn much about this reaction from the fact that, starting with any given concentration of sucrose and acid, the reaction gives a constant for a unimolecular reaction as measured by the disappearance of sucrose. Expressed mathematically,

$$\frac{dx}{dt} = k(C_s - x), \text{ or } k_s = \frac{1}{t} \ln \frac{C_s}{C_s - x}; \quad (5)$$

$k$  is the  $K_{uni}$  of Jones and Lewis, and is constant only for a single con-

centration of sugar and acid. The fact that  $k$  so determined is a constant shows that  $n_s$  is equal to unity, and that, for the special case where each molecule of sucrose which disappears is replaced by one of glucose and one of fructose, we are justified in replacing the activity of sucrose by its concentration. This is a matter of some importance since we have no direct means of measuring the activity of the sucrose. It also shows that the activities of the water and of the hydrogen ion may be considered as remaining constant during the course of the reaction. For the present we will assume that we can employ the same measure of the speed of reaction when the original concentration of the sugar is varied, and we will leave the justification of that assumption until we discuss the mechanism of the reaction.

The results of Palmaer<sup>14</sup> on solutions so dilute that the activity of the hydrogen ion is proportional to its concentration indicate that the speed of reaction is proportional to the first power of the hydrogen ion activity, or that  $n_h$  is also equal to unity. Unpublished work of Fales and Vosburgh and of Fales and Morrell, in which the activity of the hydrogen ion was measured directly, shows that this is also the case in the higher concentrations as studied by Jones and Lewis, and also shows that the hydrogen-ion activity does actually remain constant during the course of the reaction.

With these simplifications, Equation 4 becomes

$$dx/dt = K a_w^{n_w} a_h (C_s - x) \quad (6)$$

where  $x$  and  $t$  are the only variables. Integrating, this becomes

$$K = \frac{1}{a_w^{n_w} a_h} \times \frac{1}{t} \ln \frac{C_s}{C_s - x} \quad (7)$$

Comparing Equations 5 and 7, we see that

$$K = k / a_w^{n_w} a_h \quad (8)$$

If we can measure  $k$ ,  $a_w$ , and  $a_h$ , we can determine the value of  $n$  which gives a constant value of  $K$ , and so determine the number of molecules of water which enter into the reaction. Jones and Lewis<sup>11</sup> have measured  $k$  and  $a_h$  for solutions containing 10, 20, 30, 40, 50, 60 and 70 g. of sucrose per 100 cc. of solution and 0.1  $N$  with respect to sulfuric acid at 20° and at 40°. They have expressed the activity in terms of moles of hydrogen ion per liter; but, in order not to change the magnitude of our constants more than necessary, we will adopt the convention that the activity of the hydrogen ion in 0.1  $N$  solution of sulfuric acid in water alone is unity.

The activity of the water can be interpolated from the vapor-pressure measurements of Berkeley, Hartley and Burton.<sup>15</sup> Water vapor at or

<sup>14</sup> W. Palmaer, *Z. physik. Chem.*, **22**, 493 (1897).

<sup>15</sup> Earl of Berkeley, E. G. J. Hartley and C. V. Burton, *Phil. Trans.*, **218A**, 295 (1919).

below room temperature behaves so nearly like a perfect gas that the vapor pressure of an aqueous solution may be taken as an exact measure of the activity of the water in that solution. These authors have measured very accurately the vapor pressures relative to that of pure water at the same temperature. If we adopt the convention that the activity of pure water is unity, these measurements give directly the relative activities required.

**The Activity of the Water.**—The method of determining the activity of the water is given in considerable detail since other workers might wish to use the same method.

The first step is to interpolate to the concentrations used by Jones and Lewis, but still at 0° and 30°, the temperatures of the vapor-pressure measurements. To do this the concentrations of Jones and Lewis are recalculated in terms of g. of sucrose per 100 g. of water by using the number of moles of water per liter given in their paper. The interpolation was then made graphically by two methods: in the first the activity was plotted against the concentration; in the second the ratio,  $(1-a_w)/\text{conc.}$ , was plotted against the concentration. Each of these methods gave a graph of but slight curvature. Each curve was plotted twice on different scales, and the mean of the four determinations was taken as the best value. The greatest deviation of any individual value from this mean is 0.04% and the average deviation is less than 0.015%. The values of the activity used in plotting the curve are given in Table II (p. 2410) of the following article.

To determine the activities at 20° and at 40° from those at 0° and at 30°, the assumption is made that the relative activity is a linear function of the temperature. Since the maximum difference between 0° and 30° is 0.3%, this assumption cannot introduce an appreciable error. Table I gives the interpolated values at all four temperatures for solutions containing the same quantities of sugar as those used by Jones and Lewis but without sulfuric acid.

TABLE I.

INTERPOLATED ACTIVITIES OF WATER IN AQUEOUS SUGAR SOLUTIONS.

Concentration.		Activity ( $a$ ).			
G. of sugar per 100 cc.	100 g. of water.	0°.	30°.	20°.	40°.
0	0.0	1.0000	1.0000	1.0000	1.0000
10	10.70	0.9940	0.9944	0.9943	0.9945
20	22.93	0.9868	0.9875	0.9873	0.9877
30	37.05	0.9782	0.9791	0.9788	0.9794
40	53.39	0.9676	0.9687	0.9683	0.9691
50	72.93	0.9539	0.9552	0.9548	0.9556
60	96.37	0.9360	0.9377	0.9371	0.9383
70	125.70	0.9119	0.9149	0.9139	0.9150

It is next necessary to correct the activity of the water for the sulfuric acid present. There are no data available for the temperatures in question, but the decrease in activity is so small that we are justified in assuming that it does not change with the temperature and in calculating it from the freezing-point depression. Noyes and Falk<sup>16</sup> give the best value for the freezing-point depression of 0.05 *M* sulfuric acid as 0.2056°. Using the formula of Washburn<sup>17</sup> quoted by these same authors,  $1 - a_w = (p_0 - p)/p_0 = 0.00969 \Delta t (1 - 0.0043 \Delta t)$ , we obtain  $1 - a_w = 0.0021$ . This holds for zero sugar concentration.

The next step is to calculate the decrease in solutions containing sucrose. The most obvious assumption is the ordinary one for dilute solutions, that the decrease due to the sulfuric acid is the same for all solutions. This assumption undoubtedly gives too small values for the decrease, but calculations are made on this basis and will be designated as results according to the first assumption.

A better value can be obtained by treating the sugar solutions as semi-ideal solutions in which the degree of the ionization of the sulfuric acid is independent of the sugar concentration, the degree of association of the water is constant, and there is no polymerization of any other substance. Our symbols will be the same as before with the addition that:  $C_w$ ,  $a_w$ , etc., apply to solutions containing both sugar and acid;  $C'_w$ ,  $a'_w$ , etc., to solutions of sugar without acid;  $C''_w$ ,  $a''_w$ , etc., to solutions of acid without sugar; the subscript (<sub>w</sub>) to monohydrol and the subscript (<sub>p</sub>) to polymerized water;  $N_o$  is the molar fraction of monohydrol in pure water.

The sucrose in solution may be partially hydrated and partially not, but the total concentration of all its forms will be the amount of sucrose added per liter,  $C_s$ . The sulfuric acid will exist as  $H_2SO_4$ ,  $HSO_4^-$ ,  $SO_4^{--}$  and  $H^+$ , any one of which may be hydrated to various degrees. But the sum of the first three will always equal the quantity of sulfuric acid added, 0.05 moles per liter; the quantity of hydrogen ion per liter will be  $C_h$ . The activity of monohydrol in pure water is one, but its molar fraction is  $N_o$ . So in any solution the activity of monohydrol is equal to the molar fraction divided by  $N_o$ . The molar fraction of polymerized water in pure water is  $1 - N_o$ . Since the ratio of molar fractions of monohydrol and polymerized water is constant, the following holds true for all solutions.

$$\frac{C_p}{C_w} = \frac{N_p}{N_w} = \frac{1 - N_o}{N_o}, \quad C_p = \frac{C_w(1 - N_o)}{N_o} \quad \text{and} \quad C_p + C_w = C_w/N_o$$

The total number of moles per liter will be,

$$C_w + C_p + C_h + C_s + 0.05 = C_w/N_o + C_h + C_s + 0.05.$$

From the hypothesis that the activity of each substance is equal to its molar fraction we have,

<sup>16</sup> A. A. Noyes and K. G. Falk, *THIS JOURNAL*, 32, 1013 (1910).

<sup>17</sup> E. W. Washburn, *Technology Quart.*, 21, 373 (1908).

$$\begin{aligned}
\frac{C_w/N_o N}{C_w/N_o + C_s} &= a'_w; \quad \frac{C'_w N_o}{C'_w/N_o + C_h + 0.05} = a''_w; \quad \frac{C_h}{C'_w/N_o + C_h + 0.05} = a''_h; \\
\frac{C_w/N_o}{C_w/N_o + C_h + C_s + 0.05} &= a_w; \quad \frac{C_h}{C_w/N_o + C_h + C_s + 0.05} = a_h \\
\text{since } \frac{C'_s}{C'_w/N_o} &= \frac{C_s}{C_w/N_o}, \text{ and } C'_h = C_h, \\
1 - a''_w &= 1 - \frac{C'_w/N_o}{C'_w/N_o + C_h + 0.05} = \frac{C_h + 0.05}{C'_w/N_o + C_h + 0.05} \\
a'_w - a_w &= \frac{C_w/N_o}{C_w/N_o + C_s} - \frac{C_w/N_o}{C_w/N_o + C_h + C_s + 0.05} \\
&= \frac{C_w/N_o (C_h + 0.05)}{(C_w/N_o + C_s)(C_w/N_o + C_h + C_s + 0.05)} \\
&= \frac{C_w/N_o}{C_w/N_o + C_s} \times \frac{C_h + 0.05}{C_w/N_o + C_h + C_s + 0.05} \\
&= \frac{C_w/N_o}{C_w/N_o + C_s} \times \frac{C_h + 0.05}{C'_w/N_o + C_h + 0.05} \times \frac{\frac{C_h}{C'_w/N_o + C_h + 0.05}}{\frac{C_h}{C'_w/N_o + C_h + 0.05}} \\
&= a'_w \times (1 - a''_w) \left( \frac{a_h}{a''_h} \right) \quad (9)
\end{aligned}$$

or the decrease in the activity of the water in a sugar solution due to the sulfuric acid is equal to the decrease in the solution without sugar multiplied by the activity of the water in the sugar solution without acid and by the activity of the hydrogen ion in the final solution relative to that of an acid solution of the same concentration in the absence of sugar. Table II gives the activity of the hydrogen ion in the various solutions relative to that of 0.1 *N* sulfuric acid in pure water as unity, and the decrease in the activity of the water due to the sulfuric acid as calculated by Equation 9. Probably this decrease is a trifle too large. We will find later that the sugar solutions behave like semi-ideal solutions in which the degree of ionization of the sulfuric acid increases a little with increasing sugar concentration; and, assuming that whatever causes the apparent increased ionization would have the same effect on the activity of the water as though the increase were real, this would tend to give values for the decrease a little too large. Values calculated from these decreases are designated as results according to the second assumption.

The values of the activity of the water used in Tables III, etc., are rounded off to three places. The calculations are made on both assumptions since the true value probably lies between the two. The author believes that the final values of the activity as calculated by the second assumption are correct to one or two parts per thousand.

It is interesting to compare the calculated decrease in activity with the measurements of Rivett<sup>18</sup> on the effects of various salts. Rivett measured the freezing points of 77 solutions of 14 salts in concentrations ranging from 0.1 *N* to *N* with respect to the salt and up to 40 g. of sugar per 100 g. of water. The different salts should not be expected to behave exactly like the sulfuric acid, but might be expected to have a somewhat similar behavior. The relative depression in the presence and in the absence of sugar is within the limits set by our two assumptions in all but 10 cases. Of these 5 are apparently errors in measurement or in tabulation, since they differ widely from the other results on the same salts. The other 5 are concentrated copper sulfate solutions, which appear to give regularly higher values than the sulfuric acid. The 67 values which fall within the limits are distributed nearly uniformly between the two.

**The Order of the Reaction with Respect to the Water.**—To determine the number of water molecules which enter into the reaction, we use Equation 8 and substitute various integral values for  $n_w$  to determine which will give constant values of  $K$  independent of the sugar concentration. Tables III A and IV A gives these values at 20° and 40° according to the first assumption.  $K_1$  is the value of  $K$  when  $n_w$  equals 1;  $K_5$  when  $n_w$  equals 5, etc. Tables III B and IV B give the corresponding results when  $a_w$  is calculated according to the second assumption. The values of  $k$  and  $a_h$  are, of course, the same for either assumption. In the B tables,  $C_w$  is the concentration of water divided by that in 0.1 *N* sulfuric acid without sugar—the relative concentration of the water—and  $K_c$  in the last column is  $\frac{k}{a_h \times C_w}$ . This is the value of  $K$  derived by Jones and Lewis multiplied by the number of moles per liter of water and of hydrogen ion in 0.1 *N* sulfuric acid without sugar; these values are included for comparison.

It is evident that when  $n_w=1$ , the values of  $K$  decrease rapidly with increasing sugar concentration. It is necessary to raise the activity of

<sup>18</sup> A. C. D. Rivett, *Medd. K. Vetenskapsakad. Nobelinst.*, 2, No. 9 (1911).

the water to a much higher power. The results are tabulated for  $n_w = 5$ , 6 and 7. The values of  $K_5$  still decrease, those of  $K_7$  increase, while those of  $K_6$  remain sensibly constant.

The average values of the  $K$ 's are given, and the square root of the mean of the squares of the deviations of the individual values from the average value is given in the row designated R. M. S. D. (root mean square deviation). This is the best method of determining constancy. The values for zero concentration of sugar are given in parentheses, but they are not used in calculating the average values since the corresponding value of  $k$  is obtained by extrapolation.

It is clear that the values of  $K_6$  are much more nearly constant than those of  $K_5$  or  $K_7$ , and this conclusion is independent of the assumption as to the effect of the acid on the activity of the water, showing that a small error introduced by these assumptions will not affect the conclusions. The results at 40° are not so sharply conclusive as those at 20°. Apparently the experimental results are considerably less accurate due to the greatly increased speed of reaction, and the experimental errors introduce a variation of nearly the same magnitude as the differences between the results for  $K_5$ ,  $K_6$  and  $K_7$ . However,  $K_6$  is still the best constant.

These results show conclusively that, if our conception of the speed of reaction is correct, a large number of molecules of water enter into the reaction. In order to establish that this number is 6 rather than 5 or 7 and that the number is independent of the sugar concentration, etc., a larger number of experiments with various acids at different concentrations will be necessary. Professor Fales has kindly consented to direct his work on sucrose inversion to a thorough test of the theory. To make the following discussion clearer we will assume that 6 molecules of water enter into the reaction, while we recognize that more complete results may change this number slightly. But such a change will not greatly change the nature of the discussion. If it be found that 7 molecules react rather than 6, the discussion will hold true if 7 be substituted for 6 wherever it occurs.

**The Mechanism of the Reaction.**—With 6 molecules of water taking part in the reaction, the number of possible ways of picturing the mechanism is very large. It seems probable, however, that the activity of the hydrogen ion in catalysis is the same as its activity measured by the hydrogen electrode. Then the 6 water molecules must react with the sugar or with a complex of sugar and the hydrogen ion. Jones and Lewis come to the conclusion that the sucrose and the hydrogen ion react to form a complex ion which then reacts with the water according to the equation,

$$C_{12}H_{22}O_{11} + H^+ \rightleftharpoons C_{12}H_{22}O_{11} \cdot H^+; \quad C_{12}H_{22}O_{11} \cdot H^+ + H_2O \longrightarrow \underset{\text{glucose}}{C_6H_{12}O_6} + \underset{\text{fructose}}{C_6H_{12}O_6} + H^+.$$

If a large number of water molecules react instead of only one, this mechanism shows no reason why it should be 6 independent of the temperature and sugar concentration. The saccharated hydrogen ion also seems improbable, because, if it existed in the solution to any extent, it should reduce the activity of hydrogen ion in concentrated sugar solutions. It is much more probable that the water molecules react with the sugar first, and that this hydrate of sucrose then reacts with a hydrogen ion to give glucose, fructose and the hydrogen ion again, according to the equation:

These results cannot show whether the action of the hydrated sugar and the hydrogen ion is to form an intermediate complex ion or not.

**The Activity of the Sugar.**—If this picture of the mechanism of the reaction is correct, the reaction whose speed we are really discussing is the disappearance of the anhydrous (unhydrated) sugar. Also, if the measurements of the extent of hydration<sup>19</sup> in the following paper are even approximately correct, we cannot assume that the sugar is almost all either hydrated or unhydrated; but both forms exist in our solutions to a considerable extent and their relative quantities vary widely with the concentration. It is necessary, then, to question critically our use of the disappearance of total sugar as a measure of the speed of reaction.

We will let the subscript (anh) apply to the anhydrous (unhydrated) sugar, and the subscript (hyd) apply to the hydrate. Then  $C_s = C_{anh} + C_{hyd}$ , and similarly for the other properties. The equations we used as a measure of the speed of reaction are

$$\frac{dx}{dt} = K a_w^n a_h (C_s - x), \quad (6)$$

$$\text{and} \quad K = \frac{1}{a_w^n a_h} \times \frac{1}{t} \ln \frac{C_s}{C_s - x}. \quad (7)$$

The corresponding equations for the disappearance of anhydrous sugar are

$$dy/dt = K a_w^n a_h (C_{anh} - y), \quad (10)$$

$$\text{and} \quad K = \frac{1}{a_w^n a_h} \times \frac{1}{t} \ln \frac{C_{anh}}{C_{anh} - y} \quad (11)$$

where  $y$  is the quantity of anhydrous sugar which disappears from one liter in time  $t$ .

$$\text{The } K\text{'s will be identical in case } \frac{C_s - x}{C_s} = \frac{C_{anh}}{C_{anh} - y}. \quad (12)$$

Let us consider the hydration of sucrose from the viewpoint of the law of mass action expressed in terms of activities, the holding of which is a thermodynamic necessity if the substances exist at all.

<sup>19</sup> "Extent of hydration" is used to indicate the fraction of the sugar molecules hydrated; "degree of hydration," the number of molecules of water combined with one of sugar in the hydrate.

$$K_{\text{hyd}} = \frac{a_{\text{hyd}}}{a_{\text{anh}} \times a_w^6}, \text{ or } \frac{a_{\text{hyd}}}{a_{\text{anh}}} = K_{\text{hyd}} a_w^6 \quad (13)$$

$$\frac{a_{\text{hyd}} + a_{\text{anh}}}{a_{\text{anh}}} = \frac{a_s}{a_{\text{anh}}} = 1 + K_{\text{hyd}} a_w^6. \quad (14)$$

If, during the course of a single reaction, the activity of the water is constant, the right-hand side and therefore the left-hand side of Equation 14 will be constant. Now let us assume that the solutions are semi-ideal with respect to the hydrated and unhydrated sugar. Then for the activities we may substitute molar fractions, and we have,

$$\text{const.} = \frac{a_s}{a_{\text{anh}}} = \frac{N_s}{N_{\text{anh}}} = \frac{\frac{C_s}{\Sigma C}}{\frac{C_{\text{anh}}}{\Sigma C}} = \frac{C_s}{C_{\text{anh}}}. \quad (15)$$

If we substitute the values of  $C$  at time zero and time  $t$ , we have,

$$\frac{C_s}{C_{\text{anh}}} = \frac{C_s - x}{C_{\text{anh}} - y}, \text{ or } \frac{C_s}{C_s - x} = \frac{C_{\text{anh}}}{C_{\text{anh}} - y},$$

which is identical with Equation 12. We are therefore justified in taking the rate of disappearance of the total sucrose as a measure of the speed of disappearance of anhydrous sucrose when the activity of the water remains constant.

But the assumption of constant activity of the water is not in accord with experiment. Invert sugar depresses the activity of water very nearly twice as much as the sucrose from which it is derived, and this fact has been used to follow the course of the reaction by the change in boiling point<sup>20</sup> and in freezing point.<sup>21</sup> For the most concentrated solutions the activity of the water would be reduced about 1/10 during the course of the reaction. This would mean that our integration of Equations 6 and 10 with the assumption of constant activity of the water is not exact. Equations 14 and 15 still hold, however, and combining them we have,

$$C_s/C_{\text{anh}} = 1 + K_{\text{hyd}} a_w^6 \quad (16)$$

Then, as the activity of the water decreases, the ratio of anhydrous to total sugar will increase. This will cause an acceleration of the reaction when measured in terms of the disappearance of total sugar (Equation 6) which will tend to compensate for the retardation due to the decreased activity of the water, and there will be a smaller error in assuming the activity of the water to be constant than if Equation 10 itself were used.

It does not seem worth while to follow the analysis of this factor more rigorously, since there are at least two other factors which tend to produce a variation in  $k$  as determined by the optical rotatory power. The first

<sup>20</sup> J. E. Trevor and F. C. Kortright, *Z. physik. Chem.*, **14**, 149 (1894).

<sup>21</sup> L. Kahlenberg, D. J. Davis and R. E. Fowler, *THIS JOURNAL*, **21**, 1 (1899).

is the mutarotation of the products of inversion;<sup>22</sup> the second, the reversion<sup>23</sup> or slow change in the final rotation which makes it difficult to determine the true end-point. This reversion is apparently due, in part at least, to a recombination of the glucose and fructose to disaccharides other than sucrose.

Worley made some very careful measurements and determined the change in  $k$  with time by using Equation 5 integrated between the limits  $t_1$  and  $t_2$ , which gives the formula,

$$k = \frac{1}{t_2 - t_1} \ln \frac{C_s - x_1}{C_s - x_2} \quad (17)$$

This formula has the single disadvantage that it multiplies the experimental error, since the time intervals must always be small. Worley found that for his experiments the total effect of the interfering factors was to give increasing values of  $k$ , while the decrease in the activity of the water would tend to give decreasing values.

Our problem is not to determine the exact kinetics of this reaction, actually of the eighth order and complicated by subsequent reactions, but simply to ascertain whether the value of  $k$  as calculated from the experimental results is really the  $k$  we have used in Equation 8. This will be true if the experimental  $k$  is the initial  $k$ —that at the beginning of the reaction—when the activity of the water has not appreciably changed and may be regarded as constant. A sufficient condition will be that  $k$  as determined by Equation 17 does not vary during the reaction.

Jones and Lewis give only one pair of results from which this condition may be tested, those for 70 g. of sucrose at 40°. These results are, however, the ones most likely to give a variation in  $k$ , since the activity of the water changes most for the concentrated solutions. Table V gives the constants for two duplicate experiments calculated by Equation 17 and by Equation 5. Those by Equation 17 are tabulated in the same row as  $t_2$ , while  $t_1$  is the next preceding time. It will be seen that the value of  $k$  from Formula 17 shows no systematic trend and that the average is practically the same as that calculated from Formula 5. Due to the magnification of the experimental errors with the shorter time intervals, the variation in the individual values is considerably greater for Formula 17. The results show that we are justified in using in Equation 8 the values of  $k$  as measured by Jones and Lewis.

The Activity of the Hydrogen Ion.—Jones and Lewis account for the increased activity of the hydrogen ion in the concentrated sugar solutions by a difference in the catalytic environments of sucrose and of water. Since the activity (as measured by the catalytic effect) does not change during the course of the reaction, the catalytic effect of the sucrose must be the same as that of the corresponding amount of invert sugar, and they therefore assume that it is zero, and that the whole change is due to the negative catalytic effect of the water. This they find expressible as an exponential function of the water concentration.

A very simple explanation is obtained from the view of semi-ideal solutions. If this view is correct, the activity of the hydrogen ion is proportional to its molar fraction, and the great change with changing sugar concentration is due to a change in the number of total moles per liter. By using the activity of the water and that of the hydrogen ion and applying the concept of a semi-ideal solution in which the degree of association of the water remains constant and no other substances are polymerized, it is possible to calculate the concentration of hydrogen ions in moles per liter. For the water we have,

$$\frac{C_w/N_o}{C_w/N_o + C_h + C_s + 0.05} = a_w; C_w/N_o = \frac{a_w}{1-a_w} (C_h + C_s + 0.05).$$

According to our convention, the activity of the hydrogen ion is not equal to its molar fraction, since we have assigned unit activity, not to a solution of unit molar fraction, but to a water solution of 0.1 *N* sulfuric acid. However, the activity will be proportional to the molar fraction, and we will let *K* be the proportionality constant.

$$\frac{C_h}{C_w/N_o + C_h + C_s + 0.05} = K a_h$$

Substituting the value of  $C_w/N_o$  obtained above and solving for  $C_h$ , we have

$$C_h = \frac{K a_h}{1-a_w-K a_h} (C_s + 0.05). \quad (18)$$

The value of  $K$  may be obtained for each temperature by solving the equation for the solution without sugar where the hydrogen-ion concentration is known. At  $20^\circ$ ,  $C_h=0.06$ ,  $a_h=1$ ,  $a_w=0.998$ ,  $C_s=0$ ; at  $40^\circ$ ,  $C_h=0.05$  and the others have the same values as at  $20^\circ$ . Table VI gives the values of the hydrogen-ion concentration calculated from Equation 18 at  $20^\circ$  and at  $40^\circ$ . In each case the values are calculated according to both assumptions as to the effect of the sulfuric acid on the activity of the water. The fact that the results are only a few per cent. different in the two cases shows that, even though the form of the mathematical equations is similar to those used in calculating the change in activity according to the second assumption, the results cannot depend upon that assumption.

TABLE VI.

CONCENTRATION OF HYDROGEN IONS IN AQUEOUS SUGAR-SULFURIC ACID SOLUTIONS.

Conc. of sugar.	20°.		40°.	
	1st assumpt.	2nd assumpt.	1st assumpt.	2nd assumpt.
0	0.060	0.060	0.050	0.050
10	0.062	0.062	0.056	0.056
20	0.066	0.066	0.062	0.057
30	0.070	0.067	0.067	0.064
40	0.072	0.070	0.071	0.067
50	0.072	0.069	0.075	0.070
60	0.073	0.071	0.076	0.073
70	0.072	0.070	0.077	0.073

Since the solutions are 0.1  $N$ , multiplication of the hydrogen-ion concentration by 1000 will give the degree of ionization of the sulfuric acid in percentages. In each case the degree of ionization increases with increasing sugar concentration, but the increase is not very large, and for the more concentrated solutions it disappears within the rather large experimental error. This error is due to the fact that the hydrogen-ion concentration is calculated from small differences. A slight variation of the solutions from semi-ideality or a different assumption as to the degree of ionization without sugar would also change the table somewhat. If allowance were made for the smaller degree of association of the water in the solutions where its molar fraction is smaller, the concentration of hydrogen ion in the more concentrated solutions would be reduced. Certainly these results are too few for theorizing on the efficiency of water and of sugar solutions as ionizing media except to point out that they are not very different, and that we have eliminated the anomaly of an ionization greater than 100%.

Jones and Lewis reduced the negative catalytic effect of water on the inversion of sucrose as observed by Rosanoff and Potter<sup>24</sup> to a catalytic

<sup>24</sup> M. A. Rosanoff and H. M. Potter, *THIS JOURNAL*, 35, 248 (1913).

effect on the ionization of the acid. Our interpretation of the nature of sugar solutions reduces it to a difference in molar volume between sucrose and water. The fact that it may be expressed as an exponential function of the water concentration can give no new information on the nature of anticatalytic action.<sup>25</sup>

**The Relation to the Neutral Salt Effect.**—If this theory as to the dependence of the speed of reaction on the activities of the reactants is correct, the effect of a neutral salt on the speed of reaction should be a complicated one. The addition of a neutral salt will affect the activity of each component. The activity of the water will be decreased as is shown by the decrease of vapor pressure or corresponding change in the other colligative properties. The activity of the hydrogen ion will be increased, as has been shown by the work of many observers.<sup>26</sup> Most of these observers interpret the effect as due to a decrease in the apparent volume of the solvent. In the terms of our theory this would mean an increase in the molar fraction of the hydrogen ion due to a decrease in the number of moles of water. Lack of knowledge of the degree of dissociation of the added salts prevents an analysis of this effect similar to that made on the sugar solutions to determine whether these solutions may also be interpreted as semi-ideal.

The effect of the salt on the activity of the sucrose has never been measured, but it would probably increase it. By decreasing the activity of the water it would decrease the extent of hydration of the sucrose. It is also a general characteristic of salts that they increase the activity of organic

<sup>25</sup> A paper by Garner and Masson (*Phil. Mag.*, 41, 484-6 (1921)) on this subject has just come to the author's attention (September 29, 1921). They note that the ratio between the activity of hydrogen ions in a sugar solution and in pure water is approximately equal to the ratio between the osmotic pressure of the solution and that calculated by van't Hoff's Law and to the inverse ratio of the solubility of hydrogen in that solution and in pure water. They explain all three by the removal of water, probably to form a hydrate of sucrose. The assumptions upon which this is based for the solubility of gases are discussed in the following paper. For the osmotic pressure it must be assumed that the Morse formula gives an accurate expression for the osmotic pressure of an ideal solution; this is probably correct within the limits of their approximations. For the hydrogen ion activity one must assume that the activity of the hydrogen ion is inversely proportional to the quantity of water in which it is dissolved and independent of the other components of the solution. The present author can see no reason for assigning this unique position to water. It would certainly lead to astonishingly large results for the activity of hydrogen ion in nearly anhydrous alcohol or glycerine.

solutes, as shown by the decreased solubility and coefficient of partition with organic solvents.<sup>27</sup>

It will be necessary to include all these effects in the consideration of neutral salt action. This becomes particularly important in the determination of the catalytic effect of the non-ionized acid. If this is to be calculated from the change in catalytic effect with changing acid concentration or on the addition of neutral salts, all the factors must be taken into consideration. It is not sufficient to follow the customary procedure of assuming the activity of the water and of the substrate to remain constant and to calculate the activity of the hydrogen ion from the law of mass action in terms of concentrations. The writer does not desire to question the existence of a catalytic effect of non-ionized acid, which, for certain reactions, seems to be firmly based on a variety of grounds, but he does wish to question the ordinary methods of calculating the relative catalytic effect of non-ionized acid and hydrogen ion.

Arrhenius and Andersson<sup>9</sup> have studied the neutral salt effect on sucrose inversion from their viewpoint of osmotic pressures, and conclude that there is no evidence for a catalytic action of the un-ionized acid. Their osmotic pressure of the hydrogen ion is the same as its activity and is calculated with some extrapolation from the hydrogen-electrode measurements of Harned; the osmotic pressure of sugar they calculate from freezing-point measurements by a method which seems to me entirely unjustified; and they ignore the part of the water in the reaction. At present there are not enough data available for the analysis of this very important problem.

### Summary.

1. A method has been outlined for calculating the activity of water in sugar solutions of any concentration at temperatures near room temperature. The method has also been extended to solutions containing a small amount of other solute (sulfuric acid).

2. A formula for the speed of reaction in solutions in terms of the activities of the reactants is developed and suggested as the most logical formula for solutions.

3. By the application of this formula to the inversion of sucrose it is shown that the available data indicate that the reaction is of the sixth order with respect to water.

4. The results are interpreted as indicating the existence of a hexahydrate of sucrose.

5. The effect of the addition of sugar in increasing the activity of the hydrogen ion is explained as being very largely due to an increase in the

<sup>27</sup> For ethyl acetate: H. Lunden, *Medd. K. Vetenskapsakad. Nobelinst.*, **2**, No. 15 (1911); for benzoic and salicylic acids: B. de Szyszkowski, *ibid.*, **2**, No. 41 (1913).

molar fraction of hydrogen ions without any large change in the actual degree of ionization.

6. A warning is given concerning the customary method of calculating the catalytic effect of un-ionized acid.

In conclusion the author wishes to express his hearty thanks to Professor H. A. Fales and Mr. J. C. Morrell for their courtesy in giving him access to unpublished work.

## THE HYDRATION OF SUCROSE IN WATER SOLUTION AS CALCULATED FROM VAPOR-PRESSURE MEASUREMENTS.

BY GEORGE SCATCHARD.

Received, July 27, 1921.

### Introduction.

The determination of the existence of hydrates of sucrose in its aqueous solutions and the calculation of the average degree of hydration of the sucrose have been made from various properties of these solutions. Jones and Getman,<sup>1</sup> Callendar,<sup>2</sup> Washburn<sup>3</sup> and Bousefield<sup>4</sup> calculated the degree of hydration from the freezing point; Bousefield, Frazer and Myrick<sup>5</sup> and Porter<sup>6</sup> used the osmotic pressure; and Philip,<sup>7</sup> the solubility of hydrogen in sugar solutions. Einstein<sup>8</sup> concluded from a kinetic treatment of viscosity that the sugar must be very heavily hydrated, but he did not determine the degree.

The calculation of hydration from the solubility of a gas depends on two assumptions: that the power to dissolve hydrogen of a given mass of water is independent of anything with which it may be mixed, and that the dissolving power of sucrose and of the hydrates of sucrose is zero. The principal justification for these assumptions is that, in the case of cane sugar and chloral hydrate, they give results in agreement with those from the colligative properties.

Washburn<sup>3</sup> gives a very good review of hydration in solution, and notes that the colligative properties do not give mutually independent measures of the degree of hydration. The most rigorous treatment of either the

osmotic pressure or the freezing point is to calculate the activity of the water by thermodynamic formulas and calculate the degree of hydration by assuming that this activity is proportional to the molar fraction of the water. That is, it is assumed that the solution is semi-ideal as defined in the previous paper.<sup>9</sup> This is the method used by Callendar, by Washburn and by Frazer and Myrick. Jones and Getman and Bousefield use the simpler method of calculating the hydration from the variation of the freezing point from Raoult's formula, which really involves the above assumption and in addition that of infinite dilution.

The assumptions made by Bousefield and by Porter in their treatments of osmotic pressure are quite different, but they both arrive at the formula  $P(V-B) = RT$  as the exact one for osmotic pressure. Bousefield calculates the degree of hydration by taking  $V-B$  as the volume of free water, with its density the same as that of pure water. Porter takes  $B$  as the volume of the hydrate and assumes that the densities of the sugar and water in the hydrate are the same as those of the pure substances. When they both start from the same experimental results,<sup>10</sup> Bousefield's calculations range from 85 to 95% of Porter's. Possibly most of this difference is due to different approximations of experimental values. We will not analyze their assumptions in detail since the same formula can be obtained from a great many different assumptions, and most of them must be wrong because they are mutually exclusive. But they all need the fundamental assumption that the forces of attraction are independent of the concentration, the condition which we found sufficient for semi-ideal solutions.

The exact calculation of the activity from the osmotic pressure requires a knowledge of the densities and the compressibilities of the solutions; the calculation from the freezing point requires the latent heat of fusion of ice and its temperature variation. The results are so uncertain that Washburn, Callendar and Frazer and Myrick do not attempt to calculate the degree of hydration exactly, but they assign different integral values to the hydration and calculate the corresponding freezing point or osmotic pressure to determine which value for the hydration agrees best with the experimental results. Washburn found that the results of several observers on rather dilute solutions were fitted by the assumption of a hexahydrate. Callendar used the measurements of Jones and Getman on more concentrated solutions and found that a pentahydrate gave more satisfactory results. Frazer and Myrick studied a much larger concentration range and found that a hexahydrate gave best agreement for the dilute solutions, a pentahydrate for intermediate concentrations and a tetrahydrate for the most concentrated solutions.

<sup>10</sup> Those of Morse and Frazer at 20°. *J. Chem. Soc.*, 105, 604 (1914); *Trans. Faraday Soc.*, 13, 129 (1917).

Vapor-pressure measurements have the advantage over the other colligative properties that they give the activity directly. They have the further advantage over the freezing point that they give results at constant temperature, and the effect of varying concentration can be determined directly. The accurate vapor-pressure measurements of Berkeley, Hartley and Burton<sup>11</sup> at 0° and 30° give us the most exact means of determining the hydration of sucrose. They are used in the calculations of this paper.

#### Analysis of Assumptions.

Since we are to attempt to determine the degree of hydration with considerably greater accuracy than has been done hitherto, it is necessary to examine our assumptions rather closely. If the activity of the water is proportional to its molar fraction, the polarity or thermodynamic environment of the solution must be independent of the concentration. This means that the forces of attraction acting on any molecule must be independent of the kind of molecules surrounding it. A water molecule must have the same forces exerted on it when it is entirely surrounded by other water molecules as when it is entirely surrounded by sugar molecules or as when it is surrounded by any mixture of the two. These mutual forces depend upon the fields of force surrounding the individual molecules.

The field of force of a sugar molecule ought to be similar to that of a water molecule, or rather to a string of water molecules. The carbon atoms must be nearly surrounded by the hydrogen atoms and hydroxyl groups, and the sugar molecule ought to be represented by a nearly uniform field of force due to the hydrogen and hydroxyl radicals in equal numbers. But these are, of course, the same groups as those of the water molecules, and the fields of force of a sugar molecule ought to be very similar to that of the water molecules which it displaces in solution. Although these forces are very much greater than those in organic liquids, if they are the same for sugar and for water, aqueous sugar solutions ought to obey the laws of semi-ideal solutions as accurately as do mixtures of two hydrocarbons. Certainly, carbohydrates ought to obey these laws much more closely than most other solutes, especially ionogens, which have quite different force fields. It seems that we are justified in assuming that all the variation from ideality is due to chemical action and that the molar fraction of the water is proportional to its activity.

We must next consider the ways in which the number of molecules of each substance in solution may change from the number added. The dissociation of both water and sugar may certainly be neglected. We will assume that any association of sugar may also be neglected; this is fairly well justified since the molar fraction of sugar is always less than 12%. Then there are but two kinds of chemical change possible: combination between two or more molecules of water, and between one of sugar and one or more of water. The extent of this latter reaction is what we are seeking to determine, and this makes it necessary to know the extent of the former. It is generally agreed that liquid water is partially associated into dihydrol ( $\text{H}_2\text{O}$ )<sub>2</sub> and perhaps a little trihydrol ( $\text{H}_2\text{O}$ )<sub>3</sub>, and various calculations have been made of the extent of association. It seems that these are generally high, and that most of the properties which are customarily taken as evidence for association can be more simply accounted for by the larger forces of attraction between the molecules. However, it is a surprising fact that the assumption as to the degree of association of the water makes very little difference in the determination of the degree of hydration of the sucrose. Washburn

<sup>11</sup> Earl of Berkeley, E. G. J. Hartley and C. V. Burton, *Phil. Trans.*, 218A, 295 (1919).

and Callendar assume that there is no association, Frazer and Myrick assume that all the water exists as dihydrol, and their conclusions are not very different.

We will make our calculations on two assumptions, which seem the limits of probability. First, we will assume that there is no association; second, that the association is approximately that calculated by van Laar<sup>12</sup> by the Ramsay-Ross Innes formula, 1.7 at 0° and 1.6 at 30° into dihydrol. That is, the molar fraction of monohydrol is 0.3 at 0° and 0.4 at 30°. The degree of association will not be the same in the sugar solutions as in pure water but will obey the law of mass action. Also, in the case of association, the molar fraction of water will not equal its activity relative to that of pure water as unity, but the activity must be multiplied by the molar fraction of monohydrol in pure water.

**Symbols.**—For convenience of reference the symbols used in this paper are collected and defined here. We will let subscripts *w*, 1, 2, *s*, *anh* and *hyd* refer to water, monohydrol, dihydrol, total sugar, anhydrous (unhydrated sugar) and hydrated sugar, respectively; *N* is the molar fraction existing in solution; *N'*, the molar fraction added; *N<sub>0</sub>*, the molar fraction of monohydrol in pure water; *a*, the activity; *a<sub>w</sub>*, the activity of monohydrol in terms of pure water as unity; *C*, the concentration of sucrose in grams per 100 g. of water; and *m* the number of molecules of water in one of sucrose hydrate.

**Derivation of Formulas.**—The calculation of the average degree of hydration is very simple for the case without association. From the number of grams of sugar added per 100 g. of water we calculate the number of moles of water added to one mole of sugar,

$$\frac{N'_w}{N'_s} = \frac{100 \times 342.24}{C \times 18.016} \quad (1)$$

The number of moles of water existing in solution for each mole of sucrose is the ratio of their molar fractions; and, since  $N_w + N_s = 1$ , then

$$\frac{N_w}{N_s} = \frac{N_w}{1 - N_w} = \frac{a_w}{1 - a_w} \quad (2)$$

The moles of water which disappear from solution for each mole of sucrose, or the average degree of hydration of the sucrose, is obtained by subtracting (2) from (1).

For the case with association there is a little greater complexity. From the laws of semi-ideal solutions we have directly,

$$N_1 = N_0 a_w. \quad (3)$$

If the association follows the law of mass action in molar fractions,

$$N_2 = K N_1^2 = K N_0^2 a_w^2 = (1 - N_0) a_w^2. \quad (4)$$

The replacement of  $K N_0^2$  by  $(1 - N_0)$  is arrived at by solving the equation for the special case of pure water, for which  $N_2 = 1 - N_0$  and  $a_w = 1$ . The molar fraction of the sugar is equal to  $1 - N_1 - N_2$ . The quantity of water, calculated as moles of monohydrol, existing in solution per mole of sugar will be:

$$\frac{N_1 + 2N_2}{N_s} = \frac{N_1 + 2N_2}{1 - N_1 - N_2} \quad (5)$$

The average degree of hydration is obtained by subtracting (5) from (1).

### The Measurements of Activity.

For these calculations it is desirable to have as many and as accurate measurements of the vapor pressure as possible. In a concluding note Berkeley remarks that the 30° values are slightly in error due to a small

<sup>12</sup> J. J. van Laar, *Z. physik. Chem.*, 31, 1 (1897).

temperature gradient in the apparatus, and he records a few measurements with one apparatus where this error was corrected. In order to get the best values for all concentrations, a study was made of the difference between these corrected results and the uncorrected ones for each apparatus. This included the measurements on  $\alpha$ -methyl glucose and sulfuric acid. It was found that the average correction in the quantity  $-\ln a_w$  was, within the experimental error, independent of the concentration and of the apparatus and equal to 0.00023. So this correction was added to all the uncorrected results, and the best value was taken as the average of these values with those of the note, each weighted proportionally to the number of observations which it represents. Table I gives the best illus-

association of the water is to increase the calculated value of the average hydration by about 4/10 of a molecule, and that the increase is nearly independent of the concentration and temperature. The average degree

of hydration decreases from about 6 to 3.5, and it is smaller at  $40^\circ$  than at  $0^\circ$  as might have been expected. This agrees with the conclusions of Frazer and Myrick from the osmotic pressure. The decreasing values for the more dilute solutions at  $30^\circ$  may be attributed to experimental error, for in the most dilute solutions an error corresponding to the correction made in Table I makes a difference of about 0.5 molecule in average hydration. This same explanation accounts for the results of Jones and Getman and of Porter on dilute solutions. Both find considerably larger values for dilute solutions; while Bousefield finds from the freezing-point measurements of Morse and Frazer that the values are irregular but always less than 6. This means that values of the average degree of hydration calculated for solutions more dilute than  $C=20$ , at least from any measurements yet recorded, are of little value.

Fig. 1.—Average degree of hydration of sucrose.

#### SYMBOLS.

Full line: from vapor pressure at  $0^\circ$ , without association.

Dotted line: from vapor pressure at  $30^\circ$ , without association.

Triangles: from freezing point, Jones and Getman.

Inverted triangles: from freezing point, Jones and Getman, calculated by Scatchard.

Circles: from freezing point, Morse and Frazer, calculated by Bousefield.

Squares: from osmotic pressure at  $0^\circ$ , Berkeley, *et al.*, calculated by Porter.

Crosses: from solubility of hydrogen at  $18^\circ$ , calculated by Philip.

Fig. 1 contains some of the more interesting determinations of the average degree of hydration. The abscissas are concentrations (g. of sucrose per 100 g. of water), and the ordinates are the average degrees of hydration (molecules water for each molecule of sucrose). The values for the vapor-pressure determinations assuming association of the water are omitted as they give lines parallel to those assuming no association and would only

confuse the figure. Also, the figure does not extend to the most concentrated solutions for which the vapor pressures were measured. The increase of the hydration with increasing concentration found by Jones and Getman is seen to be due to the inaccuracy for concentrated solutions of their method of calculation. Their results as calculated by the author by the more accurate formula of Callendar<sup>13</sup> decrease regularly when they pass the concentration where the experimental error is very large. All the methods appear to agree within their respective experimental errors, which are not large for the concentrated solutions.<sup>14</sup>

### The Nature of the Hydrate.

We have already noted that the field of force of the sugar molecule is nearly uniform along its length. If there is a tendency for a water molecule to attach itself to one point in such a molecule, there should be a nearly

<sup>13</sup> Reference 2. p. 487, Formula VI.

<sup>14</sup> *Note added November 2.*—In the July number of *THIS JOURNAL* (43, 1391–6 (1921)), Kendall, comes to the very interesting and important conclusion that, for sufficiently dilute solutions, the degree of association of the water does not affect the vapor-pressure measurements, and that it may be neglected in calculating the degree of hydration of the solute from the colligative properties.

The present paper gives an interesting supplement to his conclusions in showing the magnitude of the effect for solutions which are not ordinarily considered as dilute. The weight-molar concentration varies from 1 *M* to 7 *M*. Since the calculations from the data on hand are relatively simple, the average degree of hydration was also calculated with the assumption that  $N_0 = 0.01$  and 0.001, that is that in pure water only one molecule in every hundred and in every thousand, respectively, is monohydrol, while the others are dihydrol. The two calculations agree within 0.01 molecule in every case, so that only those for  $N_0 = 0.001$  are tabulated. The differences between these values and those for  $N_0 = 1.0$ , or for no association, (from Table II) are also given.

TABLE II A.  
AVERAGE DEGREE OF HYDRATION OF SUCROSE, ASSUMING  $N_0 = 0.001$ .

Conc.	Av. hydrat.	0°.		30°.	
		Diff. from no. Assoc.		Av. hydrat.	Diff. from no. Assoc.

217.5	4.14	0.45		3.98	0.45
243.0	3.91	0.45		....	....

In this concentration range, these widely different assumptions make a difference of approximately one-half molecule in the average hydration. Comparison with Fig. 1 will indicate the unimportance of this compared to the experimental error in dilute solutions. Whether this factor need be considered in any case depends, of course, upon the accuracy of the results desired and justified by the experimental accuracy and the validity of the laws of semi-ideality for the case in question.

equal tendency toward attachment at several other points. Probably the addition of a water molecule at one point will not change the field or tendency to hydrate at other points. Then that hydrate in which all the equivalent positions are filled ought to be very much more stable than any of the lower hydrates. This hydrate will also have a nearly uniform field and may have a tendency to hydrate further. If so there will be another higher hydrate, existing in smaller quantities than the first, but larger than any of the other hydrates.

We will assume that there is one such hydrate of so great a relative stability that the quantities of all the other hydrates are negligibly small, and that the whole system can be considered as an equilibrium between water, anhydrous sugar and this hydrate. If the solution is semi-ideal the formation of this hydrate will obey the law of mass action in terms of molar fractions. By application of the law we can determine how well the assumption of any hydrate will explain the experimental facts.

It must be emphasized that this theory of one rather complex hydrate is not applied to hydration in solution in general, but is limited to carbohydrates, whose large uniform molecules should give them very special properties. This explanation of a varying average degree of hydration is believed to be original; and, although the literature contains many statements that hydrate formation obeys the law of mass action, there seems to have been no previous attempt to test with the experimental results.

Consider first the case in which the water is not associated. The law of mass action for the reaction  $C_{12}H_{22}O_{11} + mH_2O \rightleftharpoons C_{12}H_{22}O_{11} \cdot mH_2O$  will be

$$\frac{N_{hyd}}{N_{anh} \times (N_w)^m} = K_m. \quad (6)$$

We know  $N_w/N_s$  and the average degree of hydration. Since  $N_w + N_s = 1$ ,

$$1 + \frac{N_w}{N_s} = \frac{1}{N_s}.$$

The average degree of hydration divided by  $m$  will be

$$\frac{N_{hyd}}{N_s}, \text{ and } 1 - \frac{N_{hyd}}{N_s} = \frac{N_{anh}}{N_s}.$$

From these ratios the calculation of the molar fractions and of  $K$  is direct and simple.

For the case in which the water is associated, we have already determined  $N_1$ , which must replace  $N_w$  in the formula, and  $N_s$  in calculating the average degree of hydration. Dividing this average degree of hydration by  $m$  and multiplying by  $N_s$  will give  $N_{hyd}$ , and  $N_{anh} = N_s - N_{hyd}$ . This gives us all the data necessary for calculating  $K_m$  by Equation 6. Table III contains the values of  $K$  for  $m=6$  and  $m=7$ . The choice must lie between these two, for the values of  $K_s$  decrease too rapidly to be possible

and  $K_6$  leads to absurd results. The values of  $K_6$  are very good for the most concentrated solutions, but they increase rapidly with dilution for the more dilute; the values for  $K_7$  are fair throughout. At 30° either gives good constancy. The results for the dilute solutions are much less important, for there a small error in the vapor pressure corresponds to a large change in  $K$ . To illustrate this and to give a better test of the agreement of the theory with experiment, calculations are given in Table IV of the values of the vapor pressure which give constant values of  $K$  for the case without association.

These calculations have to be made by trial and error and are rather tedious. The values selected for the constants are approximately those which give the smallest deviations from the experimental results, but the choice may be more fortunate in one case than in another. So the results for  $K_6$  and  $K_7$  must not be compared too closely. At 0°, however, the heptahydrate clearly gives much better agreement. The table shows the enormous effect in  $K$  of a small error in the vapor-pressure measurements for the dilute solutions.

### The Activity of the Sucrose.

It is possible to attack the constitution of the hydrate from another

point of view. By the use of Lewis and Randall's modification<sup>15</sup> of the Duhem-Margules equation for the dependence of the activity of one component upon that of the other, it is possible to calculate the change in the activity of the sucrose with changing concentration. The method of calculation is to plot  $\log(a_w/N'_w)$  against  $N'_w/N'_{anh}$  (abscissa) and to measure the area under the curve between the concentrations chosen. This gives the change in  $\log(a_{anh}/N'_{anh})$  for it is the anhydrous sugar which is added to the solution. If our theory is correct  $a_{anh}/N'_{anh} = N_{anh}/N'_{anh}$ . With solutions of such strength as we are using it is unsafe to extrapolate in either direction. The simplest method is to make the comparison directly between the change in  $\log(a_{anh}/N'_{anh})$  and that in  $\log(N_{anh}/N'_{anh})$  as calculated according to the various assumptions. Since the values of the latter quantity are more accurate for the higher concentrations, the change is calculated from the highest concentration.

Table V gives the values of  $N'_w/N'_{anh}$ ,  $\log(a_w/N'_w)$  and the increase of  $\log(a_{anh}/N'_{anh})$  at 0° and at 30°. Table VI gives the values of the change in  $\log(N_{anh}/N'_{anh})$  as calculated according to the different assumptions and the differences between these values and the observed

changes in  $\log(a_{\text{anh}}/N'_{\text{anh}})$ . Again the values for the more concentrated solutions agree better for the hexahydrate, while over the greater part of the range they fit the heptahydrate better. And again, for the more concentrated solutions, there is a variation in the opposite direction for these two hydrates, showing that higher or lower hydrates would give poorer agreement.

These results are important as showing that the activity of the sucrose varies approximately as it should if our theories are correct. They confirm the idea that a varying proportion of the sugar exists in the unhydrated condition. As a test between the different assumptions, however, they are not entirely independent of the calculations of the equilibrium constants. If we use the vapor pressures which give constant values of  $K_s$ , the variation in  $\log(a_{\text{anh}}/N'_{\text{anh}})$  will agree exactly with that of  $\log N_{\text{anh}}/N'_{\text{anh}}$ , and similarly for the heptahydrate.

### Interpretation of the Results.

The vapor-pressure measurements do not agree within their apparent experimental error with the existence of either a hexahydrate or a heptahydrate alone, and our results seem to indicate that no assumption concerning the association of the water will better the agreement. It is possible that there is a constant experimental error in the vapor-pressure measurements which is larger than the agreement of the individual experiments indicates. An error of 0.1% at 30° and of 0.2–0.3% at 0° would account for the variation either for the hexahydrate or for the heptahydrate, depending upon the direction of the deviation. This is, however, from 5 to 10 times the apparent experimental error.

There seem to be three other possible explanations. First, our solutions may not be strictly semi-ideal, and the deviation from proportionality between the activities and the molar fractions might explain the results for either the hexahydrate or the heptahydrate, depending again upon the direction of the deviation. Second, our assumption of one hydrate so much more stable than the others may be entirely wrong, and the solution may contain an equilibrium mixture of a large number of hydrates in nearly equal quantities. Third, our assumption of one hydrate may be

only slightly in error, and there may be but one higher hydrate as suggested earlier in this paper. If so the predominating hydrate must be the hexahydrate or possibly an even lower one. If a hexahydrate, the agreement of the concentrated solutions would be due to the fact that the second hydrate would exist only in very small quantities in these solutions. The increasing quantities on dilution would account for the increase of  $K$  when calculated for the hexahydrate alone. Doubtless, given an arbitrary choice of the composition of this hydrate and its constant of dissociation, it would be possible to fit the experimental results within their error of measurement. But the formula would involve four arbitrary constants, and its agreement would not give a very strong confirmation of the theory. At  $30^\circ$  this higher hydrate would exist in much smaller quantities than at  $0^\circ$ .

**Evidence from other Sources.**—The surest proof of the existence of a compound in solution is its separation as a solid phase, identified by analysis or by the freezing-point curve. Guthrie<sup>16</sup> mentions a cryohydrate separating at  $-8.5^\circ$  with a composition of 5.27 mole per cent. (51.4%) sugar. This is far off the curve for anhydrous sugar and, if it were real, would indicate a hydrate. However, the ice curve drawn from Guthrie's other measurements will not pass through this point without sharp curvature. Jones and Getman obtained a smooth curve up to a concentration of 6.43 mole per cent. which freezes at  $-9.13^\circ$ . The author has made preliminary measurements extending to 8 mole per cent. where the freezing point is about  $-13^\circ$ . This extends the ice curve slightly beyond the sugar-solubility curve. In no case did anything but ice separate and the curve seems entirely regular. The fact that only ice separated in these experiments does not prove, of course, that the system ice: solution is not a metastable one from which a hydrate might be separated. The study of the freezing-point curve will be continued, and will at least extend the ice curve to meet that of sugar. So the present evidence from the phase rule means nothing. The molar fraction of the hydrate is small even at its highest concentration, and it should be so similar in polarity to the other components of the solution that it ought to be quite soluble. Then failure to isolate a solid hydrate would not be unexpected.

All of the physical properties of sucrose solution which have been measured seem to obey the additive law so closely that they give no indication except that there is a slight variation from ideality, but not necessarily from semi-ideality.

If the degree of association of water were accurately fixed, some insight could probably be gained from the heat of dilution of sucrose solutions. But the heat of reaction calculated from the change in the equilibrium constant with the temperature would depend very largely upon the assumption as to the degree of ionization of the water. There would also

<sup>16</sup> F. Guthrie, *Phil. Mag.*, [5] 2, 216 (1876).

be the accompanying reaction of the association of the water with a large thermal effect.

The only evidence other than that from the colligative properties seems to be that from the speed of inversion. It has been shown in the preceding paper that probably 6, but possibly 5 or 7 water molecules enter into the reaction with each sugar molecule, and that the most probable explanation is a preliminary hydration of the sugar molecule. The assumptions underlying the speed of inversion method are almost entirely different from those of the present paper. It is true that the assumption of semi-ideal solution was made in changing from activity of sucrose to molar fraction. Also the justifiability of that assumption is confirmed by its success in accounting for the variation of hydrogen-ion activity on the addition of sugar. Our only other assumptions, except for small correcting terms which might have been neglected, are that the speed of reaction in solutions is proportional to the activities of the reactants, and that the activity of the hydrogen ion which determines its catalytic effect is the same as that which determines the electromotive-force measurements.

The determination from the vapor pressures assumes that the solutions are semi-ideal, and that there is one hydrate which is very much more stable than the others. The hypothesis that the formation of the hydrate obeys the law of mass action in terms of molar fractions follows as a thermodynamic necessity from the assumption of semi-ideality. We have two independent methods which lead us to the conclusion that aqueous sugar solutions are equilibrium mixtures of sucrose, water and a hydrate of sucrose containing probably 6 molecules of water. There appears to be no evidence which contradicts this conclusion.

### Summary.

1. The average degree of hydration of sucrose in water solution at  $0^{\circ}$  and at  $30^{\circ}$  is calculated from the vapor pressures.
2. The theory is advanced that sucrose solutions are equilibrium mixtures of water, unhydrated sucrose and a single hydrate, and that the relative quantities of these substances are determined by the law of mass action.
3. This theory is tested by comparison of the experimental results with those calculated from the law of mass action. The agreement is fair for either a hexahydrate or a heptahydrate. The theory is also tested by a comparison of the activity of the sucrose calculated from its degree of hydration and that calculated by the Duhem-Margules equation. The results confirm those obtained by use of the law of mass action method.
4. The results agree with those obtained from the inversion of sucrose in the preceding paper.

## NOTE.

**The Precipitation of Arsenic Sulfide from Arsenates.**—The precipitation of arsenic sulfide from acid solutions of arsenates by hydrogen sulfide may be greatly hastened by the presence of a soluble iodide. This catalytic effect is doubtless due to the reduction of the arsenic acid to arsenious acid by the hydriodic acid, the iodine being continuously reconverted to hydriodic acid by the hydrogen sulfide.

The arsenious acid yields arsenic trisulfide readily, particularly in the presence of free hydrochloric acid. The assumed reduction of the arsenate to arsenite is confirmed by analysis of the precipitate, which is found to be mainly arsenic trisulfide and sulfur, with varying amounts of the pentasulfide.

This has been applied in the work in qualitative analysis at the University of Illinois in the following way. Just before passing in the hydrogen sulfide, 1 or 2 cc. of 1.0 *N* ammonium iodide solution (potassium or sodium iodide would vitiate subsequent tests for these cations) is added to the hot solution, which contains 4 cc. of 6 *N* hydrochloric acid in a volume of 40 cc. Precipitation begins immediately, and is usually complete in 4 or 5 minutes, depending on concentrations, temperature, agitation and so forth. Not only is the time for complete precipitation of pentavalent arsenic shortened to approximately  $\frac{1}{3}$  of that usually required, but the chances are much lessened that the student will fail to detect arsenic because of non-precipitation at this point.

Apparent complications arise in the precipitation of mercury and copper as iodides and in the partial reduction of the former to the mercurous state. However, these effects are rectified during the digestion with ammonium polysulfide, which oxidizes both metals to the higher valence, precipitating them as mercuric and cupric sulfides.

LABORATORY PREPARATION OF ACETALDEHYDE.<sup>1</sup>

BY CHESTER E. ADAMS WITH ROGER J. WILLIAMS.

Received July 7, 1921.

None of the laboratory methods for the preparation of acetaldehyde by the oxidation of alcohol is highly satisfactory, as the yields are low and uncertain. Gattermann's method<sup>2</sup> is recommended by Beilstein but the yield of aldehyde-ammonia at best is only about 23% of the calculated. In ordinary practice the yields are considerably lower than this. Noyes<sup>3</sup> predicts a yield of about 15% for the method outlined.

Preliminary work proved the unsatisfactoriness of the methods. If the oxidizing mixture used oxidizes the aldehyde more readily than alcohol (found by experiment to be true) then the production of aldehyde even in small amounts must be due to its low boiling point and its ability to escape from the mixture before oxidation takes place.

With this idea as a working basis several methods were used to increase the volatilization of the aldehyde, and the use of a mechanical stirrer was the only method found practicable. By this means yields were obtained more than double any obtained previously. That the stirring was responsible for the increase was proved by using the same procedure and apparatus except that the stirring was omitted, in which case the yield was very low.

Working with essentially the same apparatus and method, different concentrations of oxidizing agent were then tried to determine whether under these conditions better results could be obtained with some other concentration than that recommended by Gattermann.

The figures show that the amount of sodium dichromate recommended by Gattermann (200 g. per 100 g. of alcohol) could not be materially im-

<sup>3</sup> Noyes, "Organic Chemistry for the Laboratory," 1911, p. 89.

proved upon. Not only are the yields much better than those obtainable formerly, but practically the same results can be obtained repeatedly by using the method. The amounts of alcohol varied in the different experiments because it was forced into the reaction flask by air pressure through a capillary tube and the amount used was determined by difference. The capillary tube was found a convenient means of introducing the alcohol in a steady stream, but a dropping funnel can be used successfully. The method which proved most successful is outlined below.

### Method.

A 1-liter flask is fitted with a 3-holed stopper carrying a reflux condenser tube of good length and placed at an angle for refluxing, a dropping funnel (or capillary tube through which liquid can be forced), and an electrically-driven stirrer provided with a mercury seal. The mercury seal is used to prevent loss of aldehyde through the opening, and in our experiments was of the same type as the water seal recommended by Fischer for a similar purpose.<sup>4</sup> Through the condenser is passed a current of water at about 25°. The upper end of the condenser is fitted with a delivery tube of good size dipping into a small wide-mouthed flask containing about 80 cc. of well-dried ether. This flask is in turn connected with a second similar flask containing about 30 cc. of ether to absorb any aldehyde passing over. One hundred and ten g. of conc. sulfuric acid in 200 cc. of water is put into the flask and the stirrer adjusted. The solution is then heated to about the boiling point. A mixture of 50 g. of alcohol (95%) 100 g. of sodium dichromate and 100 cc. of water is then introduced slowly through the capillary or the dropping funnel, with mechanical stirring. With a small flame under the flask the alcohol is admitted as fast as allowed by complete absorption in the ether and sufficient cooling in the condenser. When the alcohol is all admitted the reaction mixture is stirred for a few minutes as long as aldehyde appears to come over. The ether solution is then saturated with dry ammonia in the usual way and allowed to stand overnight when the crystals of aldehyde-ammonia are filtered off, pressed dry, freed from remaining ether and weighed. For the preparation of purer aldehyde-ammonia probably a preliminary distillation such as recommended by Gattermann should be made before the aldehyde is collected in the ether.

### Summary.

A study of the oxidation of alcohol to aldehyde by sodium dichromate showed that the introduction of a mechanical stirrer to disengage the aldehyde as fast as it is formed, increases the yield of aldehyde-ammonia at least 100% and gives consistent results. The method used is outlined.

 REARRANGEMENTS OF SOME NEW HYDROXAMIC ACIDS RE-  
 LATED TO HETEROCYCLIC ACIDS AND TO DIPHENYL- AND  
 TRIPHENYL-ACETIC ACIDS.<sup>1</sup>

By LAUDER W. JONES AND CHARLES D. HURD.

Received July 11, 1921.

A summary of the serious attempts to explain the mechanism of the Beckmann rearrangement must necessarily include the work of Hoogewerff and van Dorp,<sup>2</sup> Hantzsch,<sup>3</sup> Stieglitz,<sup>4</sup> and Jones.<sup>5,6</sup> The types of compounds generally assumed to undergo this rearrangement are the azides, mono-substituted  $\beta$ -hydroxylamines, monobromo-amines, oximes, amidoximes, oximido acid esters, acid halogen amides and the hydroxamic-acid derivatives. The azides are assumed to decompose as follows:

These two cases, together with the mono-substituted  $\beta$ -hydroxylamines presented below, furnish examples of the Beckmann rearrangement that have never been explained successfully except by the theory of Stieglitz and of Jones.

Stieglitz was the first investigator to propose the hypothesis that univalent nitrogen derivatives form the primary decomposition products in these rearrangements. His extensive experimental work has demonstrated the soundness of this postulate.<sup>7</sup> Some years later, Jones formulated the reaction mechanism in a detailed manner by applying the theory of electron valence to the interpretation given by Stieglitz. The electron mechanism was represented as follows.<sup>5,6</sup>

Unless there were a driving force acting to cause the transfer of the radical from carbon to nitrogen, it would still be difficult to imagine why the

<sup>7</sup> The rearrangement of ketoximes, which was originally attributed by Stieglitz to the formation of univalent nitrogen derivatives, is now regarded as an exception. His present view assumes "the rearranging power of an intermediate hydrochloride of a univalent nitrogen derivative, acting in place of the ordinary free univalent nitrogen compound." See Montagne (*Ber.*, **43**, 2015 (1910)), Schroeter (*ibid.*, **44**, 1207 (1911)), and Stieglitz.

reaction should proceed, even with the explanation offered. Such a driving force is to be found in the shifting of electrons within the molecule. Jones stressed particularly that the free valences of univalent nitrogen afforded the "stage setting required to furnish a suitable environment in which the essential action," *viz.*, the transfer of the radical from carbon to nitrogen might take place. In a footnote to an article published some months later,<sup>4</sup> Stieglitz stated that, in regard to the most fundamental questions of these rearrangements "postulating a shifting of electrons from carbon to nitrogen, and a migration of a positive radical, Professor Jones and the writer are happily in entire agreement."

As viewed from present day standards, this interpretation with very slight modifications, still holds. In late years, worthy evidence<sup>5</sup> has been submitted to show that the positive charges possessed by an atom are centered in its nucleus. In compounds which are formed by the sharing of negative electrons, a "bond" consists of a pair of electrons held in common between two atoms. This theory of a chemical bond requires symbols in which positive charges cease to appear, except as they form an integral part of the nucleus of any atom. Such an interpretation would mean simply that a symbol,  $C^+ \vdash N$ , employed at a time when ion charges, rather than electrons in the present sense, held the attention of chemists, would now become  $C : N$ ; that is, the carbon atom and the nitrogen atom share a single pair of electrons. This conception of paired electrons would account just as readily for the driving force necessary to bring about rearrangement. Thus, the system of symbols  $C : N \rightarrow C \vdash N$  is equivalent to  $C^+ \vdash N \rightarrow C \vdash N$  previously employed.

Possibly the formula  $C \vdash N$  contains an assumption not necessarily implied by the formula  $C : N$  in which two pairs of electrons are shared, since the former suggests that a compound which contains such a group would not be exactly non-polar, although it should not be regarded as polar in the sense in which  $Na^+ Cl^-$  must be. To meet difficulties of this kind, Lewis employs formulas in which the pairs of electrons are placed nearer one symbol than another, *e. g.*,  $A : B$ , which implies that the molecule  $AB$  shows some polar characteristics. With these modifications to adapt the old electronic formulas to present day practices, equations may be given to represent the rearrangement of a univalent nitrogen derivative of a hydroxamic acid.

Formulas I, Ia and Ib represent the intermediate univalent nitrogen derivative; Formulas II, IIa and IIb represent a transition stage, the rearrangement of the positive radical, R. It will be noted that, in Formula II, although the carbon atom still has its "octet" completed, the nitrogen atom has only 6 electrons in the outer shell. By the sharing of electrons, both the nitrogen and the carbon atoms may complete their octets. This

Fig. 1.

Fig. 2.

is represented in Formulas III, IIIa and IIIb, the isocyanate stage in the rearrangement.

With this conception, it is easy to understand why the radical R is able to part company with carbon and attach itself to nitrogen. No hypothesis has been offered, however, to explain why one radical R will do so with much greater readiness than some other radical R'. To seek an explanation of this factor was one of the motives that prompted the work which follows.

Chief interest in the present paper centers upon the reactions of dihydroxamic acids. They have been shown to rearrange in the following manner.

Either the action of heat, or of warm solutions of alkalis, will produce this effect. In the former case, the isocyanate is formed by dry distillation of the dihydroxamic acid, or, preferably, by heating a salt of the acid. Usually there is a fairly definite temperature at which the decomposition of the dry salt takes place. However, certain cases have proved that it is not a reliable method to use when two similar compounds are to be judged for comparative ease of rearrangement. If solutions are employed, the isocyanate generally reacts immediately with water to form the amine, or the corresponding disubstituted urea. The behavior of neutral solutions

of the sodium or of the potassium salts in water seems now to furnish a more accurate criterion by which to judge the ease of rearrangement of these particular compounds

A few years ago, phenyl-acethydroxamic acid<sup>9</sup> was studied. The benzoyl ester of this acid was capable of forming salts which possessed unusual instability towards heat. Its solid potassium salt suffered Beckmann rearrangement spontaneously at room temperature. Here,

Because of this rearrangement, it was not found possible to form a clear solution of the salt in water, unless it was prepared immediately after the isolation of the salt. We have recently repeated this experiment, and found, in addition, that the clear solution, when left at room temperature for 2 hours, did not undergo a noticeable rearrangement. A small white precipitate of the urea collected in 10 hours, however. The similar potassium salt of the benzoyl ester of acethydroxamic acid,  $\text{CH}_3-\text{CO}-\text{NK}-\text{OCOC}_6\text{H}_5$ , did not possess this marked tendency to rearrange; so the replacement of hydrogen by phenyl must have occasioned the decrease in stability. With this in view, diphenyl- and triphenyl-acethydroxamic acid were deemed important compounds to study. The sodium or the potassium salts of their acyl esters should exhibit a greater capacity for rearrangement in solution than the similar compounds in the monophenyl series.

The univalent nitrogen compounds,  $[\text{R}-\text{CO}-\text{N}]$ , which have been assumed to be the primary products of decomposition, have never been isolated. The isocyanates, resulting from rearrangements which involve readjustments of electrons, are obtained instead. It was not our object in this investigation to try to isolate such derivatives. Indeed, with the groupings  $[(\text{C}_6\text{H}_5)_2\text{CH}-\text{CO}-\text{N}]$ , and  $[(\text{C}_6\text{H}_5)_3\text{C}-\text{CO}-\text{N}]$  the tendency to rearrange to form isocyanates should be greater than in any case previously studied.

Triphenylmethyl is a group that is known to display a tendency to exist as a free radical. Certainly, then, it would seem highly probable that a derivative such as  $[(\text{C}_6\text{H}_5)_3\text{C}-\text{CO}-\text{N}]$ , would be far more apt to separate momentarily into  $[(\text{C}_6\text{H}_5)_3\text{C}-]$  and  $[-\text{CO}-\text{N}]$  than a group such as  $[\text{H}_3\text{C}-\text{CO}-\text{N}]$  in which the linking of carbon to carbon is conceived to be stronger. The latter would give rise to  $[\text{H}_3\text{C}-]$  and  $[-\text{CO}-\text{N}]$ . By no means must it be considered probable that free radicals displaying the great order of reactivity shown by triphenylmethyl could ever be isolated while in the presence of the highly reactive univalent nitrogen.

As a result of earlier experiments, and of those included in this article,

<sup>9</sup> Thiele and Pickard, *Ann.*, 309, 189 (1899); Jones, *Am. Chem. J.*, 43, 6 (1912).

we were led to formulate an hypothesis which may be stated as follows: the relative ease of rearrangements of the Beckmann type is dependent upon the tendency for the radical R, in the univalent nitrogen derivative, *e. g.*, [R—CO—N], to exist as a free radical.

It must be noted that this hypothesis does not deal with the ease of formation of the univalent nitrogen compound. It is essential that the group —NHX in the original molecules, R—CO—NHX, be identical when two different compounds are compared. An extreme case of the effect produced when different groups are substituted is displayed in the acyl alkyl halogen amines, *e. g.*, R—CO—NCl—C<sub>6</sub>H<sub>11</sub>. Stieglitz observed that compounds of this type show no tendency to undergo rearrangement.<sup>10</sup>

Triphenylmethyl, and other groups that are known to exist free, have been shown to exhibit polar characteristics in many of their compounds. For example, triphenylmethyl bromide displays marked conductivity when dissolved in sulfur dioxide;<sup>11</sup> this is one of the arguments which leads to the belief that an ion, or a pseudo-ion, (C<sub>6</sub>H<sub>5</sub>)<sub>3</sub>C<sup>+</sup>, must exist in the solution. Furthermore, it has been shown that triphenylmethyl is formed in the cathode chamber when triphenylmethyl bromide is electrolyzed. In fact, appropriate solutions of triphenylmethyl, itself, conduct the electric current.<sup>12</sup> These are important facts in support of our hypothesis.

From the standpoint of our hypothesis, it would seem that the tendency for the phenylmethyl radical, C<sub>6</sub>H<sub>5</sub>—CH<sub>2</sub>, to exist free is greater than for methyl, CH<sub>3</sub>. The allusion is to the experimental fact that the derivatives of phenyl-acethydroxamic acid suffer rearrangement more easily than those of acethydroxamic acid. On the basis of this hypothesis, also, the observation made by McCoy and Stieglitz,<sup>13</sup> and supplemented by van Dam,<sup>14</sup> that dibromo-salicylic-bromo-amide rearranges even at —12°, is evidence for the tendency of the radical C<sub>6</sub>H<sub>2</sub>Br<sub>2</sub>.OH to exist free. Other bromo-amides that have been studied exhibit a more stable character.

From this same standpoint, it may be predicted that any substituted acethydroxamic acid containing a tri-aryl methyl group will undergo rearrangement with great ease. For example, tri-bisphenyl-acethydroxamic acid, (C<sub>6</sub>H<sub>5</sub>—C<sub>6</sub>H<sub>4</sub>)<sub>3</sub>C—CO—NHOH, should form derivatives that are even more unstable than triphenyl-acethydroxamic acid. The group tribisphenylmethyl, in contrast to triphenylmethyl, is one that has been shown to exist exclusively in the monomolecular form at room

<sup>10</sup> Stieglitz, *Am. Chem. J.*, 29, 49 (1903).

<sup>13</sup> McCoy and Stieglitz, *Am. Chem. J.*, 21, 116 (1899).

<sup>14</sup> Van Dam, *Rec. trav. chim.*, 18, 408 (1899); 19, 318 (1900).

temperature.<sup>15</sup> Therefore, in the univalent nitrogen derivative,  $[(C_6H_5-C_6H_4)_2C-CO-N]$ , there should be a pronounced tendency for the momentary existence of tribisphenylmethyl, and the ultimate formation of the isocyanate.

The applications of this hypothesis need not be restricted to one class of radicals that show a tendency to exist free. Since certain radicals which contain divalent nitrogen<sup>16</sup> have been prepared, a hydroxamic acid which could furnish such a group might also rearrange with considerable ease. Illustrations would be,

Benzophenone when it is treated in ether solution with potassium develops an intense color.<sup>17</sup> Since the boiling point of the ether is unchanged after complete solution of the metal, a trivalent carbon radical,  $(C_6H_5)_2C(OK)-$ , is assumed to exist in solution. In this connection, therefore, the hydroxamic acid of benzilic acid,  $(C_6H_5)_2C(OH).CO.NHOH$ , should present a somewhat complicated, but, nevertheless, a highly interesting case to develop.<sup>18</sup>

Our assumptions were corroborated to a large extent by the experimental evidence submitted in this paper. Unexpected difficulties presented themselves in the attempts to prepare the sodium and potassium salts in the diphenyl-acethydroxamic acid series. If the customary procedure, *viz.*, the addition of an alcoholic solution of sodium ethylate to an alcohol-ether solution of the benzoyl ester of the acid, *e. g.*,  $(C_6H_5)_2CH-CO-NH-OCOC_6H_5$ , was followed, no precipitation of the salt occurred, even when a very large excess of ether was used. The existence of the salt in solution was proved, but the salt could not be obtained pure. Evaporation of the alcohol and ether *in vacuo* always left a mixture of the salt with its products of decomposition and rearrangement; *viz.*, diphenylmethyl isocyanate, diphenylmethyl urethane, sodium benzoate and, also, *sym.* bi-diphenylmethyl urea, if any water was present. When this residue was extracted with cold water, and the solution filtered and boiled, there was an immediate precipitation of some *sym.* bi-diphenylmethyl urea, which is the normal reaction for salts of this character.

Similar difficulties arose in the study of triphenyl-acethydroxamic acid. The sodium or the potassium salts of the benzoyl ester could not be formed pure. The acetyl ester seemed to yield a potassium

<sup>17</sup> Schlenk and Thal, *Ber.*, 46, 2843 (1913); Schlenk and Weichel, *ibid.*, 44, 1183 (1911).

<sup>18</sup> Jones and Neuffer (THIS JOURNAL, 39, 659 (1917)), have studied the rearrangements of lact-hydroxamic acid,  $CH_3-CHOH-CO-NHOH$ , and of mandel-hydroxamic acid,  $C_6H_5CH(OH).CO.NHOH$ .

salt insoluble in ether; but subsequent tests showed that it was mixed to a large extent with triphenylmethyl isocyanate. This isocyanate, not previously described, possesses a remarkable stability, even in the presence of boiling water. Thus, when the precipitate containing the potassium salt was taken up in water, and heated, only the isocyanate separated. The cause of its sluggishness may be attributed to its insolubility in water. It reacts normally with aniline in ether to form the urea derivative.

The evidence obtained proves that there is an increase in the ease of rearrangement of the molecule as more phenyl groups are added. In solution, the potassium salt of the benzoyl or acetyl ester of monophenyl-acethydroxamic acid was comparatively stable at room temperature; a similar solution of the diphenyl compound became turbid in a short time; whereas the triphenyl derivative showed rearrangement almost immediately when it was treated with water. In the diphenyl or in the triphenyl series, it was found to be impossible to obtain a sodium or a potassium salt which failed to show the effects of extensive decomposition. For this reason, the temperature of decomposition of the pure dry salts could not be determined accurately.

The silver salts, made by the action of aqueous silver nitrate upon the cold ether solutions of the sodium or potassium salts were somewhat soluble,<sup>19</sup> but precipitated for the most part. Chromo-isomerism was displayed here. The silver salt of the benzoyl ester of diphenyl-acethydroxamic acid, when first formed, was bright yellow. In a short time, the yellow substance changed to a pure white salt. The similar salt in the triphenyl series precipitated as a white solid, but changed soon to a brilliant yellow salt.<sup>20</sup>

<sup>19</sup> The exact cause of the solubility of the sodium and of the potassium salts in alcohol with a large excess of ether is purely a matter of conjecture. There may be tautomeric forms, one soluble and the other insoluble, such as  $(C_6H_5)_2CHC=O-NK-OCOCH_3$  and  $(C_6H_5)_2CH-C(OK):N-OCOCH_3$ . It may be caused by the addition of a molecule of alcohol; thus,  $(C_6H_5)_2CH-C(OK)(OC_2H_5)-NH-OCOCH_3$ . These are suggestions, which may be correct. Salts of the alkali metals which are soluble in ether are very uncommon but not unknown. Sodium iodide behaves in this manner. Loeb, *THIS JOURNAL*, 27, 1020 (1905).

<sup>20</sup> There are many chromo-isomers on record; such, for example, as silver violurate (Hantzsch, *Ber.*, 42, 969 (1909); Henrich, "Theorien der Org. Chem.," 1918, p. 364) which is colorless when precipitated, and gradually changes through green to a dark brown. Titherley (*J. Chem. Soc.*, 71, 468 (1897); 79, 408 (1901)), reported silver benzamide to exist in an orange and in a white modification. Jones and Oesper (*THIS JOURNAL*, 36, 2208 (1914)), found chromo-isomeric silver salts among acyl derivatives of hydroxy-urethanes; e. g.,  $C_6H_5CO-O-NaAg-CO-OR$ . These salts, yellow when prepared were easily transformed into white modifications, especially if R represents *iso*-butyl, *iso*-amyl, or benzyl.

Although the salts of the alkali metals could not be isolated pure, solutions of them in water could be obtained without extensive decomposition, if the silver salts were suspended in an ice-cold solution of potassium bromide. In a few hours the reaction was complete. This constitutes a helpful modification of a reaction never before applied to hydroxamic acids.

An interesting relationship between chemical constitution and melting points is to be gained from a study of the following table. The low melting benzoyl ester of triphenyl-acethydroxamic acid is of particular interest (See experimental part, p. 2439.)

	M. Pt. °C.	Benzoyl ester. °C.	Difference. °C.
CH <sub>3</sub> CO—NHOH	87	69 or 98	18 or +11
C <sub>6</sub> H <sub>5</sub> CH <sub>2</sub> CO—NHOH	145	120	25
(C <sub>6</sub> H <sub>5</sub> ) <sub>2</sub> CH—CO—NHOH	173	140	33
(C <sub>6</sub> H <sub>5</sub> ) <sub>3</sub> C—CO—NHOH	178	44–47	131–134

Two new methods of preparation of hydroxamic acids were investigated. First, the action of free hydroxylamine upon a ketene. With diphenyl ketene, the compound formed was diphenyl-acethydroxamic acid, the same in every respect as that prepared by other means. The equation is

The reaction is perfectly analogous to the addition of ammonia, or amines, to ketenes,  $R_2C:CO + H-NHR' \longrightarrow R_2CH-CO-NHR'$ . Staudinger<sup>21</sup> predicted the formation of hydroxamic acids, but stated "Die Einwirkung von Hydroxylamine, die zur Bildung von Hydroxamsäuren führen sollte, ist noch nicht untersucht."

There is another possible direction in which hydroxylamine might add to diphenyl ketene. The amide of benzoic acid would be formed;  $(C_6H_5)_2C:CO + NH_2OH \longrightarrow (C_6H_5)_2C(OH)-CONH_2$ . There are no cases recorded in which the hydroxyl group adds to ketenes in such a manner. Invariably, it combines with the carbonyl group. Hydrogen peroxide, similar in many respects to hydroxylamine, would be forced to add hydroxyl and form benzoic acid, if there were addition at all. However, Nicolet and Pelc<sup>22</sup> recently reported that the amount of benzoic acid formed when the two were mixed in anhydrous solvents was no greater "than when the ketene itself, without the addition of peroxide was treated in the same way." In the light of these results, it is not at all surprising that no trace of the amide of benzoic acid was found.

A profitable field of research is made possible by this reaction. For example, such ketenes as diphenylene ketene,  $(C_{12}H_8):C:CO$ ; methyl

<sup>21</sup> Staudinger, "Die Ketene," F. Enke, Stuttgart, 1912, p. 36.

<sup>22</sup> Nicolet and Pelc, *THIS JOURNAL*, 43, 935 (1921).

vinyl ketene,  $\text{CH}_2 : \text{CH}-\text{C}(\text{CH}_3) : \text{CO}$ ; ethyl ketene carboxylic ester,  $\text{OC} : \text{C}(\text{C}_2\text{H}_5)-\text{COOC}_2\text{H}_5$ ; carbon suboxide,  $\text{C}_3\text{O}_2$ ; and ketene, itself, with hydroxylamine, or substituted hydroxylamines, should lead to interesting results.

The second new method of preparing hydroxamic acids is a modification of the long established method in which acid chlorides are employed. Heretofore, the chloride has been allowed to act upon an aqueous solution of hydroxylamine. This always leads to side reactions, which lower the yield and augment the difficulty of purification of the desired product. When the acid chloride was dissolved in a neutral solvent, such as benzene, and a trifle more than 2 mols of free hydroxylamine was added, it was found that a quantitative yield of monohydroxamic acid resulted.

This reaction was modified later so that the preparation of free hydroxylamine was avoided. Two equivalents of pyridine or of sodium carbonate crystals was used with one equivalent of hydroxylammonium chloride in a benzene or an ether solution of the acid chloride. A quantitative yield was obtained here also.

Two heterocyclic hydroxamic acids were studied, one a derivative of furane, and the other of thiophene. The former (I) will be called

pyromucyl-hydroxamic acid; and the latter (II),  $\alpha$ -thenhydroxamic acid.<sup>23</sup> Previous work with heterocyclic hydroxamic acids is very slight. Pyromucyl-hydroxamic acid was prepared by Pickard and Neville,<sup>24</sup> and by Rimini,<sup>25</sup> but was not extensively studied. A few isolated examples in the pyrone series are known.<sup>26</sup> *Anti*-ethyl-thenhydroximic acid,  $\text{C}_4\text{H}_5\text{S}-\text{C}(\text{OC}_2\text{H}_5) : \text{NOH}$ , has been studied by Douglas.<sup>27</sup> It was not found possible to isolate this in the *syn* form. One object of our investigation was to

<sup>23</sup> Other names such as  $\alpha$ -thienyl formhydroxamic acid, or  $\alpha$ -thenoyl- $\beta$ -hydroxylamine suggest themselves. Both of these names have their shortcomings. Essentially, the compound is a derivative of thiophene, not of formhydroxamic acid; to call it a "hydroxylamine," conceals the acid nature of the substance. The difficulty could be avoided easily, if thiophene- $\alpha$ -carboxylic acid possessed a simple name. It would be entirely in keeping with both its chemical and physical properties to assign it a name similar to benzoic acid. Inasmuch as the grouping "thenoyl,"  $\text{C}_4\text{H}_5\text{S}-\text{CO}-$  is in common usage already, the name *thenoic* acid is suggested. The prefix "then" corresponds to "benz," and just as  $\text{C}_6\text{H}_5-\text{CONHOH}$  is benzhydroxamic acid, so  $\text{C}_4\text{H}_5\text{S}-\text{CONHOH}$  is  $\alpha$ -thenhydroxamic acid.

<sup>27</sup> Douglas, *Ber.*, 25, 1312 (1892).

study the chemical behavior of pyromucyl-, and of thenhydroxamic acids, since they are typical members of a legion of unstudied heterocyclic compounds.

Pickard and Neville<sup>24</sup> stated "an aqueous solution of the sodium salt" of the benzoyl ester of pyromucyl-hydroxamic acid,  $C_4H_3O-CO-NNa-O-COC_6H_5$ , "when boiled with water evolves carbon dioxide and an oil (containing nitrogen) is obtained when the solution is evaporated. The oil is presumably difurfuran-carbamide, but decomposes completely when hydrolyzed. No better success was obtained on attempting to prepare the carbamates by boiling the sodium salt with alcohols."

A year later, Curtius and Leimbach<sup>28</sup> tried to isolate *sym.* difuryl urea,  $CO(NH-C_4H_3O)_2$ , from the azide,  $C_4H_3O-CO-N_3$ , and met with only partial success. Crystals melting at  $229^\circ$ , and at  $220^\circ$  were obtained. The former was found to contain 12.01% of nitrogen, the latter 12.13%. The calculated percentage for difuryl urea is 14.56%.

In the present study, it was found that when the potassium salt,  $C_4H_3O-CO-NK-OCOC_6H_5$ , was warmed gently in water solution, and cooled at the first evidence of precipitation, the precipitate formed was the free benzoyl ester,  $C_4H_3O-CO-NH-OCOC_6H_5$ . This compound is produced by hydrolysis, not by rearrangement. When this same filtrate was heated to boiling, much carbon dioxide was evolved, and a red resinous mass precipitated; after purification, it melted at about  $210^\circ$ . This material is similar to the product found by Curtius and Leimbach.

Thenhydroxamic acid derivatives were observed to undergo a slight hydrolysis also, but rearrangement to form *sym.* di-thienyl urea was a simple matter. Curtius and Thyssen<sup>29</sup> obtained this same urea from the azide,  $C_4H_3S-CO-N_3$ . The properties of their compound check with those of ours in all respects. The normal reaction, then, is as follows,

This behavior is entirely analogous to that of the salts of dibenzhydroxamic acid.

It will be noticed that the benzoyl ester of thenhydroxamic acid is isomeric with the thenoyl ester of benzhydroxamic acid. The latter compound was prepared, so that comparative properties of the two might be observed. Melting points of the pure substance, and the temperatures at which the potassium and the silver salts decomposed were for the former  $144^\circ$ ,  $125^\circ$  and  $168^\circ$ ; for the latter,  $133^\circ$ ,  $135^\circ$  and  $165^\circ$ , respectively. The ease of rearrangement of the potassium or the sodium salts in aqueous solution was nearly identical. Too much stress should not be laid upon the temperature of decomposition of the solid salts. The figures are of importance, but the method of applying heat to determine the temperature

<sup>28</sup> Curtius and Leimbach, *J. prakt. Chem.*, [2] 65, 37 (1902).

<sup>29</sup> Curtius and Thyssen, *ibid.*, [2] 65, 17 (1902).

of decomposition influences them very much. For example, when the potassium salt of the latter compound is heated slowly there is no visible action until about  $160^{\circ}$ . However, if the tube containing the salt is suddenly thrust in a bath at  $135^{\circ}$ , there is violent decomposition. With most of the salts, however, there is a fairly definite temperature at which they explode when heat is applied gradually.

The physical and some of the chemical properties of thiophene compounds are very similar to those of corresponding benzene compounds. Thenhydroxamic acid is no exception. It melts at  $124^{\circ}$ , while benzhydroxamic acid also melts at  $124^{\circ}$ . It is of interest to note that di-thenhydroxamic acid melts much lower than di-benzhydroxamic acid. The former was found to exist in two modifications, one melting at  $105\text{--}107^{\circ}$ , and the other at  $83\text{--}86^{\circ}$ . Dibenzhydroxamic acid is reported by Lossen<sup>30</sup> to melt at  $145^{\circ}$ . Both of these heterocyclic hydroxamic acids resemble benzhydroxamic acid in that they form an acid ammonium salt,<sup>31</sup>  $(R\text{--CO--NH--O})_2\text{--H.NH}_4$ , which is difficultly soluble in water.

### Experimental Part.

#### 1. Preparation of Diphenyl-acethydroxamic acid, $(C_6H_5)_2CH.CO.NHOH$ .

**First Method.** From Ethyl Diphenyl-acetate.—Thirty g. of ethyl diphenyl-acetate was dissolved in 180 cc. of methanol which contained a little more than the calculated amount of free hydroxylamine. The hydroxylamine was liberated from 15 g. of its hydrochloride by a solution of sodium methylate, which contained 4.8 g. of sodium. To this mixture a solution of 3.3 g. of sodium in 60 cc. of methanol was added. After 10 hours, the mixture was diluted with one liter of water, and the hydroxamic acid was precipitated with dil. sulfuric acid. The filtrate, separated from this precipitate, contained a little diphenyl-acethydroxamic acid. By the addition of a solution of copper acetate to this filtrate, 4 g. of the green copper salt was obtained.

A solution of sodium carbonate was used to purify the crude diphenyl-acethydroxamic acid, since it was found to dissolve all of the diphenyl-acetic acid present, but none of the hydroxamic acid. The insoluble part was removed and washed several times with water, and when dry, weighed 35 g. The crude material melted between  $145^{\circ}$  and  $158^{\circ}$ . Recrystallization from ethyl acetate formed needle-shaped crystals melting at  $172^{\circ}$ .

Diphenyl-acethydroxamic acid is soluble in acetone, in ethyl acetate, in ethyl alcohol, and in a warm solution of sodium hydroxide. It is insoluble in water, in a solution of sodium carbonate (hot), in ligroin, in benzene, in ether, or in chloroform. An alcoholic solution yields the characteristic red color with ferric chloride.

*Analyses.* Subs., 0.1470, 0.1589;  $CO_2$ , 0.3962, 0.4321;  $H_2O$ , 0.0767, 0.0852. Calc. for  $C_{14}H_{13}O_2N$ : C, 73.98; H, 5.77. Found: C, 73.53, 74.18; H, 5.84, 6.00.

Subs., 0.3042; N, 16.8 cc. ( $24^{\circ}$  and 743.3 mm. (17.5")) 30% KOH sol. used. Calc. N, 6.17. Found: 6.08.

Diphenyl-acethydroxamic acid could not be prepared in quantity by the action of ethyl diphenyl-acetate upon free hydroxylamine. Enough was formed to give a purple coloration with ferric chloride, but in order to obtain a satisfactory yield, one mol. of sodium methylate (or its equivalent) seemed essential.

<sup>30</sup> Lossen, *Ann.*, 161, 347 (1872).

<sup>31</sup> Lossen, *ibid.*, 281, 172 (1894).

**Second Method. From Diphenyl-acetyl Chloride.**—Diphenyl-acethydroxamic acid was also prepared from diphenyl-acetyl chloride, although the method was less satisfactory because of side reactions. A solution of 1.9 g. of hydroxylammonium chloride in a small amount of water, was mixed with a solution of 2.8 g. of sodium carbonate. After carbon dioxide had escaped, 6 g. of diphenyl-acetyl chloride crystals was added and the mixture was shaken vigorously. When the reaction had apparently ceased, the product was warmed to 60°, then filtered to collect the solid. When the filtrate was acidified, half a gram of diphenyl-acetic acid (m. p. 145°) precipitated.

The residue obtained by filtration (5 g.) gave a double melting point, 155–160°, and 215–230°. Recrystallization from ethyl acetate led to the separation of diphenyl-acethydroxamic acid (m. p. 172°), and *sym.* bi-diphenylmethyl urea (m. p. 269–270°),  $\text{CO}(\text{NH}.\text{CH}(\text{C}_6\text{H}_5)_2)_2$ , which will be described later. Yield of the hydroxamic acid, 2 to 3 g.

**Third Method. From Diphenyl Ketene.**—Diphenyl ketene was prepared by Schroe-

ter's method.<sup>32</sup> Azibenzil, formed by the oxidation of 29 g. of benzil hydrazone dissolved in 120 cc. of dry benzene, was warmed to 60° in a current of dry carbon dioxide for about 3 hours, until evolution of nitrogen had ceased.

Two g. of freshly distilled hydroxylamine was suspended in a mixture of 50 cc. of absolute ether and 20 cc. of ethyl acetate, which had been carefully purified to remove traces of alcohol, water, or acetic acid. To this mixture, 100 cc. of the benzene solution of diphenyl ketene was added, while air was excluded carefully by maintaining an atmosphere of dry hydrogen gas.<sup>33</sup> Ether was employed to increase the solubility of hydroxylamine, which is insoluble in benzene. A better yield would be obtained, no doubt, if an ether solution of diphenyl ketene were used, but in this preparation the yield was of secondary interest.

After the mixture had been shaken thoroughly, the product gradually darkened. From time to time, the stopper of the flask was lifted momentarily to release the pressure, probably caused by the decomposition of some hydroxylamine. After two hours, very little pressure accumulated; so the flask was left overnight. The solvent was then distilled at the temperature of a water-bath and the residue was poured into an Erlenmeyer flask to crystallize. The crystals secured in this way were crystallized from ethyl acetate and petroleum ether. Yield, 4 g. After one recrystallization, the melting point was 169–172°.

To establish the identity of this compound and diphenyl-acethydroxamic acid prepared above, the benzoyl esters of both were made and found to possess identical properties. Both preparations melted at 140°. (See below.)

**Fourth Method. From the Copper Salt.**—Apparently, there are two forms of mono-phenyl-acethydroxamic acid. By the decomposition of the copper salt with hydrogen sulfide, Thiele and Pickard<sup>9</sup> obtained a compound melting at 121°. Phenyl-acethydroxamic acid which melted at 145° was prepared by Jones by the interaction of free hydroxylamine and ethyl phenyl-acetate. It was thought probable that a second form of diphenyl-acethydroxamic acid might be obtained, if the copper salt should be suspended in alcohol and decomposed by hydrogen sulfide, but such was not found to be the case.

**Benzoyl Ester:**  $(\text{C}_6\text{H}_5)_2\text{CH}.\text{CO}.\text{NHO}-\text{CO}.\text{C}_6\text{H}_5$ .—Three and five-tenths g. of diphenyl-acethydroxamic acid was dissolved in a warm solution of potassium hydroxide

<sup>32</sup> Schroeter, *Ber.*, **42**, 2345 (1909); Staudinger, *Ref.* 21, p. 144.

<sup>33</sup>  $\text{CO}_2$  reacts with  $\text{NH}_2\text{OH}$ .

just sufficient to cause the solution of the acid. Benzoyl chloride (1.65 cc.) was added in 4 portions. The reaction mixture was constantly agitated, while a stream of cold water was played over the flask. This gave 6 g. of crude dry product. Crystallization of this material from alcohol yielded plates which melted at 139.5–141°. Three recrystallizations caused the compound to have a sharp melting point, 140–140.5°. This ester is soluble in acetone, in ethyl acetate, in chloroform and in hot alcohol; slightly soluble in ether and in benzene, and insoluble in water, in ligroin and in a cold solution of sodium hydroxide. When the solution of sodium hydroxide is warmed, rearrangement takes place. When the ester was heated a little above its melting point, the odor of isocyanate became noticeable at once.

*Analysis.* Subs., 0.5417: N, 20.6 cc. (over 40% KOH, at 26° and 740.1 mm.) Calc. for  $C_{21}H_{17}O_3N$ : N, 4.22. Found: 4.13.

*Potassium Salt.*  $(C_6H_5)_2CH.CO.NK.O.CO.C_6H_5$ .—First Method. Alcoholic potassium hydroxide was prepared of such a strength that 1 cc.  $\approx$  0.113 g. of KOH. One cc. of this reagent was added to a solution of 0.67 g. of the benzoyl ester in a mixture of 15 cc. of absolute alcohol and 10 cc. of dry ether, previously cooled to –15°. There was no precipitation when a sample of the solution was diluted largely with ether, or with petroleum ether. Part of the solution was treated with silver nitrate to form the silver salt (see p. 2435). The rest was evaporated *in vacuo* over conc. sulfuric acid. For convenience, the residue left after evaporation of the solution will be called "R."

This residue (R) was shown to consist of a mixture of the desired potassium salt, together with diphenyl-methyl isocyanate, diphenyl-methyl urethane, and potassium benzoate. The part of (R) which was soluble in ether was extracted and half of this ether solution was evaporated. A residue remained which melted at 90° to 100°. Two recrystallizations of this material from benzene and ligroin resulted in the isolation of the urethane,  $(C_6H_5)_2CH.NH.CO.OC_6H_5$ , melting at 124°. The properties of this compound were confirmed by its preparation from diphenyl-acetamide, (see below).

The other half of the portion soluble in ether was shown to contain the isocyanate,  $(C_6H_5)_2CH.NCO$ , since an ether solution of benzhydriyl-amine added to it, caused an immediate precipitate of the urea, m. p. 268–270°, according to the equation,

Benzhydriyl-amine is without action upon an ether solution of the urethane.

The residue left from (R) after ether extraction was also divided into two parts. One part was analyzed and was found to contain a much greater percentage of potassium than that calculated for the potassium salt,  $(C_6H_5)_2CH.CO.NK.O.CO.C_6H_5$ .

*Analysis.* Subs., 0.1385:  $K_2SO_4$ , 0.0441. Calc. for  $C_{21}H_{16}O_3NK$ : K, 10.58. Found: 14.30.

This would indicate the presence of potassium benzoate as an impurity.

The other part dissolved in water to give a clear solution. A portion of the solution was boiled; this caused an immediate precipitation of *sym.* bi-diphenylmethyl urea, which confirms the presence of some potassium salt of the benzoyl ester. The remainder of the solution, acidified with dil. hydrochloric acid, gave a precipitate which, by fractional crystallization from alcohol, was resolved into the original benzoyl ester of diphenyl-acethydroxamic acid, m. p. 140°, and benzoic acid, m. p. 121°.

*Second Method.* A solution of potassium ethylate prepared from metallic potassium instead of potassium hydroxide gave no different results.

An interesting observation was made concerning the extreme solubility of the potassium salt. When 0.33 g. of the benzoyl ester was suspended in a cold mixture of 3 cc. of alcohol, and 6 cc. of ether, the undissolved ester went into solution when alcoholic potash was added.

**Third Method.** About 0.36 g. of silver salt,  $(C_6H_5)_2CH.CO.NAg.O.CO.C_6H_5$  (see preparation, below) suspended in 4 cc. of ice-water, was treated with 0.12 g. of potassium bromide, dissolved in a little water. The mixture was stirred frequently. After an hour, the precipitate had assumed the yellow color of silver bromide. Ample proof of metathesis was furnished when a little of the solution was filtered, and heated. A heavy crystalline precipitate of *sym.* bi-diphenylmethyl urea (m. p. 268–270°) separated. There appears to be no record of the use of silver salts in the preparation of alkali salts of hydroxamic acid.

The reaction mixture was kept at 0° overnight. Little, if any, decomposition occurred. One-third of the solution, after filtration, was acidified. The benzoyl ester precipitated in quantity. When a second portion of this solution was allowed to stand at room temperature, a gradual precipitation of the urea took place.

A portion of the solution containing the potassium salt was treated with silver nitrate, copper acetate, and cobalt nitrate solutions. The colors of the three precipitates were white, light green, and light pink respectively. These salts were not studied further.

**Sodium Salt.**  $(C_6H_5)_2CH.CO.N.Na.O.CO.C_6H_5$ .—A convenient solution of sodium ethylate to employ is one in which 1 cc.  $\approx$  0.023 g. of sodium. To a solution of 0.3 g. of benzoyl ester in 4 cc. of absolute alcohol and 15 cc. of ether, 0.9 cc. of the sodium ethylate solution was added. (The ester was in slight excess.) Just as with the potassium salt, here, also, no precipitate could be obtained. One portion of this solution was saved for the preparation of the silver salt, (see below) while a second portion of the solution was evaporated rapidly, and the residue extracted with water. Filtration from the insoluble matter left a clear solution that soon became turbid. A precipitate of the urea derivative was formed by boiling the solution.

The remainder of the ether-alcohol solution was evaporated *in vacuo* over conc. sulfuric acid. Ether caused the extraction of a large amount of the urethane, m. p., 123–124°. The portion insoluble in ether was shown by analysis to be chiefly sodium benzoate.

**Analysis.** Subs., 0.0558:  $Na_2SO_4$ , 0.0251. Calc. for  $C_{21}H_{15}O_2NNa$ : Na, 6.51. Calc. for  $C_6H_5.COONa$ : Na, 15.97. Found: 14.56.

**Silver Salt.**  $(C_6H_5)_2CH.CO.NAg.O.CO.C_6H_5$ .—First Method: from the potassium salt. The ether-alcohol solution of the potassium salt (see p. 2434) was treated with an aqueous solution of silver nitrate. The ether layer instantly assumed a deep yellow color, but remained clear. When this solution was shaken, a *pure white* precipitate of the silver salt formed, and the yellow color of the ether layer disappeared simultaneously.

**Analysis.** Subs., 0.1164: Ag, 0.0285. Calc. for  $C_{21}H_{15}O_2NAg$ : Ag, 24.62. Found: 24.49.

A little of the white salt, suspended in ether, did not cause the ether to assume a yellow color, even when alcohol was added. Here, again, as with the sodium or the potassium salt, there is evidence of the existence of two modifications, one of which is soluble in ether and alcohol, and the other insoluble. Gradual rearrangement occurred when the salt was heated gently; the odor of isocyanate was very marked. In a small tube the salt decomposed with a puff at about 145°.

**Second Method:** from the sodium salt. A similar procedure was followed with an ether-alcohol solution of the sodium salt (see above). In this case, the ether layer became yellow in color, and the precipitate which formed was yellow as well. The color of the salt gradually changed to pure white, and, in so doing, formed needle-shaped crystals. This change of color was hastened by scratching the precipitate with a glass rod. That the color change commenced at the surface was proved; for

yellow clumps that had apparently turned white, were found still to be yellow at the center. This material, when heated on a spatula, decomposed with a puff to form the isocyanate and a residue of metallic silver was left after ignition.

**Di-acetyl Ester,  $(C_6H_5)_2CH.CO.N(CO.CH_3).O.CO.CH_3$ .**—Apparently, the normal reaction of acetic anhydride and diphenyl-acethydroxamic acid leads to the formation of the di-acetyl ester, a trihydroxamic acid, instead of the mono-acetyl ester, even when half a mol. of acetic anhydride is used. In this case, a mixture of mono- and di-acetyl derivatives is obtained. By recrystallization from alcohol, the mixture was separated only with the greatest difficulty.

To prepare the di-acetyl ester, diphenyl-acethydroxamic acid (3 g.) was dissolved in a large excess of acetic anhydride (10 cc.). This solution was kept warm for 2 hours, and the excess of acetic anhydride was then evaporated in a vacuum desiccator containing powdered alkali. The solid ester, after recrystallization from alcohol, melted at 95.5–97.5°. It is soluble in hot alcohol, in ethyl acetate, in chloroform, in acetone and in benzene. It is but slightly soluble in ether, and is insoluble in water, in ligroin, or in a solution of sodium hydroxide.

**Analysis.** Subs., 0.5008: N, 19.8 cc. (over 40% KOH at 25° and 743.8 mm. (26°)). Calc. for  $C_{18}H_{17}O_4N$ : N, 4.50. Found: 4.34.

Two g. of the di-acetyl ester was distilled in a small flask heated by a metal bath. A liquid that weighed 0.45 g. was collected when the temperature of the bath rose to between 200° and 300°. This liquid all redistilled between 120° and 138°; this fraction consisted chiefly of acetic anhydride. When the residue in the flask was heated with a free flame, a liquid distilled at about 300° and left resinous materials in the flask. When the distillate was treated with an ether solution of benzhydriyl-amine to detect any diphenylmethyl isocyanate and then diluted with an equal quantity of petroleum ether, a tardy precipitate resulted; m. p. 136–137°. This was identified as benzhydriyl-amine acetate; no *sym.* bi-diphenylmethyl urea could be found.

**Benzhydriyl-amine Acetate,  $(C_6H_5)_2CH.NH_2O.COCH_3$ .**—A sample of benzhydriyl-amine acetate was prepared by mixing an ether solution of benzhydriyl-amine with glacial acetic acid. White crystalline plates separated, which melted at 138°. The salt dissolved readily in water.

**Mono-acetyl Ester,  $(C_6H_5)_2CH.CO.NH—O—CO.CH_3$ .**—In order to avoid the formation of the di-acetyl ester, precautions had to be taken to destroy the acetic anhydride as soon as the reaction mixture showed no mono-hydroxamic acid. Ferric chloride was used as an indicator. Three g. of diphenyl-acethydroxamic acid was dissolved rapidly in an excess of warm acetic anhydride (10 cc.), and, after about 30 seconds, the reaction was stopped by the addition of 50 cc. of cold water. A white precipitate, chiefly the mono-acetyl ester, resulted. Two recrystallizations gave crystalline plates of pure substance melting at 113–113.5°.

The acetyl ester dissolves in acetone, in chloroform, in ethyl acetate, in benzene and in alcohol. It is insoluble in a cold solution of sodium hydroxide and in ligroin, and only slightly soluble in ether. When the solution of sodium hydroxide is warmed, rearrangement takes place.

**Analysis.** Subs., 0.3046: N, 14.1 cc. (over 40% KOH at 23.5° and 738.8 mm. (19°)). Calc. for  $C_{18}H_{15}O_3N$ : N, 5.20. Found: 5.09.

**Potassium Salt.**— $(C_6H_5)_2CH.CO.NK.O.CO.CH_3$ .—One-third of a gram of acetyl ester dissolved quite readily in 5 cc. of cold alcohol. The solution was diluted with 10 cc. of ether and was then chilled to –10° by means of a freezing mixture of ice and conc. sulfuric acid. To this solution, 0.6 cc. of alcoholic potash solution (see p. 2434) was added. Here again, no precipitate formed, even when an excess of ether was

added. Part of the liquid was evaporated; the residue was extracted with ether, dried and analyzed.

*Analysis.* Subs., 0.0929:  $K_2SO_4$ , 0.0293. Calc. for  $C_{16}H_{14}O_2NK$ : K, 12.72. Found: 14.15.

This high result is explained by the presence of potassium acetate, a decomposition product.

The remainder of the solution, which still contained the potassium salt, was diluted with 10 cc. of petroleum ether. There was no precipitate. If it was shaken with a dil. solution of silver nitrate in water, a white silver salt was obtained (see below).

*Sodium Salt.*—About 0.3 g. of the acetyl ester was dissolved in 2 to 3 cc. of absolute alcohol, and diluted to 15 cc. with ether. This solution, cooled with ice, was treated with 0.8 cc. of sodium ethylate solution (see p. 2435). There was a tardy precipitation that gradually became quite heavy. The addition of ether hastened its formation. This material, collected and washed with ether, was dried and analyzed. Its sodium content was found to be midway between that required for  $(C_6H_5)_2CH.CO.NNa.O.COCH_3$  and that for sodium acetate.

*Analysis.* Subs., 0.0634:  $Na_2SO_4$ , 0.0346. Calc. for  $C_{16}H_{14}O_2NNa$ : Na, 7.90. Calc. for  $CH_3.COONa$ : Na, 28.05. Found: 17.67.

*Silver Salt.*—The ether-alcohol solution of the potassium salt, when mixed with aqueous silver nitrate, formed a pure white precipitate. It was found best not to wash the salt with alcohol, since that frequently caused it to turn dark. The white precipitate was washed carefully with water, dried, and analyzed. When it was heated in a small tube, it decomposed between  $103^\circ$  and  $110^\circ$ . The isocyanate, recognized by its characteristic odor, distilled.

*Analysis.* Subs., 0.0738: Ag, 0.0213. Calc. for  $C_{16}H_{14}O_2NAg$ : Ag, 28.69. Found: 28.86.

In order to establish the identity of the products of rearrangement isolated in these reactions, they were prepared in a different manner. Some of them represent new compounds, not previously described.

*Diphenylmethyl Urethane*,  $(C_6H_5)_2CH.NH.COOC_2H_5$ .—A method, similar to that developed by Stieglitz and his students,<sup>34</sup> was employed successfully in the preparation of this urethane. A solution of sodium ethylate was made by the action of 3.42 g. of sodium upon 160 cc. of alcohol. Nine g. of diphenyl-acetamide was suspended in it, and caused to dissolve by the rapid addition of 4.1 cc. of bromine. Without filtration to remove sodium bromide, the neutral mixture was boiled for 10 minutes, after which the alcohol was distilled. The urethane was precipitated by the addition of an excess of water. Yield, 8 g. Nothing except sodium bromide was found in the filtrate. The precipitate was extracted with 50 cc. of hot benzene. One g. of material, later proved to be *sym.* bi-diphenylmethyl urea, was insoluble. When the benzene became cool, 1.8 g. of unchanged amide (m. p.  $161^\circ$ ) precipitated. The benzene filtrate contained nearly pure diphenylmethyl urethane. After evaporation of the solvent, the residue was pressed on a clay plate. Yield, 4.2 g. It may be recrystallized from a mixture of benzene and ligroin, or of alcohol and water; m. p.  $122-123^\circ$ . It is soluble in alcohol, in chloroform, in acetone, in ethyl acetate, and in benzene, but insoluble in water and in ligroin.

*Analysis.* Subs., 0.4130: N, 20.69 cc. (over 40% KOH at  $20^\circ$  and 763.9 mm. ( $16^\circ$ )). Calc. for  $C_{16}H_{14}O_2N$ : N, 5.49. Found: 5.64.

*Diphenylmethyl urea chloride*,  $(C_6H_5)_2CH.NH.CO.Cl$ .—Two g. of the urethane

<sup>34</sup> Jeffreys, *Ber.*, 30, 898 (1897); *Am. Chem. J.*, 22, 27 (1899); Polin, *Am. Chem. J.*, 19, 324 (1897).

and 1.63 g. of phosphorus pentachloride were dissolved in 10 to 15 cc. of dry chloroform. This mixture was warmed, and a current of dry hydrogen chloride was bubbled through the solution. This served to expel phosphorus oxychloride and also to prevent the decomposition of the urea chloride which would yield the more volatile isocyanate. Chloroform was added twice as the solution evaporated. Finally, when the solvent was nearly exhausted, petroleum ether was added, and the entire solution was poured through a filter. A solid mixed with oil resulted when the filtrate was evaporated.

**Diphenylmethyl Isocyanate,  $(C_6H_5)_2CH.NCO$ .**—The crude urea chloride was extracted with benzene, and the solution filtered. Some calcium oxide was placed in the flask, and the mixture was left in the stoppered flask for 3 hours. This solution contained the isocyanate (see below). After filtration, it was not purified further, but was treated at once with benzhydryl-amine to form the urea.

**Benzhydryl-amine,  $(C_6H_5)_2CH.NH_2$ .**—This compound was prepared by reducing benzophenone oxime with metallic sodium and alcohol. It has been prepared from benzophenone oxime by Goldschmidt,<sup>35</sup> who employed sodium amalgam, and also by Michaelis<sup>36</sup> from benzophenone-phenylhydrazone with metallic sodium and alcohol.

Five g. of dry benzophenone oxime was suspended in 50 cc. of absolute alcohol. The mixture was poured through a reflux condenser upon a piece of sodium which weighed 12 g. The oxime dissolved at once, and enough heat was generated to melt the sodium. A little alcohol was introduced from time to time. After 40 minutes, when all the sodium had dissolved, most of the alcohol was recovered by distillation, and water was added to the residue. After partial neutralization of the alkaline solution, benzhydryl-amine was extracted by means of ether, and the ether solution was dried over potassium hydroxide. To precipitate benzhydryl-amine hydrochloride, it was only necessary to add conc. hydrochloric acid to the ether solution. Between 5.5 and 6 g. of the salt was collected.

**Sym. bi-diphenylmethyl Urea,  $CO(NH.CH(C_6H_5)_2)_2$ .**—The benzene solution of the isocyanate (see above) was treated with an ether solution of benzhydryl-amine. There was a tardy precipitation of solid which was collected after a few hours and shown to consist of a mixture of benzhydryl-amine hydrochloride, and the urea. The former, produced because of some unchanged urea chloride, was soluble in very dilute hydrochloric acid; it melted at 276–280°. The portion insoluble in the acid melted at 266°. It was rather soluble in hot acetone and in hot ethyl acetate. Recrystallization from either of these solvents produced fine needle-shaped crystals of the urea which melted at 269.5–270°.

**Analysis.** Subs., 0.3246: N, 19.90 cc. (20° and 763.9 mm. (16°)). Calc. for  $C_{24}H_{24}ON_2$ : N, 7.14. Found: 7.07.

## 2. Triphenyl-acethydroxamic Acid.

**Triphenyl-acetyl chloride,  $(C_6H_5)_3C.COCl$ .**—Schmidlin and Hodgson<sup>37</sup> prepared triphenyl-acetyl chloride from triphenyl-acetic acid, acetyl chloride and phosphorus pentachloride. In the same year Bistrzycki and Landtwig<sup>38</sup> described a method of preparation in which phosphorus oxychloride was used as a solvent, instead of acetyl chloride.

It may be prepared much more simply with thionyl chloride as the chlorinating agent. Three g. of triphenylacetic acid and 10 cc. of thionyl chloride were placed

<sup>35</sup> Goldschmidt, *Ber.*, 19, 3233 (1886).

<sup>36</sup> Michaelis, *ibid.*, 26, 2168 (1893).

<sup>37</sup> Schmidlin and Hodgson, *ibid.*, 41, 438 (1908).

<sup>38</sup> Bistrzycki and Landtwig, *ibid.*, 41, 687 (1908).

in a small flask equipped with an air condenser, and gently warmed until solution was complete. The liquid was boiled for about 5 minutes after gas evolution (sulfur dioxide and hydrogen chloride) had ceased. Then, it was cooled and poured upon crushed ice to decompose any excess of thionyl chloride. (If larger quantities were employed, it would be better of course, to recover the thionyl chloride by distillation.) The solid triphenylacetyl chloride was filtered, washed with a little cold water, pressed upon a porous plate, and then dried in a vacuum desiccator. Without further treatment, the material obtained was pure enough for most purposes. It melted at  $127^{\circ}$ . The yield was practically quantitative.

Thionyl chloride readily dissolved both triphenylacetyl chloride, and ethyl triphenylacetate, and it was without action upon either one.

**Triphenylacethydroxamic Acid.**—Two and five-tenths g. of triphenylacetyl chloride was dissolved in 40 cc. of dry benzene. This was poured into a flask containing 2.5 g. of free hydroxylamine. The mixture was agitated at frequent intervals during an hour, and then was put aside until the next day. Since there was no precipitation of hydroxamic acid, the benzene layer was decanted from the excess of hydroxylamine, placed in a distilling flask, and the solvent was distilled. An oil remained which crystallized readily when it became cool. Petroleum ether caused an additional precipitate. More than 2 g. of crystals was obtained. The crude substance melted at  $172^{\circ}$ .

Triphenylacethydroxamic acid is soluble in a warm solution of sodium hydroxide, in benzene, in acetone, in ethyl acetate and in alcohol. It is insoluble in ligroin, and in water. Recrystallization from ether produced a pure product which melted at  $175\text{--}176^{\circ}$ .

An alcoholic solution, treated with ferric chloride, gave the usual red color reaction. Furthermore, copper acetate formed a light green copper salt.

*Analysis.* Subs., 0.3858: N, 16.14 cc. (over 40% KOH at  $21.8^{\circ}$  and 758.9 mm. ( $18^{\circ}$ )). Calc. for  $C_{26}H_{17}O_2N$ : N, 4.62. Found: 4.75.

Attempts to prepare triphenylacethydroxamic acid by the action of free hydroxylamine upon ethyl triphenylacetate,  $(C_6H_5)_3C.CO.OC_2H_5$ , resulted in failure. There was no action, even when an excess of sodium ethylate was present. In all cases the ester was recovered unchanged.

When triphenylacetyl chloride was employed with a mixture of hydroxylamine and sodium carbonate in water, it was very difficult to purify the triphenylacethydroxamic acid.

**Benzoyl Ester,**  $(C_6H_5)_3C.CO.NH.O.CO.C_6H_5$ .—First Method. One-tenth g. of triphenylacethydroxamic acid was fused with a considerable excess of benzoic anhydride until a sample gave no reaction with ferric chloride. The excess of anhydride was then extracted several times with warm ligroin ( $50^{\circ}$ ). An oil was left which refused to solidify in the course of a week. It was extracted with a very dilute, cold solution of sodium hydroxide. This solution was filtered and acidified immediately. A white solid precipitated, m. p.  $40\text{--}50^{\circ}$ . When this process was repeated the benzoyl ester was obtained in a somewhat purer state. It melted between  $44^{\circ}$  and  $47^{\circ}$  for the most part, but there was a little that did not melt until the temperature reached  $70^{\circ}$ . It is highly probable that, even at this low temperature, the ester decomposed to a slight extent into benzoic acid and triphenylmethyl isocyanate, which may account for the anomalous melting point (see p. 2429).

This low-melting ester was found to be extremely soluble in organic solvents. From benzene solution, petroleum ether precipitated it as an oil which could not be made to crystallize, even after the removal of the solvent.

By careful hydrolysis with alkalis, it was possible to convert part of the ester into triphenylacethydroxamic acid. The greater tendency by far, however, was

rearrangement of the salt in solution, not to form the urea derivative, as would be anticipated, *but to give the isocyanate*,  $(C_6H_5)_3C.NCO$ .

**Second Method.** Because of the instability of the sodium salt of the benzoyl ester of triphenylacethydroxamic acid, this method (Schotten-Baumann reaction) is less successful than the first method. One and six-tenths g. of triphenylacethydroxamic acid was dissolved in 15 cc. of water that contained 0.23 g. of sodium hydroxide. The solution was cooled in a stream of tap water, and 0.6 cc. of benzoyl chloride was added in 3 portions.

No attempt was made to purify the sticky solid. Instead, it was washed thoroughly with water, then dried, and converted into its salts.

**Potassium Salt.**  $(C_6H_5)_3C.CO.NK.O.CO.C_6H_5$ .—The crude benzoyl ester was dissolved in 1.5 cc. of absolute alcohol. This solution was treated with a solution of potassium hydroxide (0.11 g.) in alcohol. Since 20 cc. of ether caused no precipitation of salt, a solution of silver nitrate in water was added. This gave the silver salt.

**Silver Salt.**  $(C_6H_5)_3C.CO.NAg.O.CO.C_6H_5$ .—A white precipitate formed, which turned canary-yellow in a short time. It was filtered and washed thoroughly with water, and with ether. In a small tube, this salt became gray in color at  $120^\circ$ ; it was black at  $160^\circ$ ; and at  $195^\circ$  it melted with much decomposition.

**Analysis.** Subs., 0.1444: Ag, 0.0300. Calc. for  $C_{27}H_{20}O_2NAg$ : Ag, 20.98. Found: 20.85.

**Acetyl Ester,**  $(C_6H_5)_3C.CO.NH.O.CO.CH_3$ .—A large excess of warm acetic anhydride (about 3 cc.) was used to dissolve 0.6 g. of triphenylacethydroxamic acid. In about half a minute a test with ferric chloride showed that the reaction was complete. In order to stop any further action which might lead to the formation of a di-acetyl ester, 10 cc. of cold water was added to decompose any unused anhydride. In a short time, the acetyl ester solidified to form a white solid. It was filtered and dried. Very few impurities were present in this crude material. One recrystallization from a mixture of 2 cc. of benzene and 10 cc. of ligroin gave a pure product that melted at  $133.5$ – $134^\circ$ . The ester was very soluble in most common organic solvents. The yield was quantitative.

**Analysis.** Subs., 0.2156: N, 7.62 cc. ( $20^\circ$  and 762.2 mm.). Calc. for  $C_{22}H_{19}O_2N$ : N, 4.06. Found: 4.08.

**Potassium Salt.**  $(C_6H_5)_3C.CO.NK.O.CO.CH_3$ .—When 0.38 g. of the acetyl ester was dissolved in a small quantity of absolute alcohol and neutralized with 0.55 cc. of alcoholic caustic potash (0.062 g. of potassium hydroxide), a little ether caused the separation of a gelatinous precipitate, which was collected upon a filter. The material would not dissolve to give a clear solution in cold water. It was evident that the unstable potassium salt suffered rearrangement in solution, because the solution, turbid at first, rapidly became white and opaque. When the solution was boiled, the potassium salt was decomposed completely; triphenylmethyl isocyanate was precipitated. The dry salt decomposed slightly at  $112^\circ$ . At  $165^\circ$  there was a vigorous evolution of gas.

**Analyses.** Subs., 0.0400, 0.1253:  $K_2SO_4$ , 0.0080, 0.0252. Calc. for  $C_{22}H_{18}O_2NK$ : K, 10.19. Found: 8.98, 9.03.

**Sodium Salt.**—Sodium ethylate and ether did not cause a precipitate when added to a solution of the acetyl ester in alcohol. Accordingly, the solution was treated with an aqueous solution of silver nitrate to form the silver salt.

**Silver Salt.**—This was thrown down at once as a yellow precipitate, but the quantity was insufficient to warrant an analysis. When heated upon a spatula it decomposed at a fairly high temperature and left a residue of metallic silver.

**Triphenylmethyl Isocyanate,**  $(C_6H_5)_3C.NCO$ .—When a solution of the potassium

salt of the acetyl ester of triphenylacethydroxamic acid was boiled for a short time with water, an oil was formed. In the course of a few hours this oil solidified. It was collected, and washed with water. The isocyanate was very soluble in organic solvents, even in ligroin. It was dissolved in petroleum ether, filtered into an open dish, and most of the solvent evaporated in a vacuum desiccator. White crystals were formed in this manner, m. p. 85–87°.

*Analysis.* Subs., 0.1518: N, 6.72 cc. (17° and 757 mm. (18°)). Calc. for  $C_{23}H_{18}ON$ : N, 4.91. Found: 5.12.

The solubility in petroleum ether, and the low melting point are sufficient evidence that this compound could not be *sym.* bi-triphenylmethyl urea,  $CO(NH.C(C_6H_5)_3)_2$ . Although E. von Meyer and P. Fischer<sup>29</sup> claim to have prepared this urea, none of its properties, not even the melting point, was described. It can be predicted, however, that the melting point is very high.

In order to prove that the material in hand was the isocyanate, it was dissolved in ether, and treated with the calculated quantity of aniline, also dissolved in ether. Upon evaporation of the ether, a white solid was left which melted sharply at 242°. This was anticipated, since phenyl-triphenylmethyl urea,  $C_6H_5.NH-CO.NH.C(C_6H_5)_3$ , which has been prepared<sup>29</sup> previously, was known to melt at that temperature.

### 3. Pyromucyl-hydroxamic Acid.

The procedure described by Pickard and Neville<sup>24</sup> for the preparation of pyromucyl-hydroxamic acid employed ethyl pyromucate and hydroxylamine in alcoholic solution. It was purified through the medium of the insoluble copper salt. Our modification of the method consists in the addition of a mol of sodium ethylate, and the direct recovery of the hydroxamic acid without the intermediate formation of the copper salt.

Thirty g. of methyl pyromucate was poured into 150 cc. of a methanol solution of free hydroxylamine which had been liberated from 19.5 g. of its hydrochloride by a solution of sodium methylate containing 6.4 g. sodium. A solution of 5.4 g. of sodium in 70 cc. of methanol was then added to the mixture and, after 10 hours, as light excess of conc. hydrochloric acid was introduced. Sodium chloride was separated and the methanol removed by distillation *in vacuo*. An oil was left which solidified after a few hours in a vacuum desiccator. One crystallization from water brought the melting point to 119–122°. Twenty-four g. of this material was obtained. Three g. of the copper salt was precipitated from the solvent used in recrystallization.

The acid is soluble in alcohol, in ethyl acetate, and in water. In benzene, in chloroform, in carbon disulfide, in ligroin, and in ether it is insoluble.

*Ammonium Salt.*  $(C_4H_5O.CO.NH.O)_2H.NH_4$ .—Ammonium hydroxide caused the precipitation of beautiful crystalline plates, when added to an aqueous solution of pyromucyl-hydroxamic acid. (Cf. p. 2444.) This precipitate was soluble either in an excess of ammonium hydroxide, or in dilute acid, which indicated that the salt is the acid salt and not the normal salt. In the former case, the normal salt is undoubtedly obtained, whereas with acids, the soluble pyromucyl-hydroxamic acid is restored. The salt melted at 130–131°, with considerable gas evolution. The analysis gave the same values whether the salt was prepared in this manner, or in the absence of water, by the action of dry ammonia upon an alcohol-ether solution of pyromucyl-hydroxamic acid.

<sup>29</sup> von Meyer and Fischer, *J. prakt. Chem.*, [2] 82, 521 (1910).

*Analyses.* (I) Prepared in the presence of water. Subs., 0.1114: N, 15.9 cc. (over 40% KOH at 27° and 737.9 mm.); (II) prepared in the absence of water; subs., 0.2126: N, 27.58 cc. (17.3° and 772.6 mm. (15°)). Calc. for  $C_{10}H_{12}O_5N_2$ ; N, 15.49. Found: (I) 15.41, (II) 15.30.

**Benzoyl Ester,  $C_6H_5O.CO.NH.OCO.C_6H_5$ .**—Pickard and Neville<sup>40</sup> stated that this derivative "is precipitated when an aqueous solution of the hydroxamic acid is shaken with the calculated quantity of benzoyl chloride, and sodium acetate." Potassium hydroxide was found to be far superior to sodium acetate. Three g. of pyromucyl-hydroxamic acid, and 1.3 g. of potassium hydroxide were dissolved in 20 cc. of water, and 2.7 cc. of benzoyl chloride was added in 4 portions. A quantitative yield of the benzoyl ester resulted. After recrystallization from alcohol, the compound melted at 140°. <sup>41</sup>

**Preparation of Salts.**—The following general method was employed in the preparation of the potassium and the sodium salts of the esters. Alcoholic solutions of sodium ethylate, or of potassium ethylate were added to concentrated alcoholic solutions of the esters. The salt usually precipitated at once. It was found advantageous to add the alcoholate in a slight excess. Three or four volumes of ether were added to effect a complete separation of the salt.

To prepare the silver salts, it was necessary only to add a solution of silver nitrate in water, to an aqueous solution of the potassium salt. In most cases this could be done at room temperature, but in a few cases a lower temperature was required to inhibit any hydrolysis.

**Potassium Salt,  $C_6H_5O.CO.NK.O.CO.C_6H_5$ .**—The appearance of the dry salt was unchanged after 8 months. In a small tube, it puffed at 125°.

*Analysis.* Subs., 0.4337:  $K_2SO_4$ , 0.1380. Calc. for  $C_{12}H_9O_4NK$ : K, 14.52. Found: 14.28.

**Sodium Salt.**<sup>42</sup>—This salt was white when first formed, but in 3 months the color was distinctly yellow.

**Silver salt.**—The silver salt was pure white.

*Analysis.* Subs., 0.1289: Ag, 0.0413. Calc. for  $C_{12}H_9O_4NAg$ : Ag, 31.92. Found: 32.04.

All of these salts showed a decided tendency to undergo hydrolysis. The potassium salt, dissolved in cold water, gave a ferric chloride color test in a very short time. Similarly, a little of the silver salt suspended in boiling water, caused a separation of black silver, a reaction characteristic of monohydroxamic acids.

When a 0.5 *M* solution of the potassium salt was warmed carefully to about 70°, crystals were precipitated which were unmistakably identified as the benzoyl ester. By careful application of heat, the filtrate gave a still more abundant yield of the same ester. If the filtrate from this precipitate was heated to boiling, a red resinous mass accompanied by the evolution of much carbon dioxide, was formed. This was dried, and then recrystallized twice from a mixture of alcohol and ether. After this treatment, it was still colored. The material darkened at 180°, and melted at 210° with decomposition. This is presumably *sym. difuryl urea*, although enough was not obtained for analysis.

If the solution of the potassium salt was heated immediately to boiling, the same resinous mass was produced, but the separation of the benzoyl ester did not occur.

**Acetyl Ester,  $C_4H_5O.CO.NH.O.COCH_3$ .**—Three g. of pyromucyl-hydroxamic acid

<sup>40</sup> Ref. 24, p. 848.

<sup>41</sup> That obtained by Pickard and Neville melted at 134°.

<sup>42</sup> This salt was previously prepared by Pickard and Neville.

and an excess (3 cc.) of acetic anhydride were warmed until solution occurred. The excess of anhydride was evaporated in a vacuum desiccator. The white crystalline mass was pressed upon a porous plate, and recrystallized from water. It melted at 95–96°. This ester is soluble in alcohol, in ethyl acetate, in chloroform, in acetone, in hot benzene and in hot water. It is insoluble in ether and in ligroin.

*Analyses.* Subs., 0.3526, 0.2920: N, 26.1 cc. (over 40% KOH at 24.5° and 740.3 mm. (26.5°)), 21.6 cc. (26° and 743.8 mm.). Calc. for  $C_7H_7O_4N:N$ , 8.28. Found: 8.09, 8.08.

*Potassium salt.*—The appearance of this salt was unchanged after standing for 8 months.

*Analysis.* Subs., 0.3325:  $K_2SO_4$ , 0.1403. Calc. for  $C_7H_6O_4NK$ : K, 18.87. Found: 18.98.

*Sodium salt.*—Alcoholysis of the salt could not be prevented, even when it was prepared at 0°. The salt of pyromucyl-hydroxamic acid was shown to be present when it was treated with a solution of ferric chloride, by the appearance of a deep purple color. It was expected, therefore, that the percentage of sodium in the sample would be higher than that required by the sodium salt of the acetyl ester of pyromucyl-hydroxamic acid.

*Analyses.* Subs., 0.2667, 0.1064:  $Na_2SO_4$ , 0.1133, 0.0436. Calc. for  $C_7H_6O_4NNa$ : Na, 12.14. Found: 13.75, 13.27.

A still higher sodium content was found when methanol, at 0°, replaced ethyl alcohol in its preparation. After 3 months the salt was bright yellow in color.

*Analysis.* Subs., 0.1032:  $Na_2SO_4$ , 0.0470. Found: Na, 14.75.

*Silver salt.*—It was necessary to prepare this derivative at 0°. When the salt was prepared at room temperature, hydrolysis to give the monohydroxamic acid was indicated by the formation of a black precipitate of metallic silver.

*Analysis.* Subs., 0.0982: Ag, 0.0382. Calc. for  $C_7H_6O_4NAg$ : Ag, 39.09. Found: 38.90.

Both the rearrangement and the hydrolysis of these salts were perfectly analogous to the behavior shown by the salts of the benzoyl ester; except that in this case the tendency to hydrolyze appeared greater.

#### 4. Thenhydroxamic Acid.

*First Method.*—A solution of free hydroxylamine in methanol was prepared by mixing Solutions A, and B, composed, respectively of, 4.90 g. of hydroxylammonium chloride in 50 cc. of methanol, and 35 cc. of methanol to which 1.67 g. of sodium had been added. Sodium chloride was removed by filtration.

Nine and six-tenths g. of thenoic ethyl ester,  $C_4H_5S-CO.OC_2H_5$ , previously purified by distillation *in vacuo*, was added to the alcoholic solution of hydroxylamine, followed by one mol of sodium methylate (1.42 g. of sodium in 30 cc. of methanol), and the mixture was allowed to stand overnight. Then 5 cc. of conc. hydrochloric acid was used to precipitate the sodium as sodium chloride. The solvent distilled *in vacuo*, after filtration to remove the salt, left a thick liquid which was placed in a vacuum desiccator to crystallize. The solid obtained in this way, crystallized from water, melted at 105–113°. Recrystallization from toluene resulted in pure material, m. p. 123–124.5°.

A water solution of thenhydroxamic acid is acid to litmus. With ferric chloride

and copper acetate, it reacts in the normal manner, to give respectively, a purple colored liquid, and a grass-green copper salt. The acid is soluble in alcohol, in hot toluene, in hot benzene, in chloroform, and in water. It is insoluble in ether and in ligroin. With isatin, and warm sulfuric acid the red color characteristic of thiophene derivatives is produced.

*Analysis.* Subs., 0.2259: N, 19.12 cc. (over 40% KOH at 18.5° and 757.8 mm.). Calc. for  $C_8H_5O_2NS$ : N, 9.78. Found: 9.74.

Isolation of thenhydroxamic acid through the medium of the copper salt and hydrogen sulfide was found to be successful, but the procedure is not to be recommended.

The Preparation of  $\alpha$ -Thenoyl Chloride,  $C_8H_5S.COCl$ .—Thenoyl chloride has always been prepared from thenoic acid by the action of phosphorus pentachloride.<sup>43</sup> A much simpler, and smoother preparation follows if thionyl chloride,  $SOCl_2$ , is employed instead of the phosphorus compound.

Six g. of  $\alpha$ -thenoic acid was warmed with 16 cc. of thionyl chloride until the gas evolution showed that the reaction was complete, when the two chlorides were separated by fractional distillation. Thenoyl chloride all distilled between 206° and 210°; yield, 6 g.

$\alpha$ -Thenhydroxamic Acid. Second method.—A solution of 0.3 g. of sodium carbonate, and 0.2 g. of hydroxylammonium chloride in 2.5 cc. of water was shaken with 0.3 g. of thenoyl chloride. Di-thenhydroxamic acid  $C_8H_5S.CO.NH.O.CO.C_8H_5S$  (see p. 2445) precipitated from the solution, whereas thenhydroxamic acid did not. To recover the latter, the filtrate was made slightly acid with acetic acid, and treated with copper acetate solution. The light green copper salt precipitated, although the green color of the solution showed that it possessed a rather high degree of solubility. The filtrate still gave an intense ferric chloride reaction.

The precipitate of di-thenhydroxamic acid was recrystallized from alcohol and water. It melted at 105–107°. We did not try to prepare thenhydroxamic acid by our new method, *viz.*, by the action of free hydroxylamine and a benzene solution of thenoyl chloride. No side reactions would be anticipated in this case.

*Ammonium Salt.*  $(C_8H_5S.CO.NH.O)_2H.NH_4$ .—This difficultly soluble acid salt was prepared in exactly the same way as the similar furan salt, (p. 2441) and showed the similar property of dissolving either in ammonia, or in hydrochloric acid. For analysis, the salt was precipitated from an alcohol-ether solution of thenhydroxamic acid by dry ammonia. It melted, with decomposition, at 142–143°.

*Analysis.* Subs., 0.1172: N, 13.95 cc. (21° and 769 mm. (20°)). Calc. for  $C_{10}H_{10}O_4N_2S_2$ : N, 13.85. Found: 13.75.

*Benzoyl Ester*,  $C_8H_5S.CO.NH.O.CO.C_6H_5$ .—Two g. of thenhydroxamic acid, and 0.8 g. of potassium hydroxide were dissolved in 10 cc. of water. This solution, agitated with 1.7 cc. of benzoyl chloride, gave a precipitate which was recrystallized from alcohol. The needle shaped crystals so obtained melted sharply at 143–144°, with decomposition. It is soluble in alcohol, in acetone and in ethyl acetate, and is insoluble in ligroin, or in cold water.

*Analysis.* Subs., 0.4336 g.: N, 21.97 cc. (at 21° and 758.6 mm. (at 19°)). Calc. for  $C_{12}H_9O_4NS$ : N, 5.67. Found: 5.77.

*Potassium Salt.*—The general method described upon p. 2422, was used also to prepare the salts in this series. The potassium salt was pure white. When it was heated in a small dry tube, it became yellow at 121° and decomposed with a faint puff at 125–127°.

*Analysis.* Subs., 0.5313:  $K_2SO_4$ , 0.1626. Calc. for  $C_{12}H_9O_4NSK$ : K, 13.71. Found: 13.73.

<sup>43</sup> V. Meyer and Kreis, *Ber.*, 16, 2174 (1883); Peter, *Ber.*, 18, 543 (1885).

*Sodium Salt.*—When slowly heated, the sodium salt decomposed mildly between 155° and 160°.

*Analysis.* Subs., 0.2388:  $\text{Na}_2\text{SO}_4$ , 0.0631. Calc. for  $\text{C}_{12}\text{H}_5\text{O}_2\text{NSNa}$ : Na, 8.54. Found: 8.55.

*Silver Salt.*—The silver salt decomposed between 163° and 168°. Above this temperature thienyl isocyanate distilled from the tube.

*Analysis.* Subs., 0.2364: Ag, 0.0723. Calc. for  $\text{C}_{12}\text{H}_5\text{O}_2\text{NSAg}$ : Ag, 30.47. Found: 30.58.

*Rearrangement of the Salts.*—A 0.5*M* solution of the potassium salt in water was boiled. The solution darkened, and di-thienyl urea precipitated as a gray-violet crystalline mass.<sup>44</sup> It was collected and recrystallized from acetic acid. The melting point was 224–225°.

The filtrate was acidified and the precipitate obtained was crystallized fractionally from dilute alcohol. Crystals melting at 140–144° separated at first. This material was the benzoyl ester, which must have been formed by hydrolysis of the salt. Benzoic acid was left in the filtrate. The ratio of the urea to the benzoyl ester was about 4:1.

*Acetyl Ester*,  $\text{C}_6\text{H}_5\text{S.CO.NH.O.CO.CH}_3$ .—Three-tenths g. of pure thenhydroxamic acid was warmed in an open glass dish with 0.2 g. of acetic anhydride. As soon as solution had taken place, the dish was placed in a vacuum desiccator to remove the excess of anhydride. The white solid obtained was recrystallized from benzene. The melting point was sharp at 96.5–97°; yield, quantitative. The ester is soluble in alcohol, in ethyl acetate, and in hot benzene, but is insoluble in cold benzene and in ligroin.

*Analysis.* Subs., 0.3242: N, 21.47 cc. (over 40% KOH at 17.8° and 760.3 mm. (15°)). Calc. for  $\text{C}_7\text{H}_7\text{O}_2\text{NS}$ : N, 7.57. Found: 7.66.

*Potassium Salt.*—No precautions were necessary to prepare the potassium salt

*Analysis.* Subs., 0.3099:  $\text{K}_2\text{SO}_4$ , 0.1215. Calc. for  $\text{C}_6\text{H}_5\text{O}_2\text{NSK}$ : K, 17.51. Found 17.49.

*Sodium Salt.*—Ice-cold solutions were essential in the preparation of the sodium salt. Otherwise, alcoholysis to yield the monohydroxamic acid occurred.

*Analysis.* Subs., 0.0609:  $\text{Na}_2\text{SO}_4$ , 0.0209. Calc. for  $\text{C}_7\text{H}_5\text{O}_2\text{NSNa}$ : Na, 11.10. Found: 11.11.

*Silver Salt.*—Because of hydrolysis, a water solution of the sodium salt could not be used to prepare the silver salt. A black precipitate of silver always resulted. With the potassium salt, however, the preparation was entirely successful.

*Analysis.* Subs., 0.1481: Ag, 0.0548. Calc. for  $\text{C}_7\text{H}_5\text{O}_2\text{NSAg}$ : Ag, 36.94. Found: 37.00.

These salts all puffed at a comparatively high temperature. A pronounced odor of thienyl isocyanate was always noticed. When water solutions of the salts were boiled, di-thienyl urea separated instantly. However, this was always accompanied by an unavoidable hydrolysis to form the acetyl ester and a second hydrolysis to give thenhydroxamic acid.

*Thenoyl Ester*, (Di-thenhydroxamic Acid),  $\text{C}_6\text{H}_5\text{S.CO.NH.O.CO.C}_6\text{H}_5\text{S}$ .—One preparation of this ester (Cf. p. 2444) which resulted in the high-melting modification (see below) has already been described.

Three g. of thenhydroxamic acid, and 1.18 g. of potassium hydroxide were dissolved in 15 cc. of water. The ice-cold mixture was treated with 3 portions (1 g. each)

<sup>44</sup> *Sym.* di-thienyl urea was found by Curtius and Thyssen<sup>39</sup> to be gray-violet in color, even after 7 recrystallizations from solvents with animal charcoal; m. p. 224°.

of thenoyl chloride. A precipitate which weighed 2.7 g. was collected; m. p. between 80° and 88°.

The filtrate was found to be acid in reaction, and to contain some unchanged thenhydroxamic acid. It was therefore made slightly alkaline with sodium hydroxide and treated with 2 cc. of thenoyl chloride. The resulting precipitate melted at 90–100° and weighed 1.4 g. When the filtrate was acidified, an appreciable quantity of thenoic acid separated.

The crude precipitates, (m. p. 80–100°) were combined and recrystallized from benzene. Crystals which melted between 83° and 86° were obtained. Later a re-determination of the melting point of this same sample indicated that a transformation to a higher-melting modification had taken place. The melting point ranged from 100° to 104°.

When alcohol was used as the solvent, the high melting modification separated first. There was an indication of softening at 95°, but the melting point at 102–104° was quite distinct.

Both of these compounds responded to all the reactions expected of di-thenhydroxamic acid.<sup>48</sup> They both formed salts; neither one gave a color test with ferric chloride, but after hydrolysis both showed an intense purple color with this reagent. The purest sample of the high-melting form melted at 105–107°. Its isomer melted at 83–86°. Both were soluble in alcohol, in ethyl acetate, and in hot benzene. In water and in ligroin they were insoluble.

*Analyses.* (I) Low-melting modification; subs., 0.3339: N, 16.90 cc. (16.5° and 762.0 mm.); (II) high-melting modification; subs., 0.4288: N, 19.60 cc. (18.5° and 769.1 mm. (16°)). Calc. for  $C_{10}H_7O_2NS_2$ : N, 5.53. Found: (I) 5.90, (II) 5.35.

*Potassium Salt.*  $C_4H_5S.CO.NK-O.CO.C_4H_5S$ .—The salts were all prepared from di-thenhydroxamic acid melting at 102–104°. In a small tube, the temperature of decomposition of the potassium salt was 122°.

*Analysis.* Subs., 0.1988:  $K_2SO_4$ , 0.0584. Calc. for  $C_{10}H_7O_2NS_2K$ : K, 13.42. Found: 13.18.

*Sodium Salt.*—There was no evident alcoholysis, when this last was prepared at room temperature. At 142° the dry salt decomposed.

*Analysis.* Subs., 0.0797:  $Na_2SO_4$ , 0.0206. Calc. for  $C_{10}H_7O_2NS_2Na$ : Na, 8.36. Found: 8.37.

*Silver Salt.*—An abundant white precipitate of the silver salt of di-thenhydroxamic acid resulted when aqueous solutions of the potassium salt and silver nitrate were mixed. It decomposed at 155°.

*Analysis.* Subs., 0.1253: Ag, 0.0376. Calc. for  $C_{10}H_7O_2NS_2Ag$ : Ag, 29.96. Found: 30.01.

When boiled with water, both the potassium and the sodium salts gave a dense precipitation of sym. di-thienyl urea. Water solutions of the pure salts did not readily undergo hydrolysis or rearrangement.

### 5. Benzhydroxamic Acid.

The new method of preparation of hydroxamic acids, (see p. 2430) namely, by the use of the acid chloride in benzene, was successfully employed in the preparation of benzhydroxamic acid from benzoyl chloride.

*First Method.*—Six and five-tenths g. of benzoyl chloride was dissolved in 70 cc. of dry benzene. Upon the addition of 3.3 g. of free hydroxylamine a dense precipitate of benzhydroxamic acid was formed. The reaction mixture was shaken vigorously,

<sup>48</sup> Lossen, *Ann.*, 281, 289 (1894).

and then set aside for a few hours until the odor of benzoyl chloride had disappeared. Less than half a gram of benzhydroxamic acid was recovered from the benzene filtrate. One recrystallization of the solid from hot toluene removed hydroxylammonium chloride and yielded a pure product, m. p. 124°. This is identical with the material described by Lossen.<sup>30</sup> No evidence of the higher melting di-benzhydroxamic acid was observed.

**Second Method.**—Benzhydroxamic acid was also prepared in excellent yields, from benzoyl chloride, dissolved in organic solvents, with hydroxylammonium chloride instead of free hydroxylamine. An intimate mixture of anhydrous sodium carbonate (2.1 g.) and hydroxylammonium chloride (1.4 g.) was suspended in 50 cc. of ether. When 2.8 g. of benzoyl chloride was added there was little action, but it became more vigorous when 3.5 cc. of water was added. In about half an hour the reaction was complete. The ether solution was filtered into a distilling flask, and most of the solvent was removed. When this residue was cooled, an abundant crystalline mass precipitated. This was filtered, washed with a little ether, and pressed upon a porous plate. The benzhydroxamic acid melted at 124–125° without further purification. Yield, nearly quantitative.

Similarly, benzhydroxamic acid was obtained in quantitative yields when pyridine was substituted for sodium carbonate. Benzene was used instead of ether in this case.

**Thenoyl Ester of Benzhydroxamic Acid,  $C_6H_5.CO.NH.O.CO.C_4H_9S$ .**—Two and a half g. of benzhydroxamic acid dissolved in 25 cc. of water was neutralized with 0.7 g. of potassium hydroxide. Three portions of 1 g. each of thenoyl chloride were added to this solution. The precipitate was filtered, and washed with water; yield, 2 g. When it was recrystallized from ethyl acetate, it gave white needles which melted at 133.0–133.5°. The ester is soluble in alcohol, in acetone, in ethyl acetate and in hot benzene. It is insoluble in cold benzene, in ligroin and in water.

**Analysis.** Subs., 0.1547: N, 7.70 cc. (over 40% KOH at 15° and 763 mm.). Calc. for  $C_{12}H_9O_2NS$ : N, 5.67. Found: 5.85.

**Potassium Salt.  $C_6H_5.CO.NK.O.CO.C_4H_9S$ .**—When 0.32 g. of the thenoyl ester was dissolved in a mixture of 2 cc. of alcohol and 1 cc. of ether, the potassium salt was precipitated by the addition of 0.7 cc. of an alcoholic solution of potassium hydroxide (0.08 g. KOH). Five cc. of ether caused further precipitation.

A water solution of this salt became turbid in a short time, when left at room temperature. When the solution was boiled, a crystalline precipitate of *sym.* diphenyl urea, m. p. 236–238°, was formed.

The dry potassium salt puffed vigorously at 135–140°, providing the tube containing it was thrust into a bath previously heated to that temperature. However, when the tube was gradually warmed, a mild decomposition took place. There was no noticeable action until 160°, although phenyl isocyanate was undoubtedly being evolved at a temperature somewhat below that.

**Analysis.** Subs., 0.1788:  $K_2SO_4$ , 0.0538. Calc. for  $C_{12}H_9O_2NSK$ : K, 13.70. Found: 13.50.

**Silver Salt.**—When silver nitrate, in water solution, was added to a solution of the potassium salt in water, a voluminous white precipitate of the silver salt resulted. It blackened near 165°.

**Analysis.** Subs., 0.0897; Ag, 0.0274. Calc. for  $C_{12}H_9O_2NSAg$ : Ag, 30.47. Found: 30.54.

### Summary.

An interpretation of the mechanism of the Beckmann rearrangement has been proposed, based upon the modern conception of chemical bonds

and electrons. The transfer of electrons for all stages in the process has been pictured in a detailed manner.

The following hypothesis has been advanced: the relative ease of rearrangements of the Beckmann type is dependent upon the tendency for the radical R in the univalent nitrogen derivative, *e. g.*, (R.CO.N), to exist as a free radical.

The hypothesis was tested successfully with the sodium and the potassium salts of the acyl esters both of diphenylacethydroxamic acid and of triphenylacethydroxamic acid. Rearrangement of the salts in solution was found to be more reliable for purposes of comparison than rearrangement of the solid salts. In agreement with the hypothesis, the relative ease of rearrangement was greater with triphenylacethydroxamic acid derivatives than with the similar compounds in the diphenyl series. When water solutions of the salts in the triphenyl series were heated, the product of rearrangement was triphenylmethyl isocyanate, and not *sym.* bi-triphenylmethyl urea. This is a singular fact. The phenomenon of chromo-isomerism was displayed by the silver salts of the diphenyl series, as well as those of the triphenyl series.

Diphenyl ketene and hydroxylamine were found to react readily in a neutral solvent to form diphenylacethydroxamic acid. Modifications of this new reaction between ketenes and hydroxylamine, or substituted hydroxylamines, should be valuable in future synthetic work.

The properties of pyromucyl-hydroxamic acid, and of  $\alpha$ -thenhydroxamic acid have been determined. The latter resembles benzhydroxamic acid very closely. The former is similar to benzhydroxamic acid in many respects, but its derivatives differ materially in rearrangement. These two compounds, which are representatives of the furane and of the thiophene types, prepare the way for further investigations of heterocyclic hydroxamic acids.

ACTION OF ARSENIUS CHLORIDE ON ANILINE.<sup>1</sup>

BY JOHN H. SCHMIDT.

Received July 14, 1921.

## Introduction.

The action of arsenious chloride upon aniline has been studied by a number of investigators, each of whom has obtained different results. The reaction was first investigated by Schiff,<sup>2</sup> who described compounds resulting from the direct action of arsenious chloride and iodide on aniline, to which he assigned the formulas,  $\text{As} \equiv (\text{NHC}_6\text{H}_5\text{HCl})_3$  and  $\text{As} \equiv (\text{NHC}_6\text{H}_5\text{HI})_3$ . Leeds<sup>3</sup> obtained somewhat similar results, while Landau<sup>4</sup> allowed arsenious chloride to react with aniline in benzene solution and obtained a compound to which he assigned the formula:  $\text{AsCl}_3 + 4(\text{C}_6\text{H}_5\text{NH}_2) + \text{H}_2\text{O}$ . Anschütz and Meyer<sup>5</sup> were unable to obtain a compound corresponding to the one described by Schiff, and state that the third halogen of arsenic halide is not replaceable by aniline. They also show that the compounds described by Landau were probably nothing more than impure mixtures. They isolated two compounds, however, to which they assign the formulas,  $\text{As}(\text{NHC}_6\text{H}_5)_2\text{Cl}_2$  and  $\text{As}(\text{NHC}_6\text{H}_5)_2\text{Cl}$ , and the corresponding arsenanilide dimethyl and diethyl esters.

More recently Morgan and Micklethwait<sup>6</sup> describe a condensation product obtained by adding arsenious chloride to aniline in benzene solution. They assign to this compound either of the two formulas,  $\text{C}_6\text{H}_5\text{NHC}_6\text{H}_4\text{As}(\text{C}_6\text{H}_4\text{NH}_2)_2$ , or  $\text{C}_6\text{H}_5\text{NHC}_6\text{H}_4\text{As}(\text{NHC}_6\text{H}_5)_2\text{C}_6\text{H}_5\text{NH}_2$ .

Substituted anilines have been more thoroughly investigated. Michaelis and Rabinerson<sup>7</sup> found that dimethyl- and diethyl-aniline contain a reactive hydrogen atom readily replaceable by an arsenic radical, and in this manner prepared a number of substituted arsanilic acids.

In this research a study has been made of the action of arsenious chloride on aniline in *n*-heptane solution, with the result that a yellow granular substance was obtained, which could be purified by vacuum sublimation. This was apparently similar to Schiff's compound, except that it had a much higher melting point. The product showed interesting decomposition reactions, being transformed readily by heating it, either alone or preferably with an excess of aniline, into cyclic arsenic compounds.<sup>8</sup> The

<sup>8</sup> This work was completed previous to the publication by Wieland and Rheinheimer, *Ann.*, 423, 1 (1921), on the preparation of similar condensation products obtained by the condensation of diphenylamine and arsenious chloride.

following equations probably indicate this transformation.

Chloro-phenarsazine, to which Formula I has been assigned, has been previously prepared<sup>9</sup> by the action of arsenious chloride on diphenylamine.

Phenarsazine oxide was found to yield on oxidation the corresponding arsonic acid, (II) and on nitration a dinitro-arsonic acid (III). The latter

compound may evidently exist in two tautomeric modifications, which may be represented as follows.

<sup>9</sup> Ger. pat. 281,049; *Centr.*, 86, 72 (1915).

This would satisfactorily explain the intense red color of alkaline solutions of the nitro compound. Further proof for this assumption has been obtained by the isolation of a di-sodium salt (IV) of the nitro derivative.

The study of the reaction of arsenious chloride and aniline was undertaken originally in an attempt to prepare "arsanilide," a substance which should be formed as an intermediate in the preparation of arsanilic acid by the reaction of aniline and arsenic acid according to the following equations.

The preparation of both a mono-aniline and di-aniline arsenate was easily accomplished, but it was found impossible to transform the former into an "arsanilide."

### Experimental.

**Trianiline-arsine Hydrochloride.**—The heptane<sup>10</sup> used was purified according to the method of Sher<sup>11</sup> and dried over sodium. The aniline used was twice distilled and dried over sodium hydroxide. The arsenious chloride was a pure commercial material and not further purified.

Nine cc. of arsenious chloride (18 g. or  $\frac{1}{3}$  mol) was added to 100 cc. of heptane contained in a large test-tube fitted with a mechanical stirrer and dropping funnel. The test-tube was kept well surrounded with ice. To the heptane solution of arsenious chloride 31 cc. of aniline ( $\frac{1}{3}$  mol plus a slight excess) was slowly added with stirring. Immediate precipitation of a yellow granular compound occurred. After the complete addition of the aniline, stirring was continued for 15 minutes more and the reaction mixture then rapidly filtered with suction. The crude product was dried in a vacuum at 100°, since it holds heptane very tenaciously.

The ease with which the compound underwent decomposition and its insolubility in the common inert solvents (acetone, ether, benzene, and chloroform) made it extremely difficult to purify. Distillation in a vacuum was impractical, since the dis-

<sup>10</sup> The heptane was kindly furnished by Dr. Kremers, Director of the Pharmacy Department, University of Wisconsin.

<sup>11</sup> Sher<sup>11</sup>, *Thesis*, University of Wisconsin, 1918.

tillate adheres so tenaciously to the receiver that it was often necessary to break the flask to obtain the product. Purification was finally effected by vacuum sublimation.

Fig. 1.

An apparatus was designed for this purpose, which is shown in Fig. 1. It consisted of a Beckmann boiling-point apparatus, A, in which a water-cooled test-tube, B, was inserted to serve as a condenser. The substance to be sublimed was placed in the outer flask, A, which was heated by a metal bath. The sublimate condensed on tube B to which it adhered firmly and was easily removed without loss.

The purified compound is a light yellow, crystalline solid melting with some decomposition at 148–150°, which is 60° higher than the melting point assigned to the compound isolated by Schiff. It is readily decomposed by water and absolute alcohol, dissolving in them to a clear solution when heated, but on cooling a mixture of arsenious oxide and aniline hydrochloride crystallizes out. The product undergoes oxidation on exposure to air and, unless immediately analyzed, gives somewhat low results for arsenic. Arsenic was determined

by the method of Little, Cahen and Morgan,<sup>12</sup> chlorine by Stepanow's<sup>13</sup> method, and nitrogen by the Kjeldahl-Gunning method.

**Analyses.** Calc. for  $C_{13}H_{21}N_3Cl_2As$ : N, 9.13; Cl, 23.10; As, 16.30. Found: N, 9.25, 9.21; Cl, 23.15, 23.00; As, 15.74, 15.75, 15.55.

**Phenarsazine Oxide.**—Five hundred cc. of dry redistilled aniline was placed in a 1-liter flask fitted with a dropping funnel and a reflux air condenser; 180 g. or 90 cc. of arsenious chloride was then added through the dropping funnel, a yellow precipitate of tri-aniline arsine hydrochloride being formed. On heating, the precipitate dissolved, the solution slowly darkening until finally it was deep purple in color. The temperature was slowly raised to the boiling point and boiling continued for 72 hours. While still hot the solution was poured into a 3-liter flask and 500 cc. of hot water carefully added. On cooling, the solution was made alkaline with sodium carbonate and the excess of aniline distilled with steam, the distillate being strongly alkaline, due to the ammonia formed in the reaction. The solution remaining in the flask was filtered away from the dark green powder which was washed several times with hot water, then with acetone and then again with hot water. This effectually removed the greater part of the impurities formed with the compound. For final purification it was recrystallized thrice from 80% acetic acid. When pure the compound was a pale yellow, crystalline solid, melting above 300°. The dry powder was extremely irritating to the membranes of the nose and mouth. The oxide was insoluble in alcohol, acetone, benzene, chloroform, ether, alkalis and dilute acids, but soluble in acetic acid and conc. sulfuric acid. The solution in sulfuric acid was deep purple in color, turning green upon addition of a trace of nitric acid. Water precipitated the original compound from its sulfuric acid solution. Yield of crude product, 70%. Analysis gave the following results, the arsenic and nitrogen being determined as in the previous experi-

<sup>12</sup> Little, Cahen and Morgan, *J. Chem. Soc.*, 109, 1356 (1916).

<sup>13</sup> Stepanow, *Ber.*, 39, 4056 (1906).

ment, while combustion of the substance for determination of carbon and hydrogen was carried out in a tube filled with granulated lead chromate.

*Analyses.* Calc. for  $C_{12}H_{11}ON_2As_2$ : C, 57.60; H, 3.60; N, 5.60; As, 30.00. Found: C, 58.2, 58.09; H, 3.85, 3.57; N, 5.70, 5.74; As, 30.19, 30.05.

**Phenazarsonic Acid.**—Five g. of pure phenarsazine oxide was added to 100 cc. of water and 20 cc. of 15% sodium hydroxide solution. Ten to 20 cc. of perhydrol (30% hydrogen peroxide) was added and the mixture shaken and warmed until complete solution took place. The excess of hydrogen peroxide was decomposed by boiling, the solution filtered, cooled and acidified with acetic acid, the phenazarsonic acid being precipitated out. It was recrystallized from 50% acetic acid. It should be noted that pure phenarsazine oxide must be used, since certain impurities in the crude product completely prevent its oxidation by hydrogen peroxide. The pure product was a very pale yellow, crystalline solid, melting above  $300^\circ$ ; yield 85%. It was readily soluble in dilute alkalis, insoluble in acetone, ether and alcohol.

*Analyses.* Calc. for  $C_{12}H_{10}O_2NAs$ : C, 52.36; H, 3.63; N, 5.09; As, 27.27. Found: C, 52.87, 52.37; H, 3.63, 3.74; N, 4.30, 4.83; As, 26.81, 26.93.

**Dinitro-phenazarsonic Acid.**—Five g. of pure phenarsazine oxide was heated under a reflux condenser with a mixture of 300 cc. of nitric acid (1:2) and 40 cc. of acetic acid until complete solution took place. The hot solution was filtered through glass wool into 2 liters of cold water, the nitro derivative being immediately precipitated. The crude product was purified by dissolving it in hot dil. ammonium hydroxide, filtering and reprecipitating the nitro compound with dil. hydrochloric acid; yield 80%. The pure product was a bright yellow powder which decomposed with a bright flash on heating. It was readily soluble in alkalis, forming a deep red solution, but sparingly soluble in water and alcohol. Analysis gave the following results, the nitrogen being determined by the modified Kjeldahl method for determining nitrogen in nitro compounds. Combustion of the substance was very difficult due to its explosive nature, the difficulty being finally overcome by distributing the substance in small portions along the boat and using extreme care in heating it.

*Analyses.* Calc. for  $C_{12}H_8O_6N_2As$ : C, 39.45; H, 2.19; N, 11.50; As, 20.54. Found: C, 39.92, 39.89, 39.40; H, 2.42, 2.44, 2.21; N, 11.8, 11.5; As, 20.16, 20.20.

**The Sodium Salt of Dinitro-phenazarsonic Acid.**—Two g. of the nitro compound was dissolved in the required amount of 0.025 *N* alkali to form the disodium salt. The solution was concentrated to a small volume on the water-bath, and on cooling the sodium salt crystallized out. It was recrystallized twice from alcohol, the pure product being a yellow crystalline solid, readily soluble in water, soluble in hot alcohol to form a bright red solution, but less soluble in the cold.

*Analyses.* Calc. for  $C_{12}H_6O_6N_2AsNa_2$ : As, 18.34. Found: 18.63, 18.35.

**Mono-aniline Salt of Arsenic Acid.**—This was prepared by dissolving redistilled aniline in alcohol, adding to it an excess of sirupy arsenic acid and warming until the aniline arsenate was in solution. On cooling, the mono-aniline salt crystallized in fine pearly leaflets. It was twice recrystallized from alcohol; m. p.,  $147-148^\circ$ . Arsenic was determined by Ewins<sup>14</sup> method and nitrogen by the Kjeldahl-Gunning method.

*Analyses.* Calc. for  $C_6H_7O_4NAs$ : N, 5.95; As, 31.91. Found: N, 6.22, 6.23; As, 31.67, 31.89.

Unsuccessful attempts were made to convert this salt into an "arsanilide" by heating it in either nitrobenzene, chlorobenzene or xylene. The use of dehydrating agents such as calcium oxide and copper sulfate also failed to give the desired result.

<sup>14</sup> Ewins, *J. Chem. Soc.*, 109, 1356 (1916).

**Di-aniline Salt of Arsenic Acid.**—This was prepared by dissolving sirupy arsenic acid in alcohol, adding to it an excess of aniline and warming until the di-aniline salt was in solution. On cooling, it crystallized in pearly leaflets; *m. p.*, 143°.

*Analyses.* Calc. for  $C_{12}H_{17}O_4N_2As$ : N, 8.53; As, 22.86. Found: N, 8.11, 8.10; As, 23.23, 23.32.

### Summary.

1. The reaction between aniline and arsenious chloride has been studied and a new method for the preparation of secondary arsonic acid derivatives devised.

2. Tri-aniline-arsine hydrochloride has been prepared in a pure state and its properties described.

3. Several new compounds, phenarsazine oxide, phenazine-arsonic acid, dinitro-phenazine-arsonic acid, and disodium dinitro-phenazine-arsonic acid have been prepared and their methods of preparation and properties described.

4. A new vacuum sublimation apparatus has been described.

5. Directions for the preparation of mono-aniline and di-aniline salts of arsenic acid have been given.

The writer wishes to express his gratitude to Professor Richard Fischer, under whose direction this work has been carried out, and also to Professors Loevenhart and Kremers, for their interest in this research.

MADISON, WISCONSIN.

No. 374.]

## EFFECT OF CERTAIN ANTISEPTICS UPON THE ACTIVITY OF AMYLASES.

BY H. C. SHERMAN AND MARGUERITE WAYMAN.

Received July 22, 1921.

In experimental studies of enzyme action, antiseptics are frequently used to prevent or suppress any activities of microorganisms. It is obviously important to know as definitely as possible whether antiseptics can be thus used without influence upon the activity of the enzyme which it is desired to study; and furthermore we may hope that a systematic determination of the behavior of enzymes toward antiseptics of different types may ultimately throw light upon the chemical nature of the enzymes themselves and the discussion of enzyme dispersions in terms of colloid chemistry.

The experiments here recorded have to do with the influence of toluene, formaldehyde, and copper sulfate upon amylases of both animal and vegetable origin and when tested in both natural and purified form. The literature affords many statements of a general nature regarding the relation of antiseptics to enzyme action, usually giving the impression that

those of the type of toluene or chloroform have little if any influence upon enzymes while such antiseptics as formaldehyde and copper sulfate are more likely to prove injurious. Precise statements accompanied by experimental evidence appear to be few.

Chittenden and Painter<sup>1</sup> in the course of a study of the effects of numerous salts upon saliva, found copper sulfate to be very injurious to its starch-digesting action.

Grützner and Wachsmann<sup>2</sup> reported that ether, chloroform and thymol retard the action of pancreatic amylase, chloroform being the most destructive of the three.

Kopaczewski<sup>3</sup> could observe no effect of chloroform or toluene in a concentration of 0.1% upon the action of takadiastase, which action, however, was prevented by 1.0% formaldehyde.

Myers and Scott<sup>4</sup> found salivary amylase to be relatively stable in the presence of chloroform, toluene or thymol, toluene appearing to preserve the activity of the enzyme the best of these three antiseptics.

Bokorny<sup>5</sup> reported that maltase was injured by 0.1%, and destroyed by 1% of formaldehyde.

**Materials and Methods.**—The amylase preparations employed in this investigation consisted of: (1) commercial pancreatin, Lab. No. 8; (2) purified pancreatic amylase, preparations T-8-B, T-18-A, T-18-B made as described in a previous paper<sup>6</sup> and having amylolytic powers of about 3000 according to the method and scale in use in this laboratory since 1910;<sup>7</sup> (3) human saliva as secreted; (4) malt extract; (5) purified malt amylase, Lab. No. 151, amylolytic power<sup>7</sup> 1274; (6) takadiastase, commercial; (7) the purified amylase of *Aspergillus oryzae* prepared from takadiastase and having about 30 times its amylolytic power. We are indebted to Parke, Davis and Company for the pancreatin and takadiastase used.

The starch, water, and other materials employed were purified as described in previous papers from this laboratory.

The purest obtainable chloroform, toluene, copper sulfate, and formaldehyde were employed. The percentage strength of the last substance was determined by the peroxide method.

The plan of experimentation was to allow a suitable amount of an amylase solution to act upon 100 cc. of 2 % starch paste with and without the antiseptic to be tested in the presence of suitable "activating" salts for 30 minutes at 40° in the same manner as for the determination of diastatic power by the gravimetric method of Sherman, Kendall and Clark,<sup>7</sup> the reducing

sugar formed by the action of the amylase upon the starch being estimated by heating with an excess of Fehling solution and the result expressed in terms of mg. of cuprous oxide reduced, allowance being made for the reduction resulting from the starch alone or the starch plus antiseptics as determined by blank tests.

### Experiments with Toluene.

Of the antiseptics of the "lipoid solvent" type, the ones most commonly used in enzyme work are chloroform and toluene. Preliminary experiments indicated that chloroform at a concentration of 0.0000124 *M* measurably diminished the action of purified pancreatic or malt amylase but not of a simple malt extract. Chloroform, however, did not lend itself readily to experimentation by the method here used because of its reducing effect upon Fehling solution. Since chloroform and toluene are so largely used interchangeably in work with enzymes and toluene does not appreciably influence the reduction of Fehling solution, it was chosen in preference to chloroform for the following series of experiments. In testing its influence upon the enzyme, 5 cc. of toluene was shaken with the 100 cc. of digestion mixture and the insoluble surplus allowed to remain upon the surface of the substrate.

The results of parallel determinations with and without toluene are shown in Table I.

TABLE I.  
EFFECT OF TOLUENE UPON VARIOUS AMYLASES.

Enzyme.			Reduction of $\text{Cu}_2\text{O}$ .		Loss of Activity.
Kind.	Amount. Mg.	No $\text{C}_7\text{H}_8$ . Mg.	5 cc. $\text{C}_7\text{H}_8$ . Mg.		%.
Commercial pancreatin, No. 8....	0.96	333.6	331.8		?
Purified pancreatic amylase, No.					
T 18A .....	0.05	200.7	191.0		5
Saliva.....	0.06 cc.	201.7	194.5		4
Malt extract.....	0.035 cc.	238.4	216.0		9
Purified malt amylase, No. 151..	0.15	329.6	304.7		8
Commercial takadiastase, No. 7.	5	308.6	304.4		1
Aspergillus amylase, No. 22b ...	0.25	293.4	285.9		3

From these results it appears that commercial pancreatin and takadiastase were influenced to only a negligible extent if at all by the saturation of the digestion mixture with toluene, while saliva, malt extract and the purified amylase preparations were measurably inhibited in their action, but not inactivated to any very serious extent. This is in accordance with the results of a previous series of experiments carried out by Miss Jennie A. Walker and one of us, in which the action of purified malt amylase was repeatedly found to be slightly diminished by the presence of toluene, but to an extent little if any greater than the variations to be expected between duplicate experiments with such enzyme preparations.

able loss of activity of commercial pancreatin and that the loss increased regularly with the concentration of the formaldehyde. Because of the reduction of Fehling's solution by the formaldehyde itself, it was not feasible to carry these experiments to a higher concentration than approximately 0.00017 *M*.

In order to see whether the concentration of the enzyme solution made any difference in the amount of inhibition caused by 10 cc. of formaldehyde solution, 0.4 cc., 0.6 cc., and 0.8 cc. of the enzyme solution were used. The results are given in Table III.

TABLE III.

EFFECT OF FORMALDEHYDE UPON VARIOUS CONCENTRATIONS OF PANCREATIN.

Cc.	Pancreatin. Mg.	Reduction of $\text{Cu}_2\text{O}$ .		10 cc. (0.000116 <i>M</i> ). Mg.	Loss of Activity. %.
		No HCHO.	Mg.		
0.4	0.48	132.3		110.0	17
0.6	0.72	204.4		166.8	18
0.8	0.96	269.4		218.5	19

According to these results, it made practically no difference in the percentage of retardation whether 0.48 mg., 0.72 mg., or 0.96 mg. was used with 2% starch paste in the presence of 10 cc. of formaldehyde solution.

To see whether the concentration of starch affected the result, 1%, 2%, and 4% starch pastes were used with 0.96 mg. of commercial pancreatin in the presence and absence of formaldehyde. The results are shown in Table IV.

TABLE IV.

EFFECT OF FORMALDEHYDE UPON THE ACTION OF PANCREATIN ON DIFFERENT CONCENTRATIONS OF STARCH.

Conc. of Starch. %.	Reduction of $\text{Cu}_2\text{O}$ .		Loss of Activity. %.
	No HCHO. Mg.	10 cc. (0.000116 <i>M</i> ). Mg.	
1	222.8	173.9	22
2	259.1	208.5	20
4	277.5	228.2	18

The percentage of destruction did not vary much no matter whether 1%, 2% or 4% starch was used.

From Tables II to IV it can be seen that the percentage loss of activity of commercial pancreatin depends not upon the concentration of the enzyme or the concentration of the substrate, but only upon the concentration of the antiseptic.

### Experiments with Copper Sulfate.

A 0.00056 *M* copper sulfate solution was prepared, and 5 cc., 10 cc. and 15 cc. of this solution used in the experiments. The results are given in Table V.

TABLE V.  
EFFECT OF COPPER SULFATE UPON VARIOUS AMYLASES.

Kind.	Enzyme.	Amount.	Cu <sub>2</sub> O.				Loss of Activity.			
			No CuSO <sub>4</sub> .	5 cc. CuSO <sub>4</sub> (0.000028 M)	10 cc. CuSO <sub>4</sub> (0.000056 M)	15 cc. CuSO <sub>4</sub> (0.000084 M)	5 cc. CuSO <sub>4</sub> (0.000028 M)	10 cc. CuSO <sub>4</sub> (0.000056 M)	15 cc. CuSO <sub>4</sub> (0.000084 M)	
			Mg.	Mg.	Mg.	Mg.	%.	%.	%.	
Comm. pancreatin, No. 8.....		0.96	278.7	82.7	71.2	62.8	70	74	77	
Pur. pancreatic amylase, No. T 18B.....		0.07	206.6	51.4	48.0	43.0	75	77	79	
Saliva.....		0.66 cc.	267.1	170.3	167.3	166.8	36	37	38	
Malt extract.....		0.035 cc.	245.9	215.6	189.1	166.5	12	23	32	
Pur. malt amylase, No. 151 ....		0.15	342.6	322.2	306.8	296.2	6	10	14	
Comm. takadiastase, No. 7.....		5.00	303.8	291.5	277.6	266.3	4	9	12	
Aspergillus amylase, No. 22b...		0.25	279.0	257.9	241.9	232.0	8	13	17	

The results in Table V show that all of the amylases studied were affected by from 0.000028 *M* to 0.000084 *M* copper sulfate. The pancreatic and salivary amylases were affected considerably more than malt amylase and takadiastase.

Assuming that the iso-electric points of the amylase proteins are in the range of other proteins previously reported by Loeb and others, namely in the vicinity of  $C_H^+ 10^{-5}$ , and since the activity of the pancreatic amylase was measured in the presence of electrolytes at a reaction of about  $C_H^+ 10^{-7}$  while the reaction of the substrate solutions in the cases of malt amylase and takadiastase was about  $C_H^+ 10^{-4.5}$ , it would appear that the greater destruction of pancreatic amylase may be due to the formation of insoluble copper-proteinates<sup>3</sup> which would form at the hydrogen-ion concentration of the substrate solution as prepared for the pancreatic, but not as prepared for the malt and aspergillus amylases. We hope soon to study the iso-electric points of some of these amylase preparations.

Saliva was affected only about half as much as was the pancreatic amylase. This may be due to the presence in the saliva of a relatively large amount of other protein which would tend to protect the amylase by removing copper in the manner suggested above.

The results of a second series of experiments with a new solution of copper sulfate, used in such amounts as to give a wider range of final concentrations than in those above described, are shown in Table VI.

It may be seen from Table VI that in the presence of exceedingly minute amounts of copper sulfate its inhibitory effect is much more pronounced in the case of the pancreatic than of the malt amylase. In all cases the percentage loss of activity increases with increasing concentration of copper. Purified pancreatic amylase was tested with somewhat larger amounts

<sup>3</sup> Loeb, *J. Gen. Physiol.* 1918-19, *passim*.

TABLE VI.  
EFFECT OF COPPER SULFATE UPON CERTAIN AMYLASES.

Pur. malt amylase, No. 151.....		0.15	308.4	308.2	279.9	199.5	..	9	35

than in the above experiments with the result that copper sulfate at 0.00042 *M* was found to deprive it of 89% of its activity; and at 0.00054 *M*, 92% of the activity was lost.

Experiments with various concentrations of enzyme (pancreatin) and of starch, similar to those described under formaldehyde, were performed with copper sulfate.

The results are shown in Tables VII and VIII.

TABLE VII.  
EFFECT OF COPPER SULFATE WITH VARIOUS CONCENTRATIONS OF PANCREATIN.

Cc. Pancreatin.	Mg.	Reduction of Cu <sub>2</sub> O.		Loss of Activity.
		No CuSO <sub>4</sub> .	10 cc. (0.00006 M).	
		Mg.	Mg.	%.
0.4	0.48	140.5	36.3	74
0.6	0.72	204.8	55.7	73
0.8	0.96	280.9	74.5	74

TABLE VIII.  
EFFECT OF COPPER SULFATE UPON THE ACTION OF PANCREATIN ON STARCH AT DIFFERENT CONCENTRATIONS.

Conc. of Starch.	Reduction of Cu <sub>2</sub> O.		Loss of Activity.
	No CuSO <sub>4</sub> .	10 cc. (0.00006 M).	
%.	Mg.	Mg.	%.
1	240.8	71.1	70
2	276.8	79.0	71
4	290.3	88.8	69

From Tables VII and VIII it will be observed that the percentage of loss of activity of pancreatin is practically unaffected by a change in enzyme concentration or by a change in the starch concentration. It is not the ratio of antiseptic to enzyme or of antiseptic to substrate, but the ratio of antiseptic to water which determines the activity of the amylase.

### Summary.

Low concentrations of chloroform did not affect commercial pancreatin or malt extract, but did affect the purified preparations of these amylases.

Toluene had very little influence upon the activities of the amylases either in their natural or purified condition.

Commercial pancreatin, purified pancreatic amylase, saliva, malt extract, purified malt amylase, commercial takadiastase, and the purified amylase of *Aspergillus oryzae* were all injured by formaldehyde even in small amounts. Takadiastase was the least, and purified pancreatic amylase the most, affected. The percentage of loss of the enzyme action increased in all cases with increasing concentration of formaldehyde.

A very low concentration of formaldehyde (0.0000116 *M*) gave a 3% destruction of the activity of commercial pancreatin.

All of the enzymes studied were very sensitive to copper sulfate. Pancreatic amylase was much more sensitive than any of the others. Most of the enzymes were injured by as low a concentration of copper sulfate as 0.000006 *M*. Almost complete destruction of the activity of purified pancreatic amylase was caused by 0.00054 *M* copper sulfate. The inhibiting effect of copper sulfate on the activity of amylases increased with increasing concentration of copper sulfate.

The percentage loss of enzyme action due to formaldehyde and to copper sulfate solution did not depend upon the ratio of antiseptic to enzyme or of antiseptic to substrate, but upon the ratio of antiseptic to water, or the concentration of the antiseptic in the system.

The results demonstrate the need of attention to the possible effects of antiseptic upon enzyme in cases in which antiseptics are used to suppress microorganisms in studies of enzyme activity.

The much greater sensitiveness of the amylases to formaldehyde and copper sulfate than to toluene is of further interest in connection with the problem of the protein nature of these enzymes.

We are indebted to the Carnegie Institution of Washington for the use of enzyme preparations which had been purified in connection with work done under the auspices of the Institution.

## THE INFLUENCE OF CERTAIN AMINO ACIDS UPON THE ENZYMIC HYDROLYSIS OF STARCH.

BY H. C. SHERMAN AND FLORENCE WALKER.

Received July 22, 1921.

Our experiments on the influence of amino acids upon the rate of hydrolysis of starch by different enzymes, begun with the study of asparagine and aspartic acid,<sup>1</sup> have been extended to glycine, alanine, tyrosine and phenylalanine. Essentially the same experimental methods have been employed as in our work with asparagine and aspartic acid. In the experiments described below, however, "soluble" starch, prepared by the Lintner

<sup>1</sup> Sherman and Walker, *THIS JOURNAL*, **41**, 1867 (1919).

method and further purified by washing 9 times with ordinary distilled and 6 times with specially purified thrice distilled water, has in all cases been used as substrate. The amino acids here used were imported. The amylase preparations and other enzyme-containing materials tested were (1) pancreatic amylase preparations Nos. 58, 59, 60, 77B and 81B, (2) commercial pancreatin No. 8, (3) malt amylase preparation No. 155, (4) malt extract, (5) aspergillus amylase preparations Nos. 22, 22b, and 23, (6) commercial takadiastase, and (7) fresh saliva. Thrice distilled water was used for making starch dispersions, solutions of activators, enzymes, etc., and for rinsing all glassware.

**Method.**—The method<sup>2</sup> of testing the influence of the amino acids is briefly as follows. An amount of air-dry starch equivalent to the required amount of anhydrous material is weighed out, mixed with a little cold water, dispersed by pouring into boiling water (about 80 cc. per g. of starch) and boiled for about 3 minutes. This is transferred to 100cc. cylinders, neutralized with 0.01 *N* sodium hydroxide solution and the salts most favorable for the action of the amylase<sup>3</sup> added. The dispersions are then made up to 100 cc. so that the concentration of starch is exactly 1%, mixed thoroughly by stirring and placed in the 40° bath to reach the desired temperature. In the meantime, the enzyme solution is prepared and the required amount pipetted into dry flasks. The starch dispersions are then poured into the flasks containing the enzyme at intervals of 15 seconds and the flasks placed in the 40° bath. At the end of 30 minutes, enzymic action is stopped by pouring 50 cc. of Fehling solution into the digestion mixtures, at intervals of 15 seconds and in the same order in which the starch was poured on the enzyme. The amount of reducing sugar formed is determined by immersing the flasks in a boiling water bath for 15 minutes. The cuprous oxide is filtered into weighed Gooch crucibles, washed with hot water, alcohol and ether, dried at 100°, and weighed. Glycine and alanine being quite soluble were dissolved in a small volume of water and added to the starch paste, after it was poured into the cylinders and before being made up to volume. Since tyrosine and phenylalanine are difficultly soluble, the amount of each used was added to the water in which the starch was dispersed and boiled with it. To show whether this variation in procedure affected the action of the amino acid on the enzyme, digestions were carried out in which equal amounts of asparagine were added before boiling in some cases and after cooling in others. Activation due to asparagine was the same in both cases. The same test was made with aspartic acid with the same result.

<sup>2</sup> Sherman, Kendall and Clark, *THIS JOURNAL*, 32, 1082 (1910).

<sup>3</sup> Sherman, Thomas and Baldwin, *ibid.*, 41, 231 (1919). Pending further investigation the substrate is prepared in the same manner for the action of saliva as for pancreatic amylase.

In these experiments the amino acids were made neutral to rosolic acid with 0.01 *N* sodium hydroxide solution.

### Measurement of the Influence of Different Amino Acids.

Tables I-IV show the influence of carefully neutralized glycine, alanine, tyrosine and phenylalanine, added separately and in combination with a second amino acid, upon the rate of hydrolysis of "soluble starch" by different enzymes. The reducing sugar formed by enzymic hydrolysis is chiefly maltose, but since small amounts of glucose may also be present the results are stated in terms of the weight of cuprous oxide resulting from the reduction of the Fehling solution by the sugar or sugars present. The amounts of enzyme used in the experiments were so regulated as to result in the transformation of about 1/5 of the starch into sugar.

Activation due to phenylalanine		36	14	18	12	6	11	5

The data given in the above tables show an undoubted increase in the activity of purified pancreatic amylase, pancreatin, saliva, and purified malt amylase in the presence of any one of the 4 amino acids investigated or of any 2 of them whose joint effects were tested. The apparent activation is not so marked in case of the less sensitive enzymes, malt extract, takadiastase and aspergillus amylase. It is also true that the acceleration of hydrolysis by the amino acids is somewhat greater for the purified form of the enzyme than for the natural or commercial material in which the enzyme is accompanied by other constituents of the tissue or secretion in question. It will be observed that, in general, the 4 amino acids here discussed as well as asparagine and aspartic acid previously studied<sup>1</sup> behave in a similar manner. The above results show no evidence that the addition of two amino acids to the same digestion mixture causes greater activation than would result from a corresponding concentration of one of them. The following combinations have been tested: aspartic acid and aspar-

agine, glycine and aspartic acid, tyrosine and asparagine, phenylalanine and asparagine, alanine and glycine.

Since some investigators have held that the activating effect of amino acids is attributable to their presence inducing a more favorable hydrogen-ion concentration in the digestion mixture, we have determined electrometrically the hydrogen-ion concentrations of our mixtures with and without neutralized amino acid, with the results shown in Table V. It is evident that the reaction of our mixtures is not changed by the addition of the neutralized amino acids to any significant degree and therefore that the favorable effect of the amino acid upon the enzyme action is due to some other cause or causes.

#### Mode of Action of the Amino Acid.

Several possible explanations of the favorable influence of the amino acids may be suggested.

(1) **Is the Action Direct?**—It is conceivable that the amino acid may directly facilitate the interaction of the enzyme with the substrate. Until our knowledge of the mechanism of enzyme action is further developed this suggestion, while the most direct, can only be approached by somewhat speculative discussion or, experimentally, by a process of elimination of other possibilities.

(2) **Does the Effect Depend upon Some Reaction with the Products of Digestion?**—Since the activity of an enzyme is often diminished by the accumulation of the products of its action, it might be suggested that the amino acids exert their favorable effect through combining with some product or products of the hydrolysis which might otherwise combine with the enzyme itself, thus reducing its activity, or might, if remaining free in the solution, tend to bring the hydrolysis to equilibrium. To test this point, the effect of the addition of 100 mg. of pure maltose to the starch paste, with and without glycine, on hydrolysis by pancreatic amylase was determined. Similar experiments in which a certain amount of a hydrolytic mixture was substituted for pure maltose were carried out as follows. One g. of starch was digested for 1 hour at 40° by pancreatic

amylase, at the end of which time the enzyme was destroyed by boiling. The effect of 25 and 50 cc. of this digested mixture on hydrolysis with and without glycine was tested. Correction being made for the reducing power of maltose or digestion products added, and the amounts of activating salts being properly adjusted, both pure maltose and the hydrolytic products of the starch were found under the conditions of these experiments to be without measurable effect upon the activity of the enzyme used, showing that the favorable influence of amino acids cannot be explained in this way.

(3) **Does the Amino Acid Protect the Enzyme against Some Accidental or Unknown Deleterious Influence?**—Aside from the possibility of correcting an unfavorable hydrogen-ion concentration which has already been excluded as an explanation of our results, it is possible that the amino acid may act by protecting the enzyme from some active but unknown deleterious influence. This is illustrated by the following experiments with cupric sulfate.

*Protective Action of Amino Acids Against Cupric Sulfate.*—These experiments were designed to show whether the deleterious effect upon amylase activity of such a heavy metal salt as copper sulfate could be wholly or in part overcome by the presence of an amino acid. In the experiments the results of which are given in Table VI, the cupric sulfate and amino acid were added to the cooled starch paste and thoroughly mixed before pouring onto the enzyme solution.

The above data show that a 0.00003 *M* concentration of cupric sulfate in the digestion mixture diminished the activity of pancreatic amylase by about 78%. This is in accordance with results recently obtained in this laboratory and reported in the preceding paper by Sherman and Wayman. However, upon the addition of 0.1% of amino acid, not only is the inhibiting influence of the cupric sulfate counteracted, but there is an increase in saccharification almost equal to that which occurs in the presence of amino acid and absence of copper. Further experiments were performed in which the cupric sulfate was added directly to the enzyme

solution in two concentrations, 0.0035 *M* and 0.00003 *M* and the efficiency of 0.1% glycine in the substrate in reactivating the enzyme was studied. Some results are given in Table VII.

TABLE VII.

REACTIVATION OF PANCREATIC AMYLASE BY GLYCINE AFTER INACTIVATION BY COPPER.

Glycine. Mg.	Conc. CuSO <sub>4</sub> in starch paste. <i>M</i> .	Conc. CuSO <sub>4</sub> in enzyme solution. <i>M</i> .	Conc. CuSO <sub>4</sub> in digestion mixture. <i>M</i> .	Cuprous oxide.

Numerous experiments showed that the inactivation of the enzyme by the copper and its reactivation by amino acid were considerably influenced by time and temperature. In Expt. 2 of Table VII the solution stood for about 12 minutes before testing; in Expt. 3 it stood for 55 minutes. The influence of temperature is illustrated in Table VIII.

As to the bearing of these experiments with cupric sulfate upon the question whether the role of amino acids is that of a direct accelerator of the enzyme action or rather that of a protector which increases the amount of work done by the enzyme through preventing its deterioration, it cannot be doubted that they establish the possibility of a very marked protective effect without precluding the additional possibility of a more direct action upon the enzyme.

Evidently with a low concentration of copper ions in solution these react with amino acid forming copper-amino ions<sup>4</sup> more readily than with the enzyme; and moreover, when the copper ion has already acted upon and inactivated a part of the enzyme, it apparently may still be taken up by the amino acid, and the enzyme thus freed from the copper may become active again.

(4) Does the Amino Acid Act by Retarding the Hydrolytic Destruction of the Enzyme?—Another possibility is that the amino acid may act

<sup>4</sup> See J. T. Barker, *Trans. Faraday Soc.*, 3, 188 (1908).

by preventing or retarding the deterioration of the enzyme in its aqueous solution. The very rapid deterioration of water solutions of pancreatic amylase, particularly when highly purified, and the influence of the sodium chloride and secondary phosphate (regularly used to "activate" this enzyme) in retarding the deterioration have been discussed in previous papers from this laboratory.<sup>5</sup> Since the deterioration of enzymic activity, while greatly retarded, is not entirely prevented by the presence of the salts, it is not improbable that the favorable influence of the amino acid may be due at least in part to a further protection of the enzyme from deterioration in the aqueous dispersion in which it acts.

This we have found to be the case, solutions of pancreatic amylase which had stood for 1 hour at 40° showing about 1/3 greater amylase activity when alanine had been added to the solution in advance. The conditions in this case were such as to result in greater deterioration than occurs in our ordinary tests of enzyme activity, both because of longer exposure of the enzyme to warm water and because it remained longer in water in the absence of its substrate. A series of similar experiments at different temperatures is now in progress, and the results thus far obtained go to show that the influence of the amino acid becomes more marked at the higher temperatures at which the enzyme is undergoing more rapid deterioration, thus strengthening the impression that the amino acid tends to preserve the enzyme from the destructive action of the water. Further discussion is best deferred until the completion of the projected series of experiments. Meantime, the now fully demonstrated fact that the presence of certain amino acids retards the deterioration of the enzyme constitutes an interesting addition to the evidence supporting the view that the enzyme itself is a substance of protein nature or which contains protein as an essential constituent.

### Summary.

Addition of glycine, alanine, phenylalanine or tyrosine caused an undoubted increase in the rate of hydrolysis of starch by purified pancreatic amylase, commercial pancreatin, saliva, or purified malt amylase. Less marked results were obtained with the less sensitive enzyme materials, malt extract, takadiastase, and an aspergillus amylase product prepared in the laboratory from takadiastase.

Each of the 4 amino acids here studied, as well as aspartic acid and asparagine previously investigated, showed a similar favorable influence upon the enzymic hydrolysis of the starch.

The addition of a mixture of two of these amino acids, produced no greater effect than would result from the same concentration of one of them. In these experiments the favorable effect of the added amino acid was

<sup>5</sup> Sherman and Schlesinger, *This Journal*, and in other papers of this series.

not due to any influence upon hydrogen-ion concentration nor to combination of the amino acid with the product of the enzymic reaction.

On the other hand it is shown that the addition of one of these amino acids is a very effective means of protecting the enzyme from the deleterious effect of cupric sulfate and may even serve to restore to full activity an enzyme which has been partially inactivated by copper.

The favorable influence of the amino acid is evidently due in part at least to a protection of the enzyme from deterioration in the aqueous dispersion in which it acts.

The establishment of the importance of the last mentioned factors does not preclude the possibility of a more direct influence of the amino acid upon the activity of the enzyme.

The investigation is being continued by studying the effects of the above amino acids through a wider range of times and temperatures and by extending the study to additional amino acids.

We are greatly indebted to the Carnegie Institution of Washington for grants in aid of this investigation.

## A STUDY OF THE INFLUENCE OF ARGININE, HISTIDINE, TRYPTOPHANE AND CYSTINE UPON THE HYDROLYSIS OF STARCH BY PURIFIED PANCREATIC AMYLASE.

By H. C. SHERMAN AND MARY L. CALDWELL.

Received July 22, 1921.

Previous work in this laboratory<sup>1</sup> having shown that various mono-amino acids tested exhibit quite uniformly the property of increasing the enzymic hydrolysis of starch, especially by pancreatic amylase, the experiments here described were planned to extend the investigation to amino acids of different types of structure.

Arginine and histidine solutions were prepared from casein and gelatin by Kossel's method<sup>2</sup> with slight modifications developed in the course of this work. In the latter part of the work commercial preparations<sup>3</sup> of histidine dichloride and tryptophane were also used. The cystine used was prepared by another worker in this laboratory.<sup>4</sup> In certain of the experiments we have also made use of glycine obtained commercially<sup>5</sup> and an imported phenylalanine.

The enzyme used was a pancreatic amylase preparation (No. T-19-B) purified

in this laboratory as previously described.<sup>6</sup> As substrate we used a commercial<sup>7</sup> "Soluble Starch according to Lintner" after purification by washing 9 times with distilled, and 6 times with thrice distilled, water. In weighing out portions of starch for test, allowance was made for its moisture content. Both the soluble starch to be used as substrate, and each amino acid to be tested, was titrated with 0.01 *N* sodium hydroxide solution or hydrochloric acid using rosolic acid as indicator. From the results of these titrations the amounts of 0.01 *N* alkali needed to neutralize the soluble starch, and of acid or alkali needed to neutralize each of the amino acids used, were calculated and these amounts were added to the starch dispersions and the amino acid solutions in preparing them for the experiments to be described. The hydrogen-ion concentrations of the starch pastes with and without the addition of the neutralized amino acid solutions were then verified by electrometric determinations and by the indicator method as explained below.

In the purification of all materials, and the cleaning and protection of all apparatus used in the experiments we have observed the precautions described in previous papers from this laboratory.

### Method.

Preliminary experiments showed that the gravimetric method worked out in this laboratory for determining the saccharogenic power of the enzyme<sup>8</sup> could not be used in the presence of arginine and histidine because of their interference with the determination of reducing sugar by Fehling solution. This had also been found to be true with cystine. For this reason the amylolytic power of the amylase was measured instead.

The procedure followed was based on the method of Wohlgemuth<sup>9</sup> and has been previously used and described in this laboratory.<sup>10</sup> Enough starch to make 600 cc. of a 1% starch paste was weighed out, mixed with 50 cc. of thrice distilled water and poured into 100 cc. of boiling water. The paste was boiled for 3 minutes, cooled, and 25 cc. poured into each of six 100cc. cylinders. To each of these were added the proper activating agents (5 cc. of *M* sodium chloride solution and 2.5 cc. of 0.02 *M* disodium phosphate), enough 0.01 *N* sodium hydroxide solution to neutralize the acidity of the starch, and the amino-acid to be tested, which was also properly neutralized. The mixture in each cylinder was then made up to 100 cc. with thrice distilled water and carefully stirred.

Forty-two clean, dry test-tubes were placed in a special wire frame basket in a bath of ice-water, and carefully measured portions of enzyme solution introduced into each by means of a 1cc. pipet which was accurately standardized and graduated to 0.01 cc. Portions of 5 cc. of one of the starch pastes prepared above were then introduced into each of 7 test-tubes. This was done carefully by means of a buret with a very long delivery tip reaching to the bottom of the test-tube. In this way the lodging of any

<sup>6</sup> THIS JOURNAL, 41, 1855 (1919).

<sup>9</sup> Wohlgemuth, *Biochem. Z.*, 9, 1 (1908).

<sup>10</sup> THIS JOURNAL, 37, 634 (1915).

of the starch paste on the sides of the tube was avoided. Since the tubes were kept in ice-water no measurable reaction took place.

The basket of tubes so prepared was shaken and placed in a Freas thermostat in which the temperature varied only about  $\pm 0.01^\circ$ . The tubes were thus kept at an average temperature of  $40^\circ$  for 30 minutes, when the basket was taken out and placed in ice-water to stop the action of the enzyme. After a few minutes' cooling 0.1 cc. of 0.1 *N* iodine in potassium iodide solution was added to each tube. This was done very carefully by means of a dropping bottle which delivered drops of 0.1 cc. About 20 cc. of distilled water was then poured into each tube and the contents thoroughly mixed. Each set of tubes containing the same amount of the same starch paste with various amounts of enzyme was then observed for the end-point; that is, the tube of lowest enzyme concentration which is definitely red and shows no blue or violet color due to starch.<sup>11</sup> To obtain the value of the amylolytic power of the enzyme, the weight of the 1% starch paste, (5000 mg.) is divided by the weight in mg. of enzyme present in the tube showing "the Wohlgemuth end-point" *i. e.*, the first red color not tinged by violet. Blank determinations were always made in each set; that is, starch pastes neutralized and containing the proper activators but not amino acids were used as the standard each time, since results vary slightly from day to day due to deterioration of the enzyme in solution and possibly other factors.

### Data of Typical Experiments.

Table I shows the influence of 50 mg. of arginine and 50 mg. of histidine on the amylolytic action of the amylase. It will be seen that the arginine has a distinct activating influence, while the histidine has not. These results were confirmed by other experiments.

TABLE I.  
INFLUENCE OF ARGININE AND HISTIDINE ON AMYLOCLASTIC ACTION.

<sup>11</sup> The terms used in describing the colors are those of the Milton Bradley Standard Color Chart as given by Mullikin in his "Identification of Pure Organic Compounds," John Wiley and Sons, New York, 1904.

The results of a comparison of the influence of arginine and glycine on the amylolytic action of the amylase are given in Table II. Here it is seen that both glycine and arginine activate the hydrolysis, that the activation is about the same, that a 50mg. mixture of the two gives about the same results as 50 mg. of either alone, and that a 100mg. mixture of 50 mg. of each does not seem to increase the effect.

A comparison of the influence of glycine, phenylalanine, cystine and tryptophane was made. The results are given in Table III. They show that activation is produced with each of these amino acids except tryptophane. Previous work<sup>12</sup> has shown that glycine and phenylalanine also activate the saccharogenic power of this amylase.

<sup>a</sup> The end-point tube.

It is interesting to note that the same result was obtained with different samples of histidine prepared from three different sources. (The purchased histidine dichloride was prepared from blood corpuscles by the method of Hanke and Koessler.)<sup>13</sup>

### Discussion.

In order to show whether the results obtained were due to some specific action of the amino acids themselves or to a change in the hydrogen-ion

<sup>13</sup> Hanke and Koessler, *J. Biol. Chem.*, **43**, 521 (1920).

concentration of the hydrolysis mixtures due to the addition of the amino acids, careful measurements were made of the hydrogen-ion concentrations in the starch pastes as prepared for the experiments. The results are given in Table VI and show that a practically uniform hydrogen-ion concentration of about  $10^{-7}$  was maintained in the different hydrolysis mixtures. This concentration had previously been found to give the optimum saccharogenic activity<sup>14</sup> of this amylase. In a few cases, determinations of the hydrogen-ion concentrations were made in the starch pastes both before and after digestion but no difference was found.

TABLE VI.

Arginine, (gelatin-a).....	1.2	1.1
Arginine, (gelatin-b).....	....	1.1
Glycine.....	1.1	1.1
Histidine, (casein).....	1.0	1.6 to 1.1
Histidine, (gelatin).....	...	1.1
Histidine, (purchased).....	1.1	1.6 to 1.1
Tryptophane.....	1.1	1.1
Cystine.....	...	1.6 to 1.1
Phenylalanine.....	...	1.1

The colorimetric determinations of the hydrogen-ion concentrations were made with Sorensen's phosphate buffer mixtures, as described by Clark,<sup>15</sup> as standards. The electrometric determinations were made with the Clark<sup>16</sup> rocking electrode.

Since sodium chloride and disodium phosphate were present in optimum concentration in all cases, the effects of the added amino acids cannot be due to mere change in the concentration of electrolytes in the hydrolysis mixtures.

The possible influence of a reaction between iodine and tryptophane or histidine was considered and by experiments with different measured amounts of the iodine test solution, controlled by suitable blank tests, it was shown that this was not the reason for the difference in behavior of the tryptophane and histidine compared with the other amino acids.

It is plain from the evidence presented in this and previous papers that most amino acids such as result from hydrolysis of common proteins have

<sup>14</sup> THIS JOURNAL, 41, 231-235 (1919).

<sup>15</sup> "Determination of Hydrogen Ions," by W. M. Clark, Williams and Wilkins, 1920, p. 76.

<sup>16</sup> Clark, *J. Biol. Chem.*, 23, 475-86 (1915).

a favorable influence upon the hydrolysis of starch by pancreatic amylase, while tryptophane and histidine do not.

The favorable influence shown by arginine, cystine, and all of the mono-amino acids which have been tested, may be attributed either to a direct or an indirect effect, or to both.

Let us consider first the hypothesis of direct action. Since all the amino acids here considered contain the  $\alpha$ -amino group to which it would seem that any direct activating influence must be attributed (since this is the feature which they possess in common, and the only feature to which the activating influence of glycine can be ascribed) it would follow that the negative results obtained with histidine and tryptophane must be due to some inhibitory influence exerted by their respective heterocycles.

We may, however, also conceive the favorable influence of the amino acids as being exerted not directly upon the interaction of the enzyme and the starch but rather through protecting the enzyme from deterioration in the aqueous dispersion in which it acts. In previous papers from this laboratory many observations have been recorded which seem to find their best explanation in the view that the enzyme is itself a substance of protein nature or containing protein as an essential constituent. The deterioration of the enzyme in water is markedly accelerated by rise in temperature and at the heat at which the enzyme activity is rapidly and permanently lost there is evidence of the splitting of protein substance into an albumin which coagulates and a non-coagulable product or products of hydrolysis. This and observations upon loss of enzyme activity during dialysis support the view that the deterioration of the enzyme in water is due to the hydrolysis by the water of the protein material which makes up the enzyme molecule or an essential part of it. Such hydrolysis should be retarded, and the activity of the enzyme therefore conserved, by the presence of any of the amino acids which would be formed as hydrolytic products. This would account for the fact that so many amino acids have such similar effects, since they are all products of the hydrolysis of protein material of which our purified enzyme preparations are essentially composed. The extreme sensitiveness and instability of purified pancreatic amylase in water suggests that the loss of activity probably coincides with a relatively early stage of its hydrolysis. Hence if we conceive tryptophane and histidine to be so bound in the enzyme molecule that their liberation would occur only at late stages of hydrolysis when the enzyme activity had already been lost, we should have an explanation of the difference in behavior between these and other amino acids entirely consistent with the view that the favorable influence of amino acids generally is exerted through conservation of the enzyme rather than through direct activation of it, and need not necessarily be influenced by the differences of structure which exist among the amino acids themselves.

In other words according to one hypothesis the explanation of the differences observed in our experiments with different amino acids would be sought in the structure of the amino acid radical, and according to the other, in the structure of the enzyme molecule. In our opinion both of these hypotheses may be correct and experiments designed to throw further light upon them are now in progress.

### Summary.

Two preparations of arginine obtained from gelatin, and two of histidine, one from gelatin and the other from casein, were tested for their influence upon the action of the enzyme in comparison with blank tests, with the mono-amino acids, glycine and phenylalanine, with each other, with purchased preparations of histidine and tryptophane, and with cystine prepared by another worker in this laboratory.

Tested by measuring the amylolytic action of purified pancreatic amylase upon "soluble" starch, it has been shown that arginine and cystine, like glycine and phenylalanine, influence favorably the digestion of the starch and that histidine and tryptophane do not. Consistent results were obtained with the two preparations of arginine and the three of histidine.

The tests with all these amino acids were controlled as to hydrogen-ion concentration, in most cases by both the colorimetric and the electrometric methods. It is therefore established that the influence of the amino acid upon the extent of the hydrolysis of the starch by the enzyme is not simply a matter of buffer effect or other effect upon the hydrogen-ion concentration of the digestion mixtures.

Thus it has been shown that the amino acids here studied differ among themselves in their effects upon the enzymic hydrolysis of starch, whereas the different mono-amino acids studied have shown a practically uniform behavior in this respect. Hence it appears that there are specific effects, probably though not necessarily connected with differences of structure, which may offset the favorable influence uniformly shown by the mono-amino acids studied previously. Further experiments are in progress which it is hoped will throw additional light upon the mode of action of the amino acids.

We are greatly indebted to the Carnegie Institution of Washington for grants in aid of this investigation.

NEW YORK CITY.

## NEW BOOKS.

**Physikalisch-chemische Uebungen.** Third enlarged and improved edition. By W. A. ROTH, o. Professor at the Technischen Hochschule in Braunschweig. Leopold Voss, Leipzig, 1921. viii + 278 pp. 75 fig. 23 × 15 cm. Price M 30.

This third edition, according to the preface, is photographically reproduced from the second, with 30 pages of additions necessitated by the progress of the science meanwhile. Chief among these is a 20-page section on colloid chemistry, based largely upon an introductory course formerly given by Freundlich at Braunschweig.

In the reviewer's opinion neither the changes from the first edition, nor the 10 pages of additions not concerned with colloid chemistry, suffice to bring the book up to date. At least the author should have included references to the most fundamental contributions to physico-chemical method in the last 10 years.

Waiving the 10-year limit, the reader finds only the Ostwald gas regulator for thermostats, with no mention of the possibilities of electrical heating. For the determination of the density of solids, the ancient specific-gravity bottle, with ground-glass stopper surmounted by a capillary, is still recommended. No mention is made of adiabatic calorimetry, and while there is a reference to Regnault-Pfaundler, the only method for cooling correction described is this: Correct the first half of the readings in the reaction period by the average temperature coefficient in the preliminary period, and the second half of the readings in the reaction period by the average temperature coefficient in the final period.

With the present book as his sole guide, a student could doubtless learn to perform a great variety of measurements with accuracy sufficient for most purposes. But his appreciation of modern possibilities in such work, and his critical powers, dealing with the relative importance of errors, and the underlying principles for their elimination, might be more fully developed.

G. S. FORBES.

**Physical Chemistry for Colleges.** A Course of Instruction Based upon the Fundamental Laws of Chemistry. First Edition. By E. B. MILLARD, Assistant Professor of Physical Chemistry, Massachusetts Institute of Technology. International Chemical Series, H. P. Talbot, Ph. D., Consulting Editor. McGraw-Hill Book Company, Inc., New York, 370 Seventh Avenue; London, 6 and 8 Bouverie Street, E. C. 4. 1921. vii + 411 pp. 61 fig. 14.5 × 21 cm. Price \$3.50.

In this text the author has sought "to bring before college students certain of the more important aspects of physical chemistry, together with accurate modern data which illustrate the applicability of its laws to the phenomena observed in the laboratory." He attempts to emphasize the limitations of the "orthodox laws" of physical chemistry, feeling that "a trusting belief in inadequate physical laws will only retard the scientific progress of the student, and weaken his faith in adequate laws; whereas

a wholesome appreciation that physical chemistry is an unfinished and growing science may stimulate thoughtfulness and research." In his laudable efforts to present a book which is thoroughly up to date the author has paid particular attention to the work of the last decade or so and has omitted much which might better have been included. Tastes differ, but the reviewer has a natural predilection for a certain amount of historical treatment of the subject. The names of van't Hoff, Ostwald, Nernst, Arrhenius, Kohlrausch, Hittorf, Berthelot, Thomsen, Guldberg and Waage, and many others are closely associated with the development of the subject of physical chemistry, in the reviewer's mind at least, yet in this text these investigators and theorists are all but ignored, while there are numerous references to men who have contributed comparatively little to the subject and whose scientific achievements are of comparatively little importance. The development of physical chemistry is one of the most delightful romances in history and the student who is deprived of the personal side of the story not only misses much that is due him but fails to have his enthusiasm and interest aroused. The recital of bare facts shorn of their historical and personal setting is not stimulating.

The reviewer does not believe that students profit greatly by being fed ready-made formulas. Unless they understand the development of the formula its significance is largely lost. All through this book there is a regrettable lack of development and explanation of formulas. For example, the Nernst formula for electromotive force bobs up unannounced.

No development, no explanation, not even the name of Nernst associate with it! The Gibbs-Helmholtz equation fares somewhat better, inasmuch as it is given by name, but it is not developed and the student must take it for granted and swallow it. The frequent repetition of this process must necessarily lead to much mental indigestion.

The book has many excellent qualities and will be of interest to the teacher who desires to brush up on the later developments of his subject and bring his teaching up to date. As a text it is not sufficiently comprehensive and complete for a full year's course such as is now given in most universities, but may serve where a shorter course is given and where the bare facts only are wanted. The author has brought his treatment up to date and has given many excellent examples in his problem work which supplant the time-honored ones. If a student conscientiously solves the problem work laid out he will learn a great amount of solid physical chemistry.

The statements of the fundamental laws and theories are good. A more complete discussion of fundamental units and the methods whereby they are fixed would be welcome, as the average student gets a very hazy idea of this part of the subject. The presentation of the gas laws and equations is good and the development of the kinetic equation and that

of van der Waals is satisfactory. It is believed that a discussion of the commercial liquefaction of gases might well have been included to arouse the interest of the student if for no other reason. The chapter on Solid Substances is modern and well written. Chapter V on Solutions is a mixture of "ideal solutions," "vapor pressure of solutes," "distribution between phases," "vapor pressure of ideal solutions of two liquids," "constant temperature distillation," "boiling point of solutions," "fractional distillation," "mixtures with a minimum boiling point," "distillation with steam," "freezing point of solutions," "molecular weights," and "osmotic pressure." There is no natural sequence in this arrangement nor is there any development of the relations between osmotic pressure on the one hand and boiling-point elevation, lowering of the vapor pressure and freezing-point lowering on the other. The only reference to van't Hoff is an erroneous inference that the term "osmotic pressure" was originated by him in 1886, and Pfeffer's classical work is entirely ignored. By inference (p. 141) again the student is led to believe that osmotic pressure is due to sieve action. In discussing freezing-point lowering the impression is given that thermocouples are necessary for accurate work; and in the discussion of the elevation of the boiling point the only apparatus mentioned is one first described in the literature in 1919. In Chapter VI transference numbers are discussed but no mention is made of Hittorf and his classical researches. Kohlrausch's law is not mentioned as such nor is it stated as a law.

The Chapter on Thermochemistry is excellent though one misses mention of Berthelot and Thomsen. In fact there is but one reference to work done previous to 1910.

Chapters VIII and IX deal with homogeneous and heterogeneous equilibria. In the main the treatment is good and the data well chosen with the possible exception of the example of the equilibrium between sulfur and water. While giving empirical equations for ionization, the Bates equation might well have been mentioned along with that of Kraus and Bray. The author has done well to include a discussion of indicators—a subject usually omitted.

The chapter on Kinetics of Reactions (X) contains a distinct surprise in that the important subject of catalysis is disposed of in half a page. This is indeed a serious omission inasmuch as the subject of catalysis is one of the most important in the whole realm of physical chemistry.

In Chapter XI there is given a very short discussion of the tremendously important subject of Physical Properties and Molecular Structure. This chapter should be considerably expanded and an adequate presentation made of molecular refraction and optical activity. Most of us prefer the equation of Lorentz and Lorenz for molecular refraction rather than the empirical equation of Gladstone and Dale which the author has given, and

the reviewer cannot subscribe to the inference (p. 313) that optical activity is not properly the concern of the physical chemist.

In Chapter XII we have a brief presentation of the periodic table from the modern view point, a presentation which serves well as an introduction to the two succeeding chapters. Chapter XIII gives us an excellent elementary presentation of the fundamental facts relating to Radiochemistry. This chapter and the one following (Atomic Structure) are the most interesting ones in the book and are the ones which will be of most inspirational value to the student. They are particularly acceptable because they present in an interesting way the fundamental facts and modern theories which are being much discussed at the present time. These two chapters are distinctly the high spots in the whole book.

The subject of Colloids (Chap. XV) occupies but 13 pages and suffers from the compression. The importance of Colloid Chemistry in the industries and in daily life is nowhere emphasized and there is little in the chapter to arouse the interest of the student. The final chapter is devoted to electrochemistry.

The appearance of the text is good. There are comparatively few typographical errors and most of them are obvious. The binding of the copy sent to the reviewer was not good.

In a book review the good qualities are too easily submerged. The book in question contains much that is interesting and valuable and the treatment is not a rehash of books that have gone before.

J. H. MATHEWS.

**Some Microchemical Tests for Alkaloids.** BY CHARLES H. STEPHENSON, Scientific Assistant, Bureau of Chemistry, U. S. Department of Agriculture. **Chemical Tests of the Alkaloids Used.** BY C. E. PARKER, Assistant Chemist, Bureau of Chemistry, U. S. Department of Agriculture. J. B. Lippincott Company, East Washington Square, Philadelphia, Pa., 1921. 110 pp. XXVII Plates (162 photographs). 15.5 X 23.5 cm.

The first compilation of data in a comparatively new field is always an arduous and usually a thankless task: welcomed it is true by fellow workers in the field but rarely appreciated at its full worth. Most of us wonder why the author could not have included more constants, could not have been more specific in his descriptions and included more chemistry in his discussions. Most chemists into whose hands this little book will come will doubtless ask these questions and will be inclined to lay aside the book with a feeling of disappointment. It is only after a careful examination that the reader will appreciate the time and the labor which have been expended in its preparation. It is to be regretted, however, that with so excellent a beginning the work was not completed and that the authors did not give us a comprehensive handbook on the chemical microscopy of the alkaloids, a book which is sorely needed.

The behaviors of 64 alkaloids in varying concentrations with a large number of reagents have been studied under the microscope, and the results which were obtained are briefly described by the author. These descriptions are, in the main, confined to statements of whether crystalline or amorphous precipitates were obtained; in a few instances the reader is told that the crystals formed in the reaction polarize, but in no case is the reader informed as to the character of the extinction, the crystal system or other optical properties of the crystals which are formed, data invaluable in the identification of compounds under the microscope. It is the absence of these data that detracts much from the value of the book for the chemist and the toxicologist. The data presented appear to have been compiled solely from the view point of, and for the average microscopist who is interested only in whether a given reagent will or will not cause the separation of crystals when added to a drop of an alkaloidal solution. Nowhere does the author introduce any statements concerning the chemistry of the alkaloids or of the reactions obtained, nor has he taken advantage of our knowledge of the constitution of many of the common alkaloids and employed organic compounds as reagents and thus obtained identity tests based upon chemical constitution. It is largely due to this lack of chemistry in our literature relating to chemical microscopic tests that the development of chemical microscopy has been retarded and that chemists do not take more kindly to this type of qualitative analysis. The method adopted by the author for performing the tests, "Place one drop of the alkaloidal solution on a microscope slide and add, by means of a glass rod, one small drop of the reagent," is not always conducive to the best results nor can we thus obtain the most uniform and most characteristic crystals.

The photomicrographs illustrating the crystal forms which were obtained in the different tests are excellent and exceptionally well executed. They represent a high degree of skill and have been selected with care and good judgment. An index to the plates adds greatly to their usefulness for ready reference.

Had the arrangement adopted in the first 83 pages (large type headings) been retained in the pages devoted to, "Chemical Examinations" (pp. 84-105) or if an index to the text had been added, it would have materially improved the book and saved the reader time and annoyance. As it is, the discussion of one alkaloid follows immediately after another without change of type or spacing, so that the chemical tests upon a given alkaloid are not quickly found.

As a guide for the beginner in the microscopic detection of the alkaloids, this book, aside from its excellent photographs, has little to recommend it; but considered as a compilation of facts relative to the behavior of alkaloidal solutions toward a number of inorganic reagents it is a distinctly valuable contribution to our heretofore meagre knowledge of these tests and should

find a place upon the shelves of all analysts who have occasion to make analyses of alkaloid-containing materials.

E. M. CHAMOT.

**The Physiology of Protein Metabolism.** Second Edition. By E. P. CATHCART, M. D., D. Sc., F. R. S., Gardiner Professor of Chemical Physiology, University of Glasgow. Longmans, Green and Co., Fourth Ave. and 30th Street, New York; 39 Paternoster Row, London; Bombay, Calcutta and Madras; 1921, viii + 178 pp. 15.5 X 24.5 cm. Price \$4.25 net.

The second edition of this very important and well balanced volume covers essentially the same field as that of the first edition. Since the appearance of the first edition in 1912 many epoch making investigations have been recorded and in the present edition a successful attempt has been made to bring the book up to date. To this end many sections have been entirely rewritten and a new chapter has been added summarizing the influence of the non-nitrogenous foodstuffs on the metabolism of protein. For the student of nutrition the book is invaluable.

FRANK P. UNDERHILL.

**Die Schwimmaufbereitung der Erze.** By PAUL VAGELER. Theodor Steinkopff, Dresden and Leipzig, 1921. pp. v + 98. 23 X 16 cm. Price 4 shillings, 4 pence.

The author was apparently captured in German Southwest Africa during the war and he learned about ore flotation from the English. On p. 6 he points out how much better the Germans study such matters than the Anglo-Saxons. The reviewer does not feel called upon to praise the scientific studies of Minerals Separation; but the author has not carried the matter very far. He states that adsorption is a factor—which everybody knows—and there he stops. There is no adequate discussion of froth formation; there is nothing serious in regard to the difference, if any, between insoluble and soluble flotation agents; there is nothing to show where the ore particles are in the froth though that was a matter of some apparent importance in one of the trials; there is nothing to show why saponin acts as it does; and the Tennessee experiment of adding copper sulfate to a zinc ore is mentioned as an unexplained mystery. There is no question but that several Anglo-Saxons could have written a much better book than this. It is in the general style of Wolfgang Ostwald—high-sounding phrases and nothing that one can take hold of as definite.

There is also a good deal of padding in the book. The diagrammatic pictures of the neutral helium atom and of the oxygen molecule have very little to do with the problems of ore flotation. On the other hand, it is true, though rather obvious, to say, p. 85, that the advantages of the flotation method are relatively less the greater the cost of grinding. The book is utterly inadequate and it is difficult to see how it can be helpful to anybody.

**THE FREE ENERGY OF DILUTION AND THE ACTIVITIES OF THE  
IONS OF POTASSIUM BROMIDE IN AQUEOUS SOLUTIONS.**

By J. N. PEARCE AND HARRY B. HART.

Received August 2, 1921.

In a study of "The Activity of the Ions and the Degree of Dissociation of Strong Electrolytes," Lewis<sup>1</sup> has calculated the degrees of dissociation of a large number of uni-univalent salts. These calculations are based on the assumption that in solutions of different electrolytes containing a common ion this ion has the same mobility at any one concentration. From the results obtained he finds that in a 0.1 *M* solution the chlorides, bromides and iodides of hydrogen and the alkali metals are all dissociated to practically the same extent. In order to interpret the changes in the transport numbers of the ions which accompany change in concentration he advances two hypotheses: "(1) that all the ions increase in mobility with increasing ion concentration, the increase being relatively greater, the greater the original mobility; (2) that all the ions decrease in mobility with increasing ion concentration, the decrease being greater the smaller the original mobility." He concludes that the first of these hypotheses is the more probable and advances two probable causes for an increase in ionic mobility with increasing concentration. These are: (1) a gradual

<sup>1</sup> Lewis, *THIS JOURNAL*, 34, 1631 (1921).

dehydration, which although undoubtedly present does not play a dominant part, and (2) an added increase in the ordinary conductivity of the electrolyte due to a conduction of the Grotthus type. The additional conduction due to this effect would account for the assumed increase in mobility.

Making the same assumption regarding the independent mobility of the ions, MacInnes<sup>2</sup> also finds that the alkali chlorides are dissociated to the same extent in 0.01 *M* concentration. This observation led him to advance the hypothesis that for the same molal concentration the activity of the chloride ion is a constant and is independent of the cation associated with it. Further on the basis of the striking similarity of the weight and the mobility of the potassium and chloride ions he assumes that these ions have the same activity in a solution of the salt. Using the available electromotive-force data, MacInnes has calculated the activities of the ions in various solutions of potassium chloride and hydrochloric acid.

Noyes and MacInnes<sup>3</sup> have calculated for a wide range of concentrations the mean activity coefficients of the ions of potassium chloride, hydrogen chloride, lithium chloride and potassium hydroxide.

During recent years there has developed the hypothesis of complete dissociation of strong uni-univalent electrolytes. The possibility of complete dissociation was first suggested by Noyes,<sup>4</sup> and the hypothesis has been further substantiated by the work of Milner,<sup>5</sup> Ghosh,<sup>6</sup> Bjerrum,<sup>7</sup> Brönsted,<sup>8</sup> Hill<sup>9</sup> and others. While this hypothesis demands that the electrolyte be completely dissociated at all concentrations, the number of ions actually free at any one time is limited by various factors involved in the solution process. For any given concentration of the electrolyte a definite fraction of the ions are loosely united, as a result of electrostatic attraction, to such an extent that they are not capable of independent activity and mobility. These "bound" ions, therefore, possess the properties which we have usually attributed to undissociated molecules. Hence, there should exist in a solution of an electrolyte an equilibrium between the electrically bound ions and the simple ions which in the "free" state are capable of independent activity and mobility.

In a recent paper Harned<sup>10</sup> has found that the hypothesis of complete

<sup>9</sup> Hill, *ibid.*, **43**, 254 (1921).

<sup>10</sup> Harned, *ibid.*, **42**, 1808 (1920).

dissociation is a good working hypothesis. He has also confirmed the MacInnes hypothesis of the independent activity of the ions. Furthermore, he has computed the individual activity coefficients of the hydrogen, sodium, potassium, lithium and chloride ions in concentrations 0.1 to 3.0 *M*.

Up to this time practically all of the work dealing with ionic activities has been confined to a study of the ions in aqueous solutions of the alkali chlorides and hydrochloric acid. We have thought it worth while, therefore, to extend these investigations by a study of the activity of the ions in solutions of potassium bromide, thus making possible a direct comparison of the activities of the chloride and bromide ions.

#### Materials and Apparatus.

Potassium bromide of a high grade was further purified by crystallizing twice from distilled water and twice from "conductivity" water. The mercury used in preparing the amalgam was first repeatedly sprayed through a long column of dil. nitric acid and then distilled in a current of air under reduced pressure.

In preparing the silver bromide electrodes small pieces of platinum foil, in the form of electrodes, were first electrolytically plated with a firm white deposit of metallic silver. They were then arranged as anodes in a solution of potassium bromide and coated with silver bromide, using a current density of 2 m. a. for 15 minutes. The electrodes thus prepared are of a steel-gray color and are easily reproducible to within 0.05 m.v. The potassium amalgam was made by distilling mercury over into metallic potassium, *in vacuo*, after the method of Lewis and Kraus.<sup>11</sup> It was then filtered through a fine capillary into a suitable storage flask and preserved under an atmosphere of pure dry hydrogen. The amalgam used throughout contained 0.2122% of metallic potassium.

Owing to the fact that the oxidation of the potassium by dissolved oxygen materially changes the potential of the amalgam electrodes, every possible precaution was taken to exclude air from the solutions. To this end the exact amount of salt for a given volume concentration was transferred to a volumetric flask fitted with a stopper and a filling device permitting easy transfer of the solution to and from the flask. Water was then added and the solution boiled. To insure the removal of every trace of air a stream of pure hydrogen was bubbled through the boiling solution. The solution was then cooled to the desired temperature and diluted to the desired volume by adding conductivity water which had been similarly treated. The solution was then weighed on a sensitive balance and its molal concentration calculated. At no time thereafter nor during the potential measurements which followed did the solution come into contact with the air.

A large oil-bath electrically controlled gave temperatures constant to 0.02° for any desired temperature. All potential measurements were made on a Wolff potentiometer, using as a standard of reference a recently certified Weston cadmium cell, (No. 3554: 1.01956 volt).

#### Precision and Duplication.

Three silver bromide electrodes having a maximum variation of not more than 0.05 m.v. were placed in each half-cell and allowed to stand until equilibrium was established between the electrodes and the potassium bromide solution. A period of 4 hours was found to be sufficient for this purpose. Only those electrodes in any half-cell were

<sup>11</sup> Lewis and Kraus, *THIS JOURNAL*, 32, 1459 (1910).

used in the measurements which checked, over all, to 0.03 m.v. In case no such agreement was attained the cell was dismantled and set up anew. When at any temperature the electromotive forces had become constant final readings were taken and the temperature changed. In this way the electromotive forces of the various cells were obtained at 25°, 30° and 35°.

### Experimental.

In the present work the following types of cells have been studied: (A)  $\text{Ag} | \text{AgBr, KBr } (c) | \text{K.Hg}_x$ ; (B)  $\text{Ag} | \text{AgBr, KBr } (c_1) | \text{K.Hg}_x - \text{Kg}_x \cdot \text{K} | \text{KBr } (c_2), \text{AgBr} | \text{Ag}$ ; (C)  $\text{Hg}_x \cdot \text{K} | \text{KBr } (c_1), \text{AgBr} | \text{Ag} - \text{Ag} | \text{AgBr, KBr } (c_2) | \text{K.Hg}_x$ ; (D)  $\text{Ag} | \text{AgBr, KBr } (c_1) | \text{KBr } (c_2), \text{AgBr} | \text{Ag}$ ; (E)  $\text{Hg}_x \cdot \text{K} | \text{KBr } (c_1) | \text{KBr } (c_2) | \text{K.Hg}_x$ .

**Measurements of the Cells.**—The amalgam electrodes employed are similar to those first used by Lewis and Kraus,<sup>11</sup> and later by Allmand and Polack.<sup>12</sup> The mean value of the electromotive forces for at least two successive set-ups of this type of cell for any one concentration are given in Table I. The values of the electromotive forces for these different set-ups do not differ by more than 0.10 m.v., except for the 2.8032 *M* concentration where a difference of 0.20 m.v. was observed. The values of the electromotive forces of a cell containing exactly 0.10 *M* concentration of potassium bromide at the three temperatures was calculated by means of an empirical quadratic equation expressing the electromotive force as a function of the concentration. These values are inserted at the bottom of Table I. The electromotive forces for the 0.25258 *M*, 0.10048 *M* and 0.050148 *M* were used in these calculations.

**The Free-energy Decrease and the Heat-content Decrease Attending the Cell Reaction.**—The free-energy decrease ( $-\Delta F$ ), expressed in joules, attending the reaction in any cell is obtained by multiplying the electro-

<sup>12</sup> Allmand and Polack, *J. Chem. Soc.*, 115, 1020 (1919).

motive force of the cell by 96494. If now we express the free energy decrease as a function of the temperature by means of the equation,

$$(-\Delta F)_t = (-\Delta F)_{25} [1 + \alpha(t-25) + \beta(t-25)^2],$$

we can calculate the temperature coefficients of free energy decrease. These values together with the free energy decrease are collected in Table II. The values for the decrease in heat content  $(-\Delta H)$  attending the cell reaction given in the same table have been calculated with the aid of the thermodynamically derived relation,

$$(-\Delta H)_{25} = (-\Delta F)_{25} [1 - \alpha \times 298.09].$$

TABLE II.

0.10000	210945	209807	208688	-1088.0	+1.6	279355

Although of the same order of magnitude the values of  $(-\Delta H)$  are irregular. These irregularities are, however, within the limits of experimental error. The effects due to a simultaneous error of 0.10 m.v. at 25° and 35°, respectively, have been calculated. While a deviation of this magnitude causes a variation of only 0.005% in the value of  $(-\Delta F)$  it produces a change in the temperature coefficient ( $\alpha$ ) sufficient to produce an error of 2% in the value of the heat-content decrease.

**The Free-energy Decrease Accompanying the Transfer of One Mole of Potassium Bromide from Various Concentrations (c) to 0.10 M.—**

TABLE III.

0.001001	-21471	-21797	-22193

From the free-energy decrease attending the cell reaction at the various concentrations we can now obtain, by subtraction, the free-energy decrease attending the transfer of one mole of potassium bromide from a solution of any given concentration to one exactly 0.1 *M*. These values expressed in joules are given in the accompanying table.

**Measurement of Concentration Cells without Ion Transference.—**

(B).  $\text{Ag} \mid \text{AgBr}, \text{KBr} (c_1) \mid \text{K.Hg}_x - \text{Hg}_x.\text{K} \mid \text{KBr} (c_2), \text{AgBr} \mid \text{Ag}.$

(C).  $\text{K.Hg}_x \mid \text{KBr} (c_1), \text{AgBr} \mid \text{Ag} - \text{Ag} \mid \text{AgBr}, \text{KBr} (c_2) \mid \text{Hg}_x.\text{K}.$

The particular construction of the cell used rendered easy and convenient the determination of the electromotive forces of cells of both types, (B) and (C). In every set-up a complete set of readings was made on each type of cell and the potentials compared. Since the electromotive force of either of these cells depends, at any given temperature, solely upon the logarithms of the ratios of the activity products of the two ions at the molal concentrations ( $c_1$ ) and ( $c_2$ ), the electromotive forces of (B) and (C) should be identical. The mean potentials of each of the two types do not in any case differ by more than 0.03 m.v. For this reason we have entered in Table IV only those potential readings derived from Cell B. These data are easily reproducible and are accurate to 0.03 m.v.

TABLE IV.  
ELECTROMOTIVE FORCES OF CONCENTRATION CELLS WITHOUT ION TRANSFERENCE.

**The Free Energy of Dilution and the Decrease in Heat Content Attending the Transfer of One Mole of Potassium Bromide from Concentration  $c_1$  to  $c_2$ .—**The decrease in free energy, expressed in joules, attending the transfer of one mole of potassium bromide from concentration  $c_1$  to concentration  $c_2$  has been obtained by multiplying the electromotive force of the cell by 96494. These results together with the temperature coefficients of free energy decrease are given in Table V. The values for the decrease in heat content attending the same transfer have also been calculated and are included in the same table. The value of  $\alpha$ , if potassium bromide behaved as a perfect solute, would be 0.003353. The corresponding decrease in heat content is zero. While these theoretical values are approached it will be observed that even at the highest dilutions employed potassium bromide does not behave as a perfect solute.

**Measurements of the Cells with Ion Transference.**— $\text{Ag} | \text{AgBr}, \text{KBr} (c_1) | \text{KBr} (c_2), \text{AgBr} | \text{Ag}$ . The cells with ion-transference employed in this work were made by joining two of the half-cells containing silver bromide electrodes by a flowing-junction device similar to that described and used by Lamb and Larson.<sup>13</sup> This arrangement gave results that were easily reproducible to 0.03 m.v. Table VI contains a summary of these results.

TABLE VI.

**The Transference Numbers of the Potassium Ion.**—Thermodynamically the electromotive force of a concentration cell with ion transference is given by the relation:

$$E_t = \frac{N_K RT}{F} \ln \frac{C_1^2 \cdot \alpha_1^+ \cdot \alpha_1^-}{C_2^2 \cdot \alpha_2^+ \cdot \alpha_2^-},$$

where  $N_K$  represents the transference number of the potassium ion,  $(\alpha_1^+, \alpha_1^-)$  and  $(\alpha_2^+, \alpha_2^-)$  are the activity coefficients of the ions at concentrations  $c_1$  and  $c_2$ , respectively.

The corresponding expression for the electromotive force of a cell without ion-transference is

$$E = \frac{RT}{F} \ln \frac{C_1^2 \cdot \alpha_1^+ \cdot \alpha_1^-}{C_2^2 \cdot \alpha_2^+ \cdot \alpha_2^-}.$$

The ratio,  $\frac{E_t}{E} = N_K$ , gives us directly the transference number of the potassium ion. These values are recorded in Table VII. From these results it is to be observed that dilution is accompanied by a slight but

<sup>13</sup> Lamb and Larson, THIS JOURNAL, 42, 229 (1920).

gradual increase in the transference number. The effect of temperature change is practically negligible between 25° and 35°.

TABLE VII.

**The Activity Coefficients of the Ions.**—From the observed electromotive forces, Table IV, it is possible to calculate, by adding algebraically, the electromotive force of a cell containing any two of the concentrations employed in this work. In this manner the electromotive forces given in the following table have been computed. If now we make the assumption that at 0.001001  $M$  (0.001  $N$ ), the activity of the ions is equal to their concentration, as determined from conductance measurements, the product of the activity coefficients,  $\alpha_K + \alpha_{Br^-}$ , at any other concentration can be calculated directly. These values, thus calculated, are given in Table VIII.

TABLE VIII.  
THE ELECTROMOTIVE FORCES OF CONCENTRATION CELLS INVOLVING EACH CONCENTRATION ( $c$ ) WITH 0.0010017  $M$  AND THE ACTIVITY COEFFICIENT PRODUCTS AT THE CONCENTRATION ( $c$ ).

0.010021	0.11346	0.7914
0.005009	0.07956	0.8493
0.001001	0.00000	0.9565

In their study of the activity of largely ionized substances, Noyes and MacInnes<sup>3</sup> have computed from electromotive-force data the mean activity coefficients of the ions of potassium hydroxide, potassium chloride, lithium chloride and hydrochloric acid. Since for any given concentration the potassium and chloride ions are assumed to possess equal activities, the mean activity coefficients for this salt may be considered as the activity coefficient of either of its ions. If now we assume that at any given concentration the activity of the potassium ion is a constant and independent of the anion associated with it, we are in a position to calculate the activity of the bromide ion. In order to make these calculations the values of

$\alpha_{K^+ \cdot Br^-}$ , (Table VIII), were plotted on a large scale against the logarithms of the concentrations. From the curve thus obtained the values of  $\alpha_{K^+ \cdot Br^-}$  corresponding to round concentrations were then read. These activity coefficient products were then divided by the value of  $\alpha_{K^+}$  for potassium chloride at the same concentration, taken from the data of Noyes and MacInnes.<sup>3</sup> The quotients obtained are obviously the activity coefficients of the bromide ion.

The results of these computations are summarized in Table IX. The second column contains the values of  $\alpha_{K^+} = \alpha_{Cl^-}$  taken from the data of Noyes and MacInnes. Col. 3 contains the values of  $\alpha_{K^+ \cdot Br^-}$  read from the curve, while Col. 4 contains the values of  $\alpha_{Br^-}$  calculated in the manner described in the preceding paragraph. The values given in the fifth column are the values of  $\alpha_{Br^-}$  calculated in a similar manner from the data of Lewis and Storch.<sup>14</sup>

TABLE IX.

0.050	0.790	0.6260	0.792	.....
0.030	0.823	0.6785	0.824	0.822
0.010	0.890	0.7930	0.891	0.886
0.005	0.923	0.8520	0.922	.....
0.003	0.943	0.8885	0.942	.....
0.001	0.979	0.9565	0.978	.....

A glance at the above table shows conclusively that at equal molal concentrations, at least up to 0.5 *M*, the activity coefficients of the chloride and bromide ions are identical. Furthermore, the close agreement between the values of the activity coefficients of the bromide ion computed from the data for potassium bromide and those calculated from the data for hydrogen bromide is further evidence of the independent activity of the individual ions.

Since the completion of the experimental part of this paper there has appeared an article by Lewis and Randall<sup>15</sup> on the activity coefficients of strong electrolytes. Using the data of Bates and Kirschmann<sup>16</sup> on the partial vapor pressures of the hydrogen halides, Lewis and Randall have arrived at the same conclusion regarding the activity coefficients of the

<sup>14</sup> Lewis and Storch, *THIS JOURNAL*, **39**, 1544 (1917).

<sup>15</sup> Lewis and Randall, *ibid.*, **43**, 1112 (1921).

<sup>16</sup> Bates and Kirschmann, *ibid.*, **41**, 1991 (1919).

chloride, bromide and iodide ions. These results indicate further that the differences observed in the activity of the various uni-univalent halides, when at the same concentration, are due primarily to differences in the activity of the cations.

### Summary.

1. Measurements of the electromotive forces of the cells

have been made.

2. The free-energy decrease and the decrease in heat content attending the reaction in these cells have been calculated.

3. The free energy decrease attending the transfer of one mole of potassium bromide from various concentrations ( $c$ ) to 0.10  $M$  have been computed.

4. The electromotive forces of concentration cells with ion transference and without ion transference have been measured. From these values the transference numbers of the potassium ion have been calculated.

5. The free-energy decrease and the heat-content decrease accompanying the transfer of one mole of potassium bromide from concentration  $c_1$  to concentration  $c_2$  have been computed.

6. The activity coefficients of the bromide ion have been calculated and a comparison made of the activity coefficients of the chloride and bromide ions. For all concentrations up to 0.5  $M$  the activity coefficients of these two ions are practically equal.

## THE SOLUBILITY OF SILVER CHLORIDE IN DILUTE CHLORIDE SOLUTIONS AND THE EXISTENCE OF COMPLEX ARGENTICHLORIDE IONS. II.<sup>1</sup>

BY GEORGE SHANNON FORBES AND HARRIET ISABELLE COLE.

Received August 12, 1921.

In a previous paper by one of us,<sup>2</sup> where earlier work on this subject was discussed, the solubility of silver chloride in concentrated chloride solutions was proved proportional to integral powers of chloride concentration. From these results was inferred the existence of the complex ion  $\text{AgCl}_4^=$  in the higher concentrations, and of  $\text{AgCl}_3^=$  in the range from 1.5  $N$  down to 0.5  $N$ . Below that point, however, the constant indicating the latter ion increased, which suggested that the ion  $\text{AgCl}_2^-$  might predominate at the lowest concentrations.

<sup>1</sup> This work was performed in 1915, at Simmons College.

<sup>2</sup> See Forbes, *THIS JOURNAL*, 33, 1937 (1911).

The present paper records an effort to investigate solutions less than normal in chloride, which necessitated the measurement of solubility to 0.05 mg. per liter.

Sodium and potassium chlorides were precipitated by hydrogen chloride, washed, dried and ignited. Other salts were recrystallized from redistilled water, and made up into concentrated stock solutions. Silver nitrate solution, 0.001 *N*, was similarly prepared. Portions of the stock solutions were weighed from weight burets and analyzed with the customary precautions, including careful standardization of weights. The greatest variation between duplicate analyses was 6 parts in 10,000.

An 800cc. deep-form beaker was weighed clean and dry with a glass stirrer. The desired amount of solid salt or of stock solution was weighed out, and the volume made up to about 500 cc. with redistilled water carefully protected from dust. The beaker was brought to 25.0° in a thermostat electrically regulated to 0.05°. It was then placed in a blackened wooden box with a comparison beaker containing a similar solution. On the other side of the glass partition was placed a 300-watt tungsten lamp. Black rings at the tops and bottoms of the beakers excluded annoying reflections. If both beakers were equally free from opalescence, a quantity of 0.001 *N* silver nitrate known from preliminary experiments to be just insufficient to cause opalescence was run into the first beaker with vigorous stirring. After an hour at 25°, which had been proved enough to develop opalescence if it was to appear at all, the beaker was carefully wiped, and once more examined in the modified nephelometer, to prove the continued absence of precipitate. Two drops of the silver solution, or 5 in the most concentrated solutions, were added, with vigorous stirring, and the beaker returned to the thermostat for another hour, after which it was again examined and so on. It appeared improbable that supersaturation would greatly exceed the last addition of silver nitrate, about  $6 \times 10^{-8}$  mole in 500 cc. in this case.<sup>3</sup> When opalescence appeared, the total weight of the solution was at once determined, also its density by pycnometer. The concentrations in the solution at the end-point could then be calculated without uncertainty due to evaporation or change in volume on mixing. The results appear in Tables II to IV.

The total silver present at the end-point may be classified as follows: (a) silver ion, (b) dissolved molecules of silver chloride, supersaturated or unsaturated, (c) precipitated silver chloride, and colloid in dispersion not too high to be seen under the given light conditions, (d) silver chloride in complex ions and molecules, and possibly adsorption complexes of colloidal silver chloride too highly dispersed to be visible under the given light conditions.

Assuming the solubility product to be  $2 \times 10^{-10}$ , the  $(\text{Ag}^+) = 2 \times 10^{-10} / (\text{Cl}^-)$ . As this correction is in all the cases less than  $3 \times 10^{-8}$  mole in 500 cc. it will be neglected for the moment.

<sup>3</sup> Compare Ref. 2, p. 1939.

The working hypothesis was now tried that the silver chloride in the conditions (b) and (c), under the constant experimental conditions, made up a constant total which may be expressed as  $b$ . Let us also postulate

TABLE I.

EVALUATION OF  $b$  FOR SODIUM CHLORIDE.Let  $b = \text{AgCl as Dissolved Molecules} + \text{Colloidal} + \text{Precipitated}$ .

$$k_1 = \frac{\text{total silver}_1 - b}{\text{total chloride}_1} = \frac{\text{total silver}_2 - b}{\text{total chloride}_2}$$

Total chloride.	Total silver.	$b$ .	Total chloride.	Total silver.	$b$ .
{ 3.86	0.00072	0.00058	{ 17.58	0.00131	0.00077
{ 9.24	0.00091		{ 36.54	0.00189	
{ 17.58	0.00131	0.00047	{ 88.44	0.00361	0.00068

Average = 0.00063

that (complex silver) = (total silver -  $b$ ). If it be further assumed that the complex radical in dilute solutions is  $\text{AgCl}_2$ , then  $(\text{AgCl}_2) = k_1$  (total chloride). Combining, (total silver -  $b$ ) =  $k_1$  (total chloride). The two unknowns,  $b$  and  $k_1$  may now be evaluated by solving at any two concentrations, but pairs of concentrations below 0.1  $N$ , where  $b$  is not small in comparison with total silver, and where the complex is sharply defined, promise the best results. Table I shows 4 values of  $b$  thus determined for sodium chloride with an average of 0.00063, while 5 similar pairs with hydrochloric acid yielded 0.00061. The closeness of the agreement, though in the main accidental, does yet in some measure justify the assumption made.

The total silver present in complex form, and the values of  $k_1$  are given in Tables II to IV. The value of  $k_1$  varies without definite trend up to 0.1  $N$ , after which it tends to increase rapidly, while  $k_2$ , calculated on the assumption that the complex radical is  $\text{AgCl}_3$ , approaches constancy as shown in the previous paper. Table IV, in which total chloride is constant, shows substantially the same effects of the positive radical

<sup>4</sup> Richards and Wells, *Carnegie Inst. Pub.*, 28, 29 (1905).

one of the results with nitric acid, doubtless erroneously, indicates a decrease in solubility. A trace of alum is without effect, which suggests that colloid formation is relatively unimportant under the given conditions.

The "activity" conception of G. N. Lewis and others was duly considered before presenting these results. In the previous paper it was shown that complex formation in hydrochloric acid at higher concentrations, at least, is always less than in sodium chloride. The activity of hydrochloric acid, however, always exceeds that of sodium chloride, and at 5 *N* it is 5 times as great.<sup>5</sup> The quantitative application of the activity principle must therefore be postponed. In the present work, also, it was found that *b* and *k* were more constant if total chloride concentrations were used without correction for either ionization or activity coefficient. Possibly chloride molecules, as well as chloride ions, operate to form complexes. At first sight, this seems inconsistent with the observation in the previous paper that the feebly ionized zinc chloride shows but little tendency to form the argentichloride complex. But here self-complex formation, as  $\text{ZnCl}_2 + 2\text{Cl}^- = \text{ZnCl}_4^{2-}$  is no doubt considerable.

In very dilute solutions, the total concentration of silver in "true solution" exclusive of the constant *b* should equal the sum of silver ion and of argentichloride ion per liter, *i. e.*,  $2 + 10^{-10}/(\text{MCl}) + k_1(\text{MCl})$ . By "true solution" is meant one optically clear under the light conditions described above, and one doubtless filterable without loss through a filter paper or Gooch crucible. Differentiating total silver with respect to chloride concentration, we find that the condition under which the derivative becomes zero is  $(\text{MCl})^2 = 2 \times 10^{-10}/k_1$ . Using  $0.34 \times 10^{-4}$  as the average value of *k*<sub>1</sub> the minimum total concentration of silver in true solution should be found at 0.0025 *N*, instead of at 0.01 *N*, as predicted in the previous paper under the assumption that the complex radical  $\text{AgCl}_2$  persisted in the most dilute solutions. At 0.0025 *N*,  $2 \times 10^{-10}/(\text{MCl}) = 8 \times 10^{-8}$  and  $k(\text{MCl}) = 8 \times 10^{-8}$ , by a curious coincidence. The total silver concentration exclusive of the constant *b* is therefore  $1.6 \times 10^{-8}$  mole, or 0.000025 gram per liter. According to the present work, no chloride solution can contain less than this amount of silver chloride per liter in true solution, if just a bare trace of freshly precipitated silver chloride is present.

At first sight, the results of this paper might seem in preposterous disagreement with those of Richards and Wells, who found a solubility of 0.000003 g. per liter<sup>6</sup> in a solution containing perhaps an excess of 0.1 equivalent of chloride per liter. It should be emphasized, however, that these determinations were made in filtrates from large precipitates of silver chloride, whose enormous surfaces may have occluded or adsorbed the com-

<sup>5</sup> Lewis and Randall, *THIS JOURNAL*, 43, 1117, 1123 (1921).

<sup>6</sup> Richards and Wells, *Ref. 4*, p. 30.

plex most obstinately. Indeed, these authors suggest that even glass might adsorb sufficient silver chloride to account for losses observed on standing.<sup>7</sup> Another possibility is that chloride solutions, in the absence of much adsorbing solid, peptize silver chloride in a strictly reproducible fashion.<sup>8</sup> If so, the degree of dispersion must be very high. The possibility that more than one form of silver chloride with different solubilities may exist, is not excluded. The behavior of silver chloride is so variable under changing conditions that even the above noted difference is not disconcerting, though it invites further investigation.

### Summary.

To various chloride solutions less than 0.1 *N* in concentration, 0.001 *N* silver nitrate solution was added to incipient precipitation, at 25°. The total silver was invariably given by the sum:  $2 \times 10^{-10}/(\text{MCl}) + 3.4 \times 10^{-5}(\text{MCl}) + b$ , where  $2 \times 10^{-10}$  is the solubility product,  $3.4 \times 10^{-5}$  a constant possibly connected with a complex of the type  $\text{AgCl}_2$ , and *b* apparently is the constant sum of silver chloride in precipitate, in dispersion, and in dissolved molecules. The great difference between this observed total and the minute silver content of filtrates from large precipitates of silver chloride is discussed.

Silver chloride should be most insoluble, at 25°, in 0.0025 *N* chloride solutions.

## THE USE OF THE WATER INTERFEROMETER AS A PRESSURE GAGE.<sup>1</sup>

BY L. VAN DOREN, H. K. PARKER AND P. LOTZ.

Received August 18, 1921.

Nitrogen-filled glass manometers have been used in this laboratory for many years for the measurement of osmotic pressure, although there are certain objections to their use for this purpose; and since it was desired to measure pressures greater than they could withstand (about 100 atmospheres) it was necessary to devise a suitable manometer for this purpose. Frazer and Myrick<sup>2</sup> by use of a resistance pressure gage were able to measure osmotic pressure of concentrated sucrose solutions with approximately the same sensitivity at all pressures, but here also,

<sup>1</sup> Richard and Wells, Ref. 4, p. 29.

<sup>2</sup> See Homochemical Compounds, V. Veimarn, *Kolloid Z.*, **28**, 97 (1921).

<sup>1</sup> This work was assisted by grants from the Carnegie Institution of Washington, and was carried out at the suggestion of J. C. W. Frazer.

<sup>2</sup> Frazer and Myrick, *THIS JOURNAL*, **38**, 1907 (1916).

due to hysteresis effects in the resistance coils and consequent shifting of the zero, the method was not entirely satisfactory. The construction of the apparatus described below which is devoid of these objections, is believed to be satisfactory for this purpose and may also have other similar applications.

The instrument is a modification of the Zeiss water interferometer. Instead of using this instrument in a method for the analysis of solutions it is here used to measure pressure differences.

Figs. 1a and b show respectively the construction of the Zeiss water interferometer and its modifications for use as a pressure gage. In the Zeiss instrument white light from a slit is made parallel by a collimating lens, *L*, and passes through the rectangular openings *R*<sub>1</sub>, *R*<sub>2</sub> as two beams, which, reflected from the mirror, *M*, pass back and unite at

Fig. 1.

*O* forming a system of interference fringes and are viewed by a suitable eye-piece. The similar chambers *C*<sub>1</sub>, *C*<sub>2</sub>, are placed, one in the path of each beam. When the optical paths are different, as is the case when one of the chambers contains the pure solvent and the other a solution, the interference fringes are displaced to a position at the left or right of *O*. The displacement is compensated by means of the inclined plate *P*<sub>1</sub>, *P*<sub>2</sub> being fixed. The measurement of the amount of adjustment of *P*<sub>1</sub> necessary to bring back the central bright fringe to the zero position is used as a means of analyzing a solution for a single variable component or several mutually dependent components. The water interferometer adapts itself readily to use as a pressure gage by simply altering the cells *C*<sub>1</sub>, *C*<sub>2</sub> in such a way that the water contained in one of them is kept under atmospheric pressure while that in the other is subjected to the pressure to be determined. For this purpose the cells *C*<sub>1</sub>, *C*<sub>2</sub> are replaced by pressure chambers. These are parallel holes about 6.25 mm. in diameter bored through a solid bronze cylinder and fitted at each end with heavy plate-glass windows *A*, Fig. 1b. Just beneath the pressure chambers the bronze cylinder is provided with a longitudinal slot for beams of light which form the stationary bands of reference.

When pressure is applied to the water in one of the chambers its refractivity is increased and the interference fringes are displayed. The adjustable plate mentioned above enables one to compensate for this

displacement, and it is readily seen that such an instrument after having been calibrated may be used for the measurement of any pressure within the range of adjustment covered by the movable plate.

The chief difficulty to be overcome was to obtain a tight joint between the plate glass windows and the pressure chamber. Fig. 1b shows the construction of one end of the bronze block. A washer C was cut from 3 mm. soft sheet rubber with beveled sides so as to fit the countersunk end of the pressure chamber. This washer is cut slightly oversize, thus giving good contact and insuring a tight joint. A dilute solution of rubber is spread around the washer and hole of the non-pressure chamber, which is not countersunk and requires no washer as no pressure is developed in this chamber.

After assembling and allowing the solvent to evaporate, the chamber is dried thoroughly and a slow stream of gaseous sulfur chloride is blown into the chambers for 10 minutes. This operation vulcanizes the rubber to the required hardness. The glass plate is held in place by a brass plate G, of the same thickness and cut to fit the glass plate snugly. The latter is held tightly against the end of the chamber by a similar brass plate H on which a washer B, made of asbestos and rubber, is placed to take up any unevenness in the glass. Finally, pressure is brought to bear on H by a screw collar E. Some difficulty was experienced in obtaining a suitable washer material to place between the glass and the outside brass plate. When soft thin rubber washers were used the pressure caused them to flow from the small brass section between the pressure chamber and the opening below, thus leaving the glass plate unevenly supported and causing leaks. When harder materials, as leather, were used the windows were frequently broken when pressure was applied. The packing which was successful is used in steam packing and for gaskets and is sold under the trade name of "Durabla Packing." It answered our purpose in having sufficient resilience to take up any unevenness, possessing no tendency to flow, and not requiring any take-up after pressure is applied.

### Increased Range of the Interferometer.

On calibration, the pressure limit of the apparatus, was found to be approximately 60 atmospheres. It was therefore found necessary to devise some means by which the range of the instrument could be increased. This was accomplished by inserting a thin glass plate in the path of the beam passing through the non-pressure chamber, the glass plate being of such thickness that, when inserted, it would compensate for approximately 60 atmospheres. With this plate inserted we thus had a range of from 60 to 120 atmospheres, approximately. The final adjustment for reading is accomplished by the usual method of tilting the glass plate of the interferometer. Thus, by making up several slides with plates of increasing thickness we were able to extend the range of the apparatus to any pressure required.

The glass plates were attached firmly to brass frames by Canada balsam, the plates being machined to fit into slides attached to the water bath of the interferometer.

We found that thin microscope-cover plates were quite regular in thickness and proved easily adaptable to the problem at hand. The plates used varied in thickness from 0.1016 to 0.3556 mm.

The method of mounting these thin glass plates was such that they

could be replaced in exactly the same position and thus any error that would arise from any slight irregularity in the plate was avoided.

### Calibration of Apparatus.

The apparatus was calibrated against an absolute pressure gage in the Geophysical Laboratory.<sup>3</sup> The calibration was made at both 20° and 30°. In the data for Plate 6 it was found necessary to read a different band as our zero point at 30° than was read at 20°, hence the apparent discrepancy in the calibration for this plate. The personal equation in reading the interferometer as used for pressure measurements is considerable but care was taken to calibrate in the same manner as when using the instrument for the measurement of pressure. This instrument has been used satisfactorily for the direct measurement of osmotic pressure as described in the following article.

## THE OSMOTIC PRESSURES OF CONCENTRATED SOLUTIONS OF SUCROSE AS DETERMINED BY THE WATER INTERFEROMETER.

BY PAUL LOTZ AND J. C. W. FRAZER.

Received August 18, 1921.

Many difficulties are encountered in the direct measurement of the osmotic pressures of solutions among which are those involved in measuring the pressure. The limit of pressure that the glass manometer will stand as found by Frazer and Myrick is about 100 atmospheres. Among the uncertainties involved in the use of gas manometers are the deviation of gases from Boyle's law, and the fact that gas may be occluded between the mercury and the glass, both of which may become appreciable when measuring high pressures. The percentage error involved in reading the levels of the mercury menisci also increases with the compression of the gas and the change of form of the meniscus is not to be disregarded. So the higher the pressure the less accurate the gas manometer becomes.

Frazer and Myrick<sup>2</sup> by the use of the resistance pressure gage were able to obtain a constant sensitivity at all pressures, but owing to certain difficulties such as hysteresis in the resistance coils it was thought wiser to seek a method for measuring high pressures that would be less objectionable.

Berkeley and Hartley<sup>3</sup> determined the osmotic pressure of several solutions up to pressures of 133 atmospheres by applying mechanical pressure and determining the equilibrium pressure by noting the point at which the solvent just ceases to pass through the semipermeable membrane.

In an article by Woods<sup>4</sup> the objection is raised that the osmotic pressure of solutions as measured is not the true osmotic pressure, but of that layer of solutions in immediate contact with the semipermeable membrane

<sup>4</sup> Röntgen and Zehnder, *Wied. Ann.*, 44, 34 (1891).

<sup>1</sup> This work has been assisted by grants from the Carnegie Institution of Washington.

which is more concentrated than the solution proper, due to adsorption. This criticism applies more particularly to dilute solutions and has been partly answered by the work of Minter and Frazer.<sup>5</sup> They used a stirring device which could be operated during the time the measurements were being made.

The same osmotic pressure was also obtained by allowing the pressure to rise by the diffusion of solvent through the membrane as was obtained by submitting the solution to a hydrostatic pressure greater than the equilibrium pressure, which latter pressure is reached by the removal of solvent from the solution through the membrane.

### Apparatus.

The water interferometer as adapted to the measurement of pressure<sup>6</sup> was used in this work for measuring the osmotic pressures developed. The cells used were made by the method of Frazer and Myrick,<sup>2</sup> the membrane of copper ferrocyanide being deposited on the outside. The container of bronze was also the same as used in the above work.

Fig. 1.

When attempting the measurements at  $55.7^\circ$  it was found necessary to modify the washer used between the cell shoulder and the cell container, due to the flowing of the rubber at this high temperature and pressure. This was prevented by inserting a bronze washer between the cell shoulder and washer as shown in insert Fig. 1.

### Temperature Control.

In the  $30^\circ$  experiments the entire apparatus was placed in a  $30^\circ$  air-

<sup>5</sup> Minter and Frazer, unpublished dissertation. Johns Hopkins University, 1917.

<sup>6</sup> Van Doren, Parker and Lotz, *THIS JOURNAL*, 43, 2497 (1921).

bath which varied but  $0.05^{\circ}$ . In the  $57.7^{\circ}$  experiments the cell and container were placed in a double-walled copper bath in which the constant temperature was maintained by boiling acetone in the outer compartment. The inner compartment containing the cell surrounded by water was cylindrical in shape, 10 cm. in diameter and 25 cm. high. With a bath of these small dimensions stirring was found unnecessary. Temperature varied from day to day about  $0.1^{\circ}$  with change in the atmospheric pressure but the time required to complete an experiment was very short, the maximum period required to obtain equilibrium being  $2\frac{3}{4}$  hours, in which interval no changes in temperature could be detected.

This form of apparatus fulfilled all expectations, proving convenient, strong, and of quick action, as the results in Table I show. Equilibrium was obtained in from 12 minutes for the lower concentrations to  $3\frac{3}{4}$  hours for the measurements at high concentrations. In the  $2 M$  measurements at  $55.7^{\circ}$  the final reading obtained after adjusting the apparatus was maintained throughout the experiment showing that equilibrium had been obtained even before the time recorded in the table.

In the  $30^{\circ}$  work all solutions used were at  $30^{\circ}$ , in the  $55.7^{\circ}$  work the solutions were cooled somewhat below  $55.7^{\circ}$  in order to lessen the effect of dilution of the solution being measured.

### Experimental.

**Preparation and Analysis of Solutions.**—Aqueous solutions of cane sugar were studied over the complete range of solubility. The sucrose used was carefully purified "rock candy." To facilitate ready comparison with previous work done in this laboratory, the solutions were all made up on the weight molar basis using atomic weights on the  $O = 16$  scale. The sugar in each instance was dissolved in distilled water made  $0.01 N$  with potassium ferrocyanide. The solvent against which the osmotic pressures were measured was  $0.01 N$  copper sulfate.

The extent to which the solutions were diluted during measurement was ascertained by the saccharimeter in the following manner. From the optical rotation, the concentration was determined by reference to a curve made by plotting the values of the ratios of the concentrations of the original solutions to their optical rotations against *their* optical rotations, *i. e.*, letting  $C$  represent the concentration, and  $r$  the optical rotation, the values of  $C/r$  were plotted against the values of  $r$ . By multiplying the optical rotation of a given solution by the corresponding value of  $C/r$  as determined from the curve, the concentration of the solution in grams of sugar for 1000 g. of water was obtained.

In the work on dilute solutions carried on in this laboratory, corrections for changes in concentration are made by changing the observed pressure the same percentage that the optical rotation of the solution changes during the measurement. This involves two errors, for it assumes that the change in optical rotation is linearly proportional to the change in concentration and that the osmotic pressure is a linear function of the concentration. The magnitude of the error may be negligible in the case of dilute solutions but in the case of concentrated ones the error would be

considerable. Hence in this work the final concentrations are determined from the curve described above and the observed osmotic pressures are recorded as the pressures of solutions of these concentrations.

The contents of the solvent compartment were examined after each experiment to determine to what extent the sugar had leaked through the membrane. The amount of sugar in the "solvent" could not be detected by the saccharimeter in any of our measurements except in Expt. 11. The cell used here was an old one that had not been used for several years and was set up without seasoning. All of the other cells used had been well seasoned at high pressures and gave very satisfactory results.

\* Unseasoned Cell.

### Results.

Table I summarizes the experiments. Some were lost and not recorded, due to the washers breaking; and hence no analysis could be made of these solutions. In Expt. 26 the upper washer was broken and the ex-

periment was incomplete. No importance is attached to the result obtained in Expt. 11, as we found that the results obtained with unseasoned membranes as shown by solute leakage are invariably low and the true equilibrium pressure is not reached.

Frazer and Myrick report sugar leakage after reaching concentrations of 5 *M* and greater. We should therefore expect to find their results at these higher concentrations somewhat low. On plotting a curve with their results, *i. e.*, osmotic pressure against concentrations—a decided drop in the curve is noticed after passing 5 *M* concentrations. In comparing their results for corresponding concentrations with the results of Expts. 12 and 13 our predictions are found to be correct, since we obtained 200.2 and 206.1 as compared with 192.0 and 200.0, respectively, found by Frazer and Myrick.

The results obtained in this work for 6 *M* sucrose when substituted in the above curve of Frazer and Myrick give a continuous and regular curve at 30°.

In Fig. 2 the data in Table I are shown graphically. Here the concentration expressed in g. of sucrose for 1000 g. of water is plotted against the osmotic pressure in atmospheres. It will be noticed that the curve for 55.7° cuts the extrapolated 30° curve at a concentration of 2000 g. of sucrose to 1000 g. of water. Above this concentration the osmotic pressure of solutions at 55.7° is less than that of like concentration at 30°.

### Discussion.

Woods<sup>4</sup> calculated the value for osmotic pressure from the vapor-pressure measurements obtained by him for concentrated solutions of sucrose by using the Porter equation which connects the osmotic pressure and the vapor pressure of the solution and solvent. Data for 3 solutions of concentrations 92.0, 156.6 and 224.3 g. of sucrose to 100 g. of water respectively were obtained at temperatures from 60° to 90°.

He noticed that in the two more concentrated solutions the osmotic pressure as calculated showed a distinct tendency to diminish with rise in temperature.<sup>7</sup> The results obtained in this work indicate that, while

<sup>7</sup> Results obtained in this laboratory on sugar solutions up to *M* concentrations showed the same tendency, *i. e.*, to increase less than the theoretical value.

Fig. 2.

the calculated values obtained by Woods may be high, the relative values are not far from correct.

From a perfect solution the osmotic pressure would increase with rise in temperature according to the gas laws. Here, however, the increase is much less than the theoretical increase. This is quite evident even with the less concentrated solutions, while on approaching concentrations of 6 *M* the osmotic pressure at 55.7° becomes actually less than the values obtained at 30°.

It has been firmly established that these sugar solutions warm when diluted adiabatically. If we were then to accept the suggestion made by Woods that negative heats of dilution imply an association of solute molecules, the amount of which becomes greater at the higher temperatures, then the dynamical explanation would be that the increased association more than balanced the increase of kinetic pressure due to the rise in temperature.

Callender<sup>8</sup> has elaborated the vapor-pressure theory of Poynting and according to his view, when the heat of dilution is small, as it is, at any rate, with moderately strong solutions,

$$\Pi_r = \frac{N-an}{N-an+n} \pi_0$$

where *a* is a hydration factor representing the number of solvent molecules associated with each molecule of solute;  $\Pi_r$ , the vapor pressure of the solution;  $\Pi_0$ , the vapor pressure of the solvent; *N*, the mol fraction of the solvent; *n*, the mol fraction of the solute. If, on the other hand, Callender's hydration factor *a* changes, owing to the formation of simpler hydrates at the higher temperature, then one might consider the increase in effective dilution due to the liberation of the water previously attached to the sugar molecules to be responsible for the decrease in the osmotic pressure.

Woods also integrates the equations of Porter as applied to the results of Berkeley and Hartley

$$P = \frac{nRT}{V-nb}$$

and obtains 
$$\frac{dP}{dT} = \frac{P}{T} \left( 1 + \frac{P}{R} \frac{db}{dT} \right)$$

which makes *P* independent of the temperature when  $db/dT = -R/P$ . Then, for a solution whose osmotic pressure is 180 atmospheres, a loss of 1 molecule of water for each 40° rise of temperature would suffice in order that the osmotic pressure remain unchanged with rise in tem-

<sup>8</sup> Callender, *Proc. Roy. Soc.*, 80A, 466 (1908).

perature. A greater rate of dehydration than this would involve a decrease of the osmotic pressure with rise of temperature.

Woods, however, believes that this stage is not reached in the cases he studied and attributes the apparent decrease in his calculated values to a too rapid variation of the ratio of  $\Pi_0/\Pi_\infty$  with temperature. This conclusion seems unjustified. The loss by dehydration must reach such a magnitude at concentrations of 6 *M* and over that the increase in solvent due thereto more than balances the increase of kinetic pressure due to rise in temperatures.

### Summary.

1. In this article the authors describe a modification of the method used by Frazer and Myrick for measuring the osmotic pressure. The principle feature of the new apparatus is the use of the water interferometer in determining the magnitude of the pressures developed.

2. The apparatus affords a decided improvement over the method of Frazer and Myrick, being somewhat quicker in action and more dependable. Pressures up to 273 atmospheres have been measured, while the pressure chambers have been calibrated up to 330 atmospheres.

3. Measurements over the entire range of solubility are given for 30° and 55.7°.

4. Attention is called to the results of Woods as calculated for vapor-pressure measurements, and it is shown that his results, showing a decrease in osmotic pressure with rise in temperature with concentrated solutions, are relatively correct although his actual values for the osmotic pressure seem to be high as compared with these direct measurements.

## THE EQUILIBRIUM IN MIXTURES OF BINARY ELECTROLYTES.

By CHARLES A. KRAUS.

Received August 24, 1921.

### 1. Introduction.

The determination of the equilibrium in a mixture of electrolytes is a problem of considerable practical importance since many of the reactions with which we have to deal are carried out in mixtures of this kind. If the law of mass action is applicable to the resulting equilibrium, then the problem is in general soluble, provided intermediate ions are not formed. In all likelihood this condition is fulfilled in mixtures of binary electrolytes, but, as Harkins<sup>1</sup> has pointed out, when higher types of salts are present, intermediate ions are probably formed. The following discussion will therefore be limited to mixtures of binary electrolytes.

<sup>1</sup> Harkins, *THIS JOURNAL*, 33, 1807 (1911); 38, 2679 (1916).

In mixtures of strong electrolytes the problem of determining the concentration of the various molecular species present is complicated owing to the fact that the law of mass action in its simple form does not hold. We therefore have no means for calculating the equilibrium in these mixtures save such as are purely empirical in character. In the past the determination of the equilibrium in mixtures of strong electrolytes has been founded upon the isohydric principle of Arrhenius.<sup>2</sup> This principle has a theoretical foundation so long as the electrolytes involved in the reaction obey the simple law of mass action, but in the case of strong electrolytes this relation is purely an empirical one.

Presumably, in a mixture of strong electrolytes where the mass-action law does not hold, the various molecular species present will obey laws similar to those obeyed by the same molecular species in solutions containing a single electrolyte. The form of the function assumed as governing the equilibrium in a mixture should therefore agree with that of the salts alone in aqueous solution. Assuming that the ionization is measured by the ratio  $\Lambda/\Lambda_0$ , the form of the function in the case of pure electrolytes is known, although the equation remains uncertain. Nevertheless, various empirical functions which have been proposed account for the experimental values in the case of binary electrolytes with considerable precision over large ranges of concentration. As we shall see presently, the isohydric principle, when formulated mathematically, reduced to the proper form in the case of a solution of a single binary electrolyte. It is interesting to determine what other functions may be assumed to hold in mixtures which will reduce to the same form in the case of a solution of a single electrolyte.

## 2. The Isohydric Principle.

The isohydric principle is based upon the observation that if two electrolytes, having an ion in common, are mixed, then the ionization of the two electrolytes in the mixture will be the same as that in the original solutions before mixing, if the concentrations of the common ion in these solutions before mixing are equal. This result is a consequence of the law of mass action. Let  $M_1^+$  and  $X^-$  be the concentration of the ions in two solutions, where  $X^-$  is that of the common ion. If the concentrations of the common ion in the two solutions are the same before mixing, then obviously we have

$$M_1^+ = M_2^+ = X^-. \quad (1)$$

The total salt concentrations of the two solutions  $C_1$  and  $C_2$  will in general be different. Let  $V_1$  liters of the first solution be mixed with  $V_2$  liters of the second solution. If the conditions of Equation 1 are fulfilled, and if no displacement takes place in the equilibrium on mixing, then we should

<sup>2</sup> Arrhenius, *Z. physik. Chem.*, 5, 1 (1890); compare also 2, 284 (1888).

have for the concentration of the ions  $M_1^+$  in mixture the value  $\frac{M_1 + V_1}{V_1 + V_2}$  for that of the common ion  $\frac{M_1 + V_1 + M_2 + V_2}{V_1 + V_2}$ , and for that of the unionized fraction of the first salt  $M_1X_1 \left( \frac{V_1}{V_1 + V_2} \right)$ .

If the law of mass action holds, we have,

$$\frac{M_1 + V_1}{V_1 + V_2} \times \frac{M_1 + V_1 + M_2 + V_2}{V_1 + V_2} \times \frac{V_1}{M_1X_1(V_1 + V_2)} = K_1. \quad (2)$$

Equation 1 being fulfilled, it is obvious that we have

$$\frac{M_1 + V_1 + M_2 + V_2}{V_1 + V_2} = M_1^+;$$

and Equation 2 reduces to

$$\frac{M_1^+ + X_1^-}{M_1X_1} = K_1.$$

In other words, if the conditions expressed in Equation 1 is fulfilled by the original solutions before mixing, then no displacement takes place in the equilibrium when these solutions are mixed in any proportions what ever.

In the case of mixtures of weak acids and bases where the law of mass action holds, this consequence of the law of mass action has been substantiated. Since the conductance of solutions of acids is due chiefly to the hydrogen ion, it follows that the conductance of a mixture of two acids will be the same as that of the acids before mixing, provided the original solutions have the same specific conductance. In this it is assumed that the conductance of the anion in the two acids is the same. If this condition is not fulfilled, it is obvious that the conductance of the mixture will vary as a linear function of the composition of the two solutions which have the same concentration of the hydrogen ion.

It has been found, however, that even in the case of solutions which do not conform to the law of mass action, that is, solutions of strong electrolytes, a similar condition holds. If, for example, solutions of ammonium chloride and potassium chloride are mixed, the specific conductance of the mixture will be (approximately) independent of the proportions of the original solutions taken, provided that these solutions have the same specific conductance. Apparently, then, the isohydric principle holds even though the law of mass action is not obeyed. This principle has, therefore, been employed for the purpose of calculating the equilibrium in mixtures of strong electrolytes.

The law of equilibrium for a given electrolyte in a mixture must obviously reduce in the limit to that of solutions of electrolytes in the pure solvent. It has been shown that for strong electrolytes the following equation<sup>3</sup> holds approximately,

$$P_i/C_u = D(\Sigma C_i)^m + K, \quad (3)$$

where  $P_i$  is the value of the ion product,  $C_u$  is the concentration of the unionized fraction,  $\Sigma C_i$  is the concentration of all the positive or negative ions in the solution, and  $D$ ,  $m$  and  $K$  are constants. It is evident that this equation conforms to the isohydric principle. Indeed, any equation of the form

$$P_i/C_u = F(\Sigma C_i) \quad (4)$$

conforms to the isohydric principle. Here  $F(\Sigma C_i)$  is any explicit function of the total ion concentration of the mixture. For, on mixing two solutions whose ion concentrations are  $C_i'$  and  $C_i''$ , the equilibrium will be unaffected by the relative volumes of the solutions mixed, provided that  $C_i' = C_i''$ . Equation 4, therefore, is the analytical expression for the equilibrium in the mixture according to the isohydric principle. In the limit, as the second component in the mixture disappears, the equation reduces to that of the first salt alone. Obviously the same equation may be applied to mixtures of electrolytes without a common ion.

### 3. An Alternative Principle Which May Be Assumed to Govern the Equilibrium in Mixtures of Electrolytes.

Equation 4 is not the only function which fulfils the condition that it reduces to the form of Equation 3 in the case of a single electrolyte. We may assume for the mixture the function,

$$P_i/C_u = F(P_i), \quad (5)$$

where  $P_i$  is the ion product. In the limit the concentrations of the positive and negative ions become equal for a solution of a single electrolyte and consequently the equation reduces to the form of Equation 3. Equations 4 and 5, therefore, both fulfil the condition that they reduce to the proper form in the special case that only a single electrolyte is present in solution. In order to determine which of these equations is more nearly applicable to a mixture, it is obviously necessary to measure some independent property of these mixtures; such as the conductance, for example. Assuming that the conductance of the ions in the mixture is the same as that of the same ions dissolved alone in water, it is possible to calculate the specific conductance of the mixture if the form of the conduction functions for the pure electrolytes is known and if a function is assumed to hold for the mixture. If the assumed function is correct, then the calculated specific conductance of the mixture should correspond

<sup>3</sup> Kraus and Bray, *THIS JOURNAL*, 35, 1315 (1913); Kraus, *ibid.*, 42, 1 (1920).

to the measured specific conductance within the limits of experimental error. If the calculated values do not so correspond, it indicates that the function so assumed for the mixture is not applicable.

#### 4. Test of Functions 4 and 5 in the Case of Mixtures of Sodium Chloride and Hydrochloric Acid.

Bray and Hunt<sup>4</sup> have measured the specific conductance of mixtures of sodium chloride and hydrochloric acid in water at 25°. They have likewise calculated the specific conductance of the mixtures assuming the isohydric principle; that is, assuming Equation 4. The results are given in the following table, where the concentrations of sodium chloride and

hydrochloric acid are given in the second and third columns respectively, the measured specific conductance in the fourth column, and in the fifth column the specific conductance calculated according to Equation 4. Finally, in the sixth column are given the percentage deviations between the measured and the calculated values. In the same table, in Column

<sup>4</sup> Bray and Hunt, *THIS JOURNAL*, 33, 781 (1911).

7, are given the values of the specific conductance calculated according to Equation 5, and in the last column the percentage deviations between the calculated and the observed values.

Comparing the measured values with those calculated on the basis of Equation 4, it is seen that the deviations from the isohydric principle are consistently larger than any conceivable experimental error. With mixtures containing 0.1 *N* solutions of sodium chloride, the mean error is -1.15%; for 0.02 *N* solutions of sodium chloride, the mean deviation is -0.75%; and for 0.005 *N* solutions of sodium chloride, the mean deviation is -0.57%. The values of the specific conductance calculated according to Equation 4 are throughout greater than the observed values. At the lower concentrations the agreement between the observed and calculated values is measurably better than at the higher concentrations, but, in all cases, the discrepancies are far in excess of any conceivable experimental error. It is true that at the high concentrations the results may be affected owing to the influence of viscosity, but this certainly cannot be the case at the lowest concentrations.

The values of the specific conductance as calculated according to Equation 5 exhibit, throughout, a better agreement with the measured values than those calculated according to the isohydric principle, particularly at the lower concentrations. In mixtures containing 0.10 *N* sodium chloride the mean deviation of +0.85% is unquestionably far in excess of the experimental error. However, in mixtures containing 0.02 *N* sodium chloride the mean deviation has fallen to +0.33%, which is not greatly in excess of the experimental error. Finally, in mixtures containing 0.005 *N* sodium chloride, the mean deviation has fallen to 0.05%, which is well within the limits of experimental error. At the higher concentrations, the values of the specific conductance, calculated according to Equation 5, are throughout somewhat less than the measured values. At the lowest concentration, namely, 0.005 *N* sodium chloride, the differences are both positive and negative.

In calculating the specific conductance of the mixtures according to Equation 5, the values assumed for  $\lambda_0$  were 127.0 and 424.0 for sodium chloride and hydrochloric acid, respectively. Bray and Hunt state that the calculated value of the specific conductance is not materially affected by the value assumed for  $\lambda_0$ . So, also, in calculating the specific conductance according to Equation 5, the values assumed for  $\lambda_0$  have only a secondary effect upon the resulting value of the specific conductance. For example, assuming for hydrochloric acid and sodium chloride the  $\lambda_0$  values 422 and 125.4 respectively, the calculated specific conductance according to Equation 5 is 3.097 for point 11. The divergence resulting from change in the values of  $\Delta_0$  naturally varies somewhat with the concentration.

The results given above cannot be said to establish the correctness of the principle expressed by Equation 5, in the case of mixtures of strong electrolytes. Nevertheless, it appears that this principle yields results which are more nearly in agreement with experiment than are those based on the isohydric principle, which is commonly employed for this purpose. The isohydric principle leads to erroneous results even at very low concentrations, whereas the alternative principle leads to results in agreement with the experimental values at low concentrations. It is, of course, possible that in the case of mixtures other than those of sodium chloride and hydrochloric acid a similar agreement may not be found. However, electrolytes of a given type in aqueous solutions exhibit such similarity in their behavior that it is probable that similar results will be found in other mixtures.

The isohydric principle has been extensively employed for calculating the concentrations of the various molecular constituents present in mixtures. Since this principle does not hold, it is obvious that the concentrations of the various constituents so found are subject to considerable error. These errors may not greatly affect the concentrations found for certain of the molecular species, but, in the case of others, the errors may be very great. In those cases where the effect of electrolytes upon the solubility of other electrolytes has been studied, the conclusion has been reached that the concentration of the un-ionized fraction of the salt present as solid phase is greatly diminished by the addition of a second electrolyte. Since the isohydric principle, which underlies these calculations, is not correct, it seems not improbable that the great change found in the concentration of the un-ionized fraction is a consequence of applying to the mixture a principle which in fact does not hold. If we make the assumption that the un-ionized fraction of a salt, which is present as solid phase, remains constant on the addition of a second electrolyte, then it follows, from Equation 5, that the ion product likewise remains constant. This result is, on the whole, in agreement with observations on the solubility of binary electrolytes in the presence of other electrolytes with a common ion. In another paper the solubility relations in the case of binary electrolytes will be discussed more in detail.

### Summary.

1. It is shown that the isohydric principle, when applied to mixtures of electrolytes, leads to a functional relation of the form  $(C_i)^2/C_{\pm} = F(2C_i)$ .
2. As the concentration of the second electrolyte diminishes, the function  $P_i/C_{\pm} = F(P_i)$  reduces, in the limit, to the same form as the function resulting from the isohydric principle.
3. The values of the specific conductance of mixtures of sodium chlo-

ride and hydrochloric acid as calculated according to this principle are shown to furnish a better agreement with the measured values than are those based on the isohydric principle.

## GHOSH'S THEORY OF ELECTROLYTIC SOLUTIONS.

By CHARLES A. KRAUS.

Received September, 10, 1921.

### 1. Introduction.

The so-called "anomaly" of solutions of strong electrolytes has been one of the outstanding problems of chemistry almost since the inception of the Ionic Theory. Attempts which have been made to account for the behavior of these solutions from a theoretical standpoint have not met with marked success. In most instances such theories have been designed to account for only a limited number of the characteristic properties of electrolytic solutions and they have rarely been extended to include non-aqueous solutions.

In a series of articles<sup>1</sup> Ghosh has recently advanced a theory of electrolytic solutions which is very comprehensive in its scope, and which is founded upon somewhat novel assumptions with regard to the nature of electrolytes and their solutions. He has developed relations to account for nearly all important properties of electrolytic solutions in different solvents and has compared the consequences of his theory with existing experimental data. Therefrom he draws the conclusion that his theory is fully substantiated.

If Ghosh's theory is correct, it will be necessary to alter greatly the present day treatment of the properties of electrolytic solutions. Since, ultimately, the soundness of any theory must be judged by the degree of correspondence between the experimental data and the consequences resulting from the theory, a consideration of the postulates and assumptions upon which the theory of Ghosh is founded may be deferred until this theory has been examined from an experimental point of view.<sup>2</sup> The question to be answered is: To what degree of precision is Ghosh's theory able to account for the experimental data? If the theory is correct in its essential details, as Ghosh believes it to be, then it should render substantial account of the experimental results. Systematic deviations, between the consequences of the theory and the experimental facts should

<sup>1</sup> Ghosh, *J. Chem. Soc.*, 113, 449, 627, 777, 790 (1918).

<sup>2</sup> Partington (*Trans. Faraday Soc.*, 15, 111 (1919-20)) has criticized certain features of Ghosh's theory and Ghosh has replied to the same (*ibid.*, 15, 154 (1919-20)). This discussion, however, has left many points in an uncertain state.

appear only under conditions not included within the scope of the theory as postulated.

## 2. Method of Testing the Equation.

In examining a theory of this kind, whose purpose is to account for the relation between a dependent and a number of independent variables, it is practically necessary to resort to graphical methods, for in no other way is it possible to comprehend at a glance the degree of correspondence between theory and experiment, as one or another of the independent variables is subjected to change. The only graph which has a decided value for this purpose is one which leads to a linear relation between the independent and the dependent variables under consideration. Where the equations involving the variables in question are complex, other variables must be chosen such that a linear relation exists between them, which, in some cases, renders the problem difficult, since various undetermined constants may be involved. In the case of the Ghosh Equation, however, a comparison by graphical method is both simple and conclusive, since a linear relation exists between the experimentally determined variables themselves. The conductance is expressed as a function of the concentration by means of the equation

$$\log \Lambda = \log \Lambda_0 - \frac{\beta C^{1/3}}{DT} \quad (1)$$

where

$$\beta = \frac{NE^2 (2N)^{1/3}}{2.3026 mR}$$

Here  $N$  is Avogadro's number,  $6.16 \times 10^{23}$ ,  $E$  is the electrostatic unit of charge,  $4.7 \times 10^{-10}$  e.s.u.,  $R$  is the value of the gas constant in absolute units, and  $m$  is a factor depending upon the number of ions  $n$  produced from a single neutral molecule and upon the number of charges associated with a single ion, as well as the manner of distribution of these ions in the solvent medium. It is evident that, for a given solvent at a given temperature, the logarithm of the equivalent conductance is a linear function of the cube root of the concentration. Any systematic deviations between the experimental and the theoretical values will at once be apparent if the experimental values of  $\log \Lambda$  and of  $C^{1/3}$  are represented graphically. This method of treatment, moreover, obviates any assumption with respect to the values for the constants  $\Lambda_0$  and  $\beta$ , since, if the theoretical equation holds, the experimental values will follow a linear relation from which the values of the constants may be uniquely determined.

## 3. Aqueous Solutions of Potassium Chloride.

In Fig. 1, values of  $\log \Lambda$  are plotted as ordinates and those of  $C^{1/3}$  as abscissas for solutions of potassium chloride in water at  $18^\circ$ ; the data

being due to Kohlrausch and Maltby,<sup>3</sup> and to Washburn and Weiland.<sup>4</sup> According to Ghosh,  $\beta$  should have the value  $3.620 \times 10^3$  for binary electrolytes in water,  $C$  being expressed in mols per liter. In the figure the straight line drawn, passing through the point  $C^{1/2} = 0.2154$ , corresponds to Ghosh's equation. Ghosh assumes a value of 122.5 for the conductance of potassium chloride at 0.01  $N$ , in determining the value of  $\Lambda_0$ . The value due to Kohlrausch, however, is 122.37. For the purpose of comparison, therefore, the straight line corresponding to Ghosh's equation has been drawn through this point at an angle corresponding to the value of  $\beta$  assumed by Ghosh, namely,  $\beta = 3.620 \times 10^3$ .

In the following table are given the calculated and observed values of  $\Lambda$  for solutions of potassium chloride in water at 18°, together with the differences between the observed and the calculated values.

TABLE I.

COMPARISON OF OBSERVED AND CALCULATED VALUES OF  $\Lambda$  FOR POTASSIUM CHLORIDE IN WATER AT 18°.

	$\Lambda_0 = 132.06.$		$\beta = 3.620 \times 10^3.$		$T = 291.$	$D = 81.$	
$V$ .....	$5 \times 10^4$	$2 \times 10^4$	$10^4$	$5 \times 10^3$	$2 \times 10^3$	$10^3$	$5 \times 10^2$
$\Lambda_{\text{calc}}$ .....	130.80	130.35	129.90	129.35	128.40	127.47	126.30
$\Lambda_{\text{obs}}$ .....	129.51	129.32	129.00	128.70	128.04	127.27	126.24
$\Lambda_{\text{obs.}} - \Lambda_{\text{calc.}}$ ...	-1.39	-1.03	-0.90	-0.45	-0.36	-0.20	-0.06
$V$ .....	$2 \times 10^2$	$10^2$	50	20	10	5	2
$\Lambda_{\text{calc}}$ .....	124.31	122.37	119.97	116.9	112.1	107.4	99.7
$\Lambda_{\text{obs}}$ .....	126.24	122.37	119.90	115.6	111.8	107.5	101.3
$\Lambda_{\text{obs.}} - \Lambda_{\text{calc.}}$ ...	+0.03	$\pm 0.00$	-0.07	-0.3	-0.3	-0.1	+1.6

The conductance values, as determined by Kohlrausch and by Washburn and Weiland have a relative precision greater than 0.1%. In all likelihood the mean error does not exceed 0.05%. At the higher concentrations the conductance is measurably affected by the viscosity change of the solution due to the added salt. Since Ghosh subsequently employs conductance values corrected for viscosity,<sup>5</sup> these corrected values have been employed in the comparison whose results are given above. It is evident that the observed values of  $\Lambda$  diverge from the theoretical curve at concentrations above approximately  $2 \times 10^{-2} N$  and below  $10^{-3} N$ . These deviations greatly exceed the probable experimental error. The experimental curve is concave toward the axis of concentrations in dilute solutions and convex toward this axis in concentrated solutions with an inflection point at an intermediate concentration. The curve resulting from Ghosh's equation is very nearly tangent to the experimental curve in the neighborhood of the inflection point. Whether

<sup>3</sup> Kohlrausch and Maltby, *Wiss. Abh. phys.-tech. Reichsanstalt*, 3, 210 (1900). Noyes and Falk, *THIS JOURNAL*, 34, 454 (1912).

<sup>5</sup> Ghosh, *Trans. Faraday Soc.*, 15, 154 (1919-20).

this coincidence possesses a real significance or is merely an accidental result may be determined by an examination of non-aqueous solutions. It is well known that at lower concentrations the ionization curves for aqueous solutions of different binary electrolytes are practically identical and consequently what is true of solutions of potassium chloride will be true of other solutions of binary salts in water.

Ghosh's equation reduces to the form  $\Lambda_0 - \Lambda = AC^{1/2}$ , at very low concentrations. This equation is one of the empirical functions employed by Kohlrausch for representing the equivalent conductance of electrolytes as a function of their concentration. Ghosh looks upon this as lending support to his theory. It may be noted, however, that, as Kohlrausch himself pointed out, the cube root function yields a curve concave toward the axis of concentrations at low concentrations.<sup>6</sup> In determining the value of  $\Lambda_0$ , therefore, Kohlrausch employed a corre-

Fig. 1.—Curves for KCl in  $H_2O$  and  $NEt_4I$  in epichlorohydrin.

sponding extrapolation function in which the concentration appears with the exponent  $1/2$  in place of  $1/3$ . This result of Kohlrausch is in entire accord with the results as plotted in Fig. 1, where the experimental curve is markedly concave toward the axis of concentrations at low concen-

<sup>6</sup> Kohlrausch and Maltby, Ref. 3., p. 218.

trations. It is clear that the equation of Ghosh cannot be looked upon as exact. However, in view of the fact that the theoretical curve coincides in slope with the experimental curve in the neighborhood of the inflection point, it will be necessary to examine solutions in other solvents than water in order to determine whether or not Ghosh's theory contains in it certain elements of truth.

#### 4. Application to Freezing-Point Data.

Before proceeding to a consideration of the conductance curve in non-aqueous solutions, we may examine the results of Ghosh's theory as applied to the freezing points of aqueous solutions of electrolytes. For the value of the van't Hoff factor  $i$ , Ghosh obtains the equation<sup>7</sup>

$$i = n \left( 1 - \frac{1}{3} \log \frac{1}{\gamma} \right), \quad (2)$$

where  $n$  is the number of ions into which the electrolyte dissociates, and  $\gamma$  is the ionization, as calculated from Ghosh's Equation 1. According to the usual ionic theory, the value of  $i$  is given by the equation,  $i = 1 + (n-1)\gamma$ , where, as before,  $n$  is the number of ions into which the electrolyte dissociates and  $\gamma$  is the degree of ionization as calculated from conductance measurements, the value of  $\Lambda_0$  being extrapolated by means of empirical functions.

It is a well-known fact that for dilute solutions of many electrolytes, such as potassium chloride, for example, the value of  $i$ , as determined from freezing-point measurements, agrees within the limit of experimental error with the value as determined from conductance measurements on the basis of the usual ionic theory. It follows, therefore, that the values of  $i$ , as calculated from Equation 2, cannot be in agreement with the experimentally determined values of  $i$ . In the following tables are given the values of  $i$  as calculated according to the equations of Ghosh, assuming the constants given in Table I, together with the experimentally determined values of Adams<sup>8</sup> and the values calculated from conductance measurements in the usual way.

TABLE II.

COMPARISON OF THE EXPERIMENTALLY DETERMINED VALUES OF  $i$  WITH THOSE CALCULATED ACCORDING TO GHOSH'S EQUATION AND THOSE CALCULATED ACCORDING TO THE IONIC THEORY.

$C \times 10^3$	2.	5.	10.	20.	50.	100.
$i_{\text{Ghosh}}$ .....	1.970	1.960	1.949	1.936	1.913	1.891
$i_{\text{Adams}}$ .....	1.969	1.961	1.943	1.922	1.888	1.861
$i_{\text{cond.}}$ .....	1.971	1.956	1.941	1.918	1.889	1.860

From the table it is evident that, at concentrations above 0.01  $N$ , the values as calculated from Ghosh's equation deviate systematically

<sup>7</sup> Ghosh, Ref. 5, p. 707.

<sup>8</sup> Adams, THIS JOURNAL, 37, 481 (1915).

from the determined values by amounts which are in excess of the experimental error. These deviations exceed 1% at 0.1 *N*. Another fact which argues strongly against the adequacy of Ghosh's equation is the fact that the values of  $i$  as determined from freezing-point measurements differ for different electrolytes at higher concentrations. Since the value of  $i$  as calculated from Ghosh's equation is the same for all electrolytes of the same type, it follows that the observed variation in the experimentally determined values of  $i$  are not accounted for by his theory. In the following table are given values of  $i$  for a number of binary electrolytes at a concentration of 0.1 *N*.

TABLE III.

VALUES OF  $i$  AT 0.1 *N* CONCENTRATION FOR DIFFERENT ELECTROLYTES IN WATER.

Salt.	KCl.	KNO <sub>3</sub> .	KIO <sub>3</sub> .	NaIO <sub>3</sub> .	LiCl.	KOH.	HCl.
$i$ .....	1.861	1.787	1.764	1.772	1.901	1.865	1.917

The values of  $i$  for the first four electrolytes are derived from the very exact determinations of Adams<sup>8</sup> and of Hall and Harkins,<sup>9</sup> while the remaining values are taken from the tables given by Noyes and Falk.<sup>10</sup> It is seen from this table that the extreme variation in the value of  $i$  is from 1.764 to 1.917. This variation in the value of  $i$  for different electrolytes at higher concentration cannot be ascribed to experimental error. It represents, in fact, a real difference in the properties of the solutions of these substances. Ghosh's theory, being founded upon the assumption that all electrolytes are completely ionized, is obviously unable to account for the divergence in the properties of different electrolytes of the same type. In the case of aqueous solutions, as has already been pointed out, the ionization curves for different electrolytes do not differ very greatly, but it is evident that the freezing-point curves differ to a much greater extent. We shall see that, in non-aqueous solvents, solutions of electrolytes of the same type differ very largely as regards their ionization values according to the conductance method also.

### 5. Non-Aqueous Solutions.

The most extensive material for testing the applicability of Ghosh's theory is found in conductance data relating to solutions in non-aqueous solvents. That Ghosh experienced some difficulty in attempting to apply his equations to solutions in non-aqueous solvents is evidenced by the fact that he was forced to assume more or less arbitrary types of ionization for solutions of simple binary salts. In the case of solutions of tetraethyl-ammonium iodide, for example, he assumes a ternary ionization of the type  $(MX)_2 = M_2^{++} + 2X^-$ . No independent evidence exists in support of this assumption. As we shall see below, this assumption

<sup>8</sup> Hall and Harkins, THIS JOURNAL, 38, 2658 (1916).

<sup>10</sup> Noyes and Falk, *ibid.*, 32, 1011 (1910).

does not suffice to account for the extremely varied behavior of solutions in non-aqueous solvents. Indeed, to one familiar with the properties of solutions in such solvents, it is at once evident that the theory will meet with great difficulties, for, according to Ghosh's Equation, the ionization in a given solvent at a given temperature is independent of the nature of the electrolyte, while the experimental data indicate that different electrolytes of the same type, even at low concentrations, exhibit a varying degree of ionization depending upon the nature of the electrolyte, as well as upon that of the solvent.

Below are considered solutions of typical salts in a few non-aqueous solvents. The number of examples might be greatly multiplied, but those which are presented suffice to bring out clearly the inadequacy of Ghosh's theory. The solutions chosen are those for which experimental data of a relatively high degree of precision are available down to comparatively low concentrations. In Fig. 1 is shown the curve for solutions of tetra-ethyl-ammonium iodide in epichlorohydrin.<sup>11</sup> The experimental curve is manifestly similar to that of potassium chloride in water. The characteristic deviations from Ghosh's equation, however, are more accentuated. Ghosh's calculated values, assuming a ternary ionization process, are represented on the figure by circles, a straight line having been drawn through them. Had a binary ionization process been assumed, the straight line corresponding to his equation would have been inclined much less steeply than the one drawn. It is evident that the deviations between the experimental and the theoretical curves are far in excess of any possible experimental error. A somewhat better agreement between the calculated and observed values at intermediate concentrations would be obtained by drawing a straight line tangent to the experimental curve in the neighborhood of the inflection point at approximately  $10^{-3} N$ . This line would be inclined more steeply than that due to Ghosh and would consequently correspond to a value of  $\beta$  greater than  $6.808 \times 10^3$ , which is that derived by Ghosh for a ternary ionization. But even in this case, at concentrations below  $10^{-3} N$ , the deviations between the observed and the calculated values would be far in excess of the experimental error. From the general form of the curve, also, it is evident that at higher concentrations the deviations would ultimately become marked. In the case of these solutions, however, experimental data are not available at higher concentrations. The value of  $\beta$  corresponding most nearly with the experimental curve is  $9.38 \times 10^3$ .

In Fig. 2 are plotted the results for solutions of potassium iodide in liquid ammonia according to the measurements of Franklin<sup>12</sup> and for tetra-propyl-ammonium iodide in ethylene chloride according to measure-

<sup>11</sup> Walden, *Z. physik. Chem.*, 54, 212 (1905).

<sup>12</sup> Franklin, *ibid.*, 69, 290 (1909).

ments of Walden.<sup>13</sup> Considering first solutions of potassium iodide in liquid ammonia, the discrepancy between Ghosh's theory and the experimental values is obvious. Down to concentrations as low as 0.001 *N*, the curve is distinctly convex toward the axis of concentrations. At somewhat higher concentration this convexity is extremely marked. This type of curve is characteristic of solutions in solvents of relatively low dielectric constant; that is, in the neighborhood of 20. In such solvents, at concentrations above 0.01 *N*, the equivalent conductance, in general, changes only very little with increasing concentrations; and, indeed, in certain cases increases with increasing concentration. At very

Fig. 2.—Plot of Ghosh's equation for KI in  $\text{NH}_3$  and  $\text{NPr}_4\text{I}$  in  $\text{C}_2\text{H}_4\text{Cl}_2$ .

low concentrations conductance measurements are not available in the case of potassium iodide in ammonia, but from the known similarity in the behavior of solutions of different electrolytes in ammonia at low concentration it is clear that, at concentrations slightly below 0.001 *N*, the experimental curve would be concave toward the axis of concentrations. This is clearly brought out in the case of potassium nitrate in ammonia, which is shown in Fig. 3.

The curve for tetra-propyl-ammonium iodide in ethylene chloride is much steeper than that of potassium iodide in ammonia. At the higher concentrations the curve is again convex toward the axis of concentrations, while at the lowest concentrations the curve is slightly concave toward this axis. The best straight line which could be drawn through the points of this curve would lie tangent to the curve in the neighborhood of the inflection point, passing through a point at about 0.001 *N*. This yields for  $\beta$  the value  $20.78 \times 10^3$ . It is clear, however, that the equation of Ghosh can reproduce the experimental results within the limits of error

<sup>13</sup> Walden, *Z. physik. Chem.*, **78**, 276 (1911).

only over an extremely small concentration interval in the neighborhood of the point through which the theoretical curve is arbitrarily made to pass.

According to Ghosh's theory, the ionization of electrolytes in a given solvent has the same value for all electrolytes of the same type under given conditions of temperature, pressure and concentration. It is known that the conductance curves of different binary electrolytes in liquid ammonia exhibit a great variety of form, even at comparatively low concentrations. For example, many of these curves intersect one another. This is not in harmony with Ghosh's theory in its present form. In Fig. 3 are shown the curves for potassium nitrate and silver iodide in liquid ammonia at its boiling point, the experimental values being due to Frank-

Fig. 3.—Plot of Ghosh's equation for solutions in  $\text{NH}_3$ .

lin and Kraus.<sup>14</sup> Considering first the curve for potassium nitrate, it is seen that at concentrations a little below 0.001  $N$  the curve is distinctly concave toward the axis of concentrations, while above this point the curve is convex toward this axis, having an inflection point in the neighborhood of 0.001  $N$ . Intersecting the curve for potassium nitrate are drawn two straight lines representing Ghosh's Equation for a binary and a ternary assumed ionization process. These curves correspond to the values  $\beta = 3.620 \times 10^8$  and  $6.808 \times 10^8$  respectively. A straight line drawn through the experimental curve, passing through the maximum number of points in the neighborhood of the inflection point, corresponds to a value  $\beta = 12.63 \times 10^8$ . The curve for silver iodide shown on the same figure exhibits a smaller curvature than does that of potassium nitrate, both at low and high concentrations. If a straight line is drawn in such

<sup>14</sup> Franklin and Kraus, *Am. Chem. J.*, 23, 277 (1900).

manner as to pass through the maximum number of experimental points, it is necessary to assume a value of  $\beta = 25.44 \times 10^3$ , in place of  $6.808 \times 10^3$ . A straight line corresponding to a ternary ionization is shown on the figure.

In order to account for the varied inclination of the curves for different electrolytes in ammonia solutions, according to Ghosh's theory, it would be necessary to assume a large variety of ionization processes, or of the relative distribution of the charges in the medium. The values following from a ternary ionization do not account for any of the results obtained with solutions in liquid ammonia. Here, in contrast to aqueous solutions, the individual characteristics of the electrolyte come clearly into view. According to Ghosh's theory, we should expect the conductance curves to fall into a few distinct classes. This, however, is not the case. It follows, therefore, that the agreement which Ghosh believes to have existed in the case of non-aqueous solutions is not substantiated, and that, in fact, assuming binary and ternary ionization processes, his theory does not account for the experimental results in such solutions even approximately.

## 6. The Temperature Effect.

Ghosh believes that his theory accounts for the effect of temperature on the ionization of electrolytes. In order to determine the correctness of this conclusion the conductance of solutions of potassium iodide in sulfur dioxide at  $-33^\circ$  and at  $+10^\circ$  have been examined, the results of Franklin<sup>15</sup> being employed for this purpose. The curves for these solutions are shown in Fig. 4. It will be observed that even at concentrations as low as 0.001 *N* the curves are markedly convex toward the axis of concentrations. As the concentration increases, the convexity of the curves increases markedly and, at the higher temperature, the curve exhibits a minimum, corresponding to the minimum in the conductance-concentration curve of these solutions. It is well known that this phenomenon is a general one which reappears in the case of all solutions in solvents having a dielectric constant lower than approximately 16. The lower the dielectric constant, the lower is, in general, the concentration at which the minimum point occurs; and, in solvents of very low dielectric constant, this minimum point lies as low as 0.01 *N* or lower. It is clear that, in the case of solutions of this type, Ghosh's theory does not apply even approximately.

The two straight lines, drawn through the points on the curve corresponding to a concentration of 0.001 *N*, represent Ghosh's equation for a ternary ionization process. The values of the constant  $\beta$  have been calculated from the dielectric constant of the solvent at the temperatures

<sup>15</sup> Franklin, *J. phys. Chem.*, 15, 675 (1911).

in question. The values of the dielectric constant were determined by extrapolation from the measurements of Eversheim.<sup>18</sup> These were found to be 15.1 at  $+10^\circ$  and 19.0 at  $-33^\circ$ . It is evident that, according to Ghosh's theory, the temperature can have only a small influence upon the ionization of an electrolyte in sulfur dioxide, since the value of  $\beta/DT$  at  $+10^\circ$  is 1.592; and at  $-33^\circ$ , 1.492. The two conductance curves, therefore, should be very nearly parallel, according to Ghosh. As indicated in the figure, however, this is not the case; moreover, the in-

Fig. 4.—Plot of Ghosh's equation for KI in  $\text{SO}_2$  at  $-33^\circ$  and  $+10^\circ$ .

clination of the two curves in the neighborhood of  $0.001 N$  differs much more than corresponds to the change in the value of  $\beta/DT$ . If straight lines are passed through the points in the neighborhood of  $0.001 N$ , they yield the values  $\beta = 13.63 \times 10^3$  at  $-33^\circ$  and  $19.44 \times 10^3$  at  $+10^\circ$ , while, according to Ghosh, the value of  $\beta$  should be constant and equal to  $6.808 \times 10^3$ . Assuming that Ghosh's theory yields a rough approximation to the actual facts, it is obviously necessary to assume that  $\beta$  is not a constant independent of the temperature but, on the contrary, one whose value depends on the temperature. This has an important bearing on the interpretation of Ghosh's theory.

#### 7. The Variation of the Constant $\beta$ .

According to the theory of Ghosh, the ionization curves for different

<sup>18</sup> Eversheim, *Ann. Physik*, [4] 8, 539 (1902).

electrolytes in a given solvent at a given temperature should fall into a small number of types, depending upon the number of charges associated with an ion and upon their relative distribution in the solvent medium. Since, according to this theory, the conductance curves should consist of a system of parallel straight lines for a given value of  $\beta$ , assuming the temperature to remain constant, it follows that, in the plots, the conductance curves should approximate a series of parallel straight lines. An examination of the curves for different electrolytes in liquid ammonia solution shows that this is not the case. Furthermore, it follows from the conductance curves of solutions of potassium iodide in sulfur dioxide at different temperatures that  $\beta$  is not a constant for a given electrolyte, but is a function of the temperature. Since, therefore, for a given electrolyte, there is a continuous shift in the value of  $\beta$ , with temperature change, it is necessary to assume a continuous displacement in the ionization process and in the nature of the assumed fixed spatial relations of the ions in the medium. But it is also clear that, for a given electrolyte at a given temperature in a given solvent, the curve is not linear, as required by Ghosh's theory. It follows, therefore, that  $\beta$  is a function both of temperature and of concentration.

The conductance of aqueous solutions of potassium chloride has been measured with a high degree of precision to concentrations as low as  $2 \times 10^{-5} N$ . The commonly assumed value of 130.0 for the limiting conductance of potassium chloride solutions can scarcely be in error by more than a few tenths of a unit. Assuming, therefore, this value of  $\Delta_0$ , we may calculate the value of  $\beta$  for these solutions at different concentrations. The change in the value of  $\beta$  will, of course, be affected by the value chosen for  $\Delta_0$ , but it is to be borne in mind that a variation must necessarily result in the calculated value of  $\beta$  at different concentrations, quite irrespective of the value chosen for  $\Delta_0$ . In general, it may be assumed that  $\beta$  will not both increase and decrease with change of concentration at low concentrations. This sets an upper limit to any possible value of  $\Delta_0$ . Whatever value may be chosen for  $\Delta_0$ , however, a change in the value of  $\beta$  is a necessary consequence of the experimental facts. In the following table are given the values for  $\beta$ , for potassium chloride in water at  $18^\circ$  at different concentrations.

TABLE IV.

VALUES OF  $\beta$  AT DIFFERENT CONCENTRATIONS OF POTASSIUM CHLORIDE IN WATER AT  $18^\circ$ .

Assuming  $\Delta_0 = 130.0$ .

$V$ .	$5 \times 10^4$ .	$2 \times 10^4$ .	$10^4$ .	$5 \times 10^3$ .	$2 \times 10^3$ .	$10^3$ .
$\beta \times 10^{-3}$ .....	1.578	1.678	1.700	1.757	1.954	2.201
$V$ .	$5 \times 10^2$	$2 \times 10^2$	$10^2$	50	20	10
$\beta \times 10^{-3}$ .....	2.384	2.526	2.874	3.049	3.260	3.833

It will be observed from this table that, as the concentration increases, the value of  $\beta$  increases markedly up to a concentration of 0.1 *N*. It is obvious, also, that in the case of non-aqueous solvents the variation of  $\beta$ , with increasing concentration, is much greater than it is in the case of aqueous solutions of potassium chloride. Furthermore, in solvents of low dielectric constant, the value of  $\beta$  at high concentration must ultimately decrease as the concentration increases, as may be seen from an inspection of the curve for potassium iodide in sulfur dioxide at  $+10^\circ$ , as shown in Fig. 4.

In the following table are given the calculated values of the constant  $\beta$  for solutions of typical salts in a number of different solvents, derived from the best straight line that may be drawn through the experimental points at low concentrations.

TABLE V.  
VALUES OF  $\beta$  FOR SOLUTIONS OF SALTS IN DIFFERENT SOLVENTS.

Solvent	H <sub>2</sub> O	epichlorohydrin	NH <sub>3</sub>	NH <sub>3</sub>	NH <sub>3</sub>	SO <sub>2</sub> (-33°)	SO <sub>2</sub> (+10°)	C <sub>2</sub> H <sub>4</sub> Cl
Electrolyte	KCl	NEt <sub>4</sub> I	KNO <sub>3</sub>	AgI	KI	KI	KI	NPr <sub>4</sub> I
$\beta \times 10^{-3}$	3.620	9.390	12.63	25.44	7.867	13.63	19.44	20.78

From an inspection of this table it is clear that  $\beta$  is in no sense a constant for solutions of different electrolytes in a given solvent, or for solutions of a given electrolyte in different solvents, or for a given solvent at different temperatures.

Those assumptions in Ghosh's theory which lead to the result that  $\beta$  is a constant are in contradiction with the experimental facts, and must, therefore, be modified or discarded. The actual determination of the value of  $\beta$ , according to Ghosh, depends on an evaluation of the potential of the field due to the ions. In order to evaluate this potential, he finds it necessary to ascribe to the ions not only certain definite charges, but also certain definite fixed positions in the medium. Since, now,  $\beta$  varies as a function of temperature and concentration, as well as of the nature of the solvent medium and the dissolved electrolyte, it follows that, in order to account for the variation in  $\beta$ , it is necessary to discard the assumption that the ions occupy a fixed position in the medium, independent of temperature and concentration. If this assumption is dropped, it obviously becomes impossible to calculate the potential due to the field of the ions in the medium, unless some other hypothesis is made with regard to the distribution of the charges. If the charges do not occupy a fixed position but a variable position dependent upon both temperature and concentration, it appears that we must necessarily revert to a kinetic interpretation of the state of the ions in the solution. The distribution of the ions, therefore, must be determined according to a kinetic hypothesis, taking into account the influence of the charges upon the distribution of the particles in the medium and their motion relative to one another.

### 8. Theoretical Considerations.

Ghosh assumes that all ions having a kinetic energy above a certain critical value are effective in transmitting the current through a solution. In determining the fraction of the ions having a velocity above a given value, he assumes Maxwell's law for the distribution of velocities.<sup>17</sup> The application of Maxwell's law of the distribution of velocities to a system of charged particles, and particularly to a system of charged particles, subject to restriction as regards their positions relative to one another, appears a doubtful procedure, since, at best, Maxwell's law of distribution cannot be expected to hold save in the case of systems free from constraints.

It is a weakness of Ghosh's theory that it is not able to render an account of those properties of electrolytes which depend on the nature of the electrolyte itself. This defect is inherent in the fundamental assumption that electrolytes are completely ionized and that the work involved in the ionization process is purely electrical in nature. That the work done against the electrical forces is a large factor in the ionization process is not to be doubted, but we have no certainty that electrical forces are the only ones involved. At any rate, it is very difficult to account for the properties of different electrolytes on the basis of this assumption. It would seem that the different ionization values for different electrolytes could be accounted for satisfactorily only by assuming forces other than of purely an electrical nature to exist between the various constituents present in the solution, or, rather, that the forces involved do not all obey the inverse-square law. The properties of electrolytic solutions appear to be much too varied in their nature to admit of being accounted for by hypotheses as simple as those underlying Ghosh's theory. While Ghosh has pointed out a method of attacking the problem of electrolytic solutions, it is necessary to modify his postulates as to the distribution of the charges in the medium and as to the determination of the number of carriers which are effective in transporting the current. The problem to be solved is to determine, by means of kinetic considerations, the equilibrium in a system of charged particles and electrical doublets.

In treating osmotic phenomena, Ghosh applies Clausius' Virial Theorem. This theorem leads to results of the first order of approximation only, in the case of ordinary gases, as has been pointed out by Jeans.<sup>18</sup> Its application to a system of charged particles subject to constraints is certainly open to question. At any rate, Ghosh's equation for  $i$  is not in harmony with experiment.

In calculating the potential due to the field in a solution of a binary

<sup>17</sup> Ghosh, Ref. 5, p. 450. Compare Chapman and George, *Phil. Mag.*, **41**, 799 (1921).

<sup>18</sup> Jeans, "Dynamical Theory of Gases," 2 Ed., p. 147.

electrolyte, Ghosh assumes the work necessary to separate a pair of univalent ions to be  $E^2/Dr$ , the medium between the particles being assumed to act normally. In determining, now, the work required to carry one mol of a binary electrolyte from its condition at a given concentration to a condition in which the particles are separated to such distances that the force between them may be neglected. Ghosh evaluates  $r$  on the assumption that positive and negative particles are distributed in a fixed manner throughout the solution, forming a cubical space lattice. From this he derives the expression

$$r = \left( \frac{V}{2N} \right)^{1/3};$$

and substituting this in the expression for the work above, and multiplying by  $N$ , the number of pairs of positive and negative particles, he evaluates the potential due to the assumed distribution of the charges in the medium. It appears, however, that in this procedure Ghosh has taken account of the work due to the separation of the  $N$  pairs of positive and negative particles in the solution, leaving out of account the forces acting between a given charge and all other charges. It is true that Ghosh assumes that the electrolyte forms doublets, but this assumption is inconsistent with the assumptions made in evaluating  $r$ , the distance between the charges.

### Summary.

1. The equation of Ghosh expressing the conductance of electrolytic solutions as a function of the concentration is compared with the experimental values in aqueous and non-aqueous solutions.

2. Plotting values of  $\log \Lambda$  against those of the cube root of the concentration, the experimental points lie upon a curve concave toward the axis of concentrations at low concentrations and convex toward this axis at high concentrations. If Ghosh's equation were applicable, the points should lie upon a straight line. The deviation of the points from a linear relation is consistent throughout, and cannot be accounted for by errors in the original observations. In its present form Ghosh's theory does not satisfactorily account for the properties of electrolytic solutions.

3. The postulates and assumptions underlying Ghosh's theory are briefly discussed, and some inconsistencies are pointed out.

**THE CONDUCTANCE OF CONCENTRATED SOLUTIONS OF  
SODIUM AND POTASSIUM IN LIQUID AMMONIA.**

BY CHARLES A. KRAUS AND WALTER W. LUCASSE.

Received September 10, 1921.

**1. Introduction.**

In a series of articles,<sup>1</sup> it has been shown that the conduction process in solutions of the alkali metals in liquid ammonia is ionic. The positive ion in these solutions is identical with the positive ion of a salt of the same metal, while the negative ion is apparently the negative electron. At low concentrations the negative electron is associated with ammonia, as a consequence of which its speed is of the order of magnitude of that of normal ions; for example, in sodium solutions the speed of the negative ion is 7 times that of the sodium ion. At higher concentrations, however, the carrying capacity of the negative ion increases. This is due to an increase in the speed of this ion in consequence of its loss of ammonia at higher concentrations. At very high concentrations, the speed of the negative ion in ammonia is comparable with that of the ions in metals, since the conductance of the metal solutions in ammonia reaches very high values. In previous investigations the conductance has been measured up to concentrations as high as 2.0 *N* with a preliminary observation on the conductance of a saturated solution of sodium in ammonia, the specific conductance of which is approximately one-half that of mercury. It is of interest to examine in detail the conductance curve in the concentrated regions, and, furthermore, to compare the conductance curves of different metals in this region. If the conductance of the concentrated solutions is due to the negative electron, which is therefore the same in solutions of different metals, then we might expect that the conductance curves of different metals in very concentrated solutions will resemble one another quite closely. In the present investigation the conductance of concentrated solutions of sodium and potassium has been studied.

**2. Method, Apparatus and Manipulation.**

Since the conductance of concentrated solutions of the metals in ammonia approaches that of mercury, it is obvious that special means must be adopted in order to measure its value. The ordinary methods, in which a pair of electrodes is introduced into a solution, obviously fail, since the resistance of these solutions is too low to be measured by such means. The apparatus finally employed in this investigation is the same as that employed by Kraus at an earlier date.<sup>2</sup> This apparatus is shown in outline in Fig.

<sup>1</sup> Kraus, *THIS JOURNAL*, 30, 1323 (1908); 36, 864 (1914); 43, 749 (1921).

<sup>2</sup> Kraus, *ibid.*, 43, 757 (1921).

1. The function of its various parts will, perhaps, be best understood by following the procedure in the case of a typical run.

Referring to the figure, Stopcock A connects the apparatus with a high vacuum system. On opening this cock, the entire apparatus, with the exception of the conductivity cell itself, which is shut off by means of the stopcocks B and C, is thoroughly

Fig. 1.—Outline of conductivity cell and measuring devices.

exhausted. When a sufficiently high vacuum has been obtained, this part of the system is filled with ammonia vapor which passes through K', L', Q and R from a supply cylinder, which is not shown in the figure but which is attached at D. The metal, the conductance of whose solutions is to be measured, is freshly cut and rolled into the form of cylinders of suitable size and introduced into the tube E with a glass weight F placed upon it. The tube is then sealed off at E and, after closing the stopcock G, the conductance cell is thoroughly evacuated through B. Stopcocks A, B, and G are then closed, C is opened, and the entire system is filled with ammonia from the supply tank. The stopcocks H, I and J are then closed, trapping ammonia in the tubes K, L, and M. Stopcock G remaining closed, A and B are opened, thus making connection with the vacuum system. When the conductance cell has been thoroughly evacuated, a bath of paraffin oil is placed around the lower part of the cell and that part of the tube E which contains the metal. The temperature of the bath is raised to about 10° above the melting point of the metal. When the metal is completely melted, the stopcock J is opened and ammonia is allowed to enter the tube E. Thus there is a slight pressure of ammonia gas in E which forces the metal through the capillary tube N into the conductance cell. In most cases this initial pressure is sufficient to force the metal through the capillary, but when this is not so, additional ammonia may be obtained from the chambers L and K and introduced into E in suitable amounts. As a rule, it is well to force the metal over with as small a pressure as possible in order to avoid spattering the molten metal on the upper walls of the cell. When the metal has been transferred, the last traces of ammonia are withdrawn with a pump, and the capillary is sealed off at O, while the filling tube OE is removed. When the sealing operation is concluded, the stopcocks A and B are shut off and the entire apparatus is filled with ammonia through C.

As was stated above, D is joined to a supply cylinder containing pure ammonia. In

preparing the solutions in the conductivity cell, ammonia is distilled from the supply cylinder into the measuring cell P, which has a capacity of approximately 5 cc. A vacuum-jacketed tube containing ammonia is placed around the cell P, while the stopcocks Q and R are kept closed and L' V and K' open. During this operation, connection with the conductance cell is shut off at C and G. The quantity of ammonia introduced into P, and later into the conductance cell, is measured along the scales on the tubes SS. These scales each have a capacity of about 0.5 cc. and are graduated in 0.01 cc. A third decimal place is obtained by estimating the tenths of the scale divisions. The measuring cells G' and F' are similar, except that one arm of these cells consists of a capillary. G' and F' have capacities of 1.25 and 2.5 cc. respectively.

After determining the volume of liquid in the measuring cell P, stopcocks T, G and V are closed and C and U opened, while the ammonia bath surrounding P is removed and replaced by a source of heat. At the same time the conductivity cell is surrounded by a bath of liquid ammonia. Under these conditions, ammonia evaporates in P and condenses on the metal in the conductivity cell. The purpose of the stopcock V is to force the boiling ammonia through the vaporizing chamber X and also to facilitate the boiling process. Without this stopcock, super-heating is liable to take place and, if the pressure becomes excessive, solvent may be lost either by blowing out one of the stopcocks or by blowing out through the mercury trap I'.

The initial quantity of approximately 5 cc. of ammonia condensed in the conductivity cell is not sufficient to bring the level of the liquid above the opening of the capillary Y. For this purpose, the cell is provided with a displacement cylinder which may be lowered by means of the external solenoid C'. The displacer consists of the glass cylinder A' which is connected by a glass rod to a glass-encased soft iron core B' which is suspended by means of a platinum-iridium spring. This device serves to raise the level of the liquid in the conductivity cell as well as to stir the solution in order to insure a uniform concentration throughout. With the displacement cylinder at its lowest position, the initial charge of ammonia is sufficient to fill the cell to a point where the electrodes are covered. The resistance of the liquid is measured in the glass spiral Y, consisting of 14 turns of capillary tubing, one end of which is connected to the cell at the point shown in the figure and the other end of which is connected to the lower extremity of the tube Z. One electrode, which consists merely of about 1.5 mm. of platinum wire, is introduced near the lower end of the tube Z, while another similar electrode is introduced near the lower end of the main chamber of the conductivity cell. Thus, the current passes through the solution in the cell and through the capillary whose length is approximately one meter and diameter somewhat less than a millimeter. The platinum electrodes are unplatinized, since these solutions do not polarize and platinum black tends to catalyze the reaction between the metal and the solvent. Copper leads are introduced into the wells D' and E' containing mercury, thus making connection with the platinum wires which serve as electrodes.

The resistance was measured by the usual Kohlrausch method, employing a small induction coil or an oscillator as a source of alternating current. The resistance of the lead system was carefully determined beforehand and allowed for in the final calculations.

Due to the difference in diameter of the tube Z and the capillary at N', bubbles of ammonia vapor are liable to form at this point. In order to avoid this difficulty at times, it is necessary to close the stopcock U and introduce a slight additional pressure upon the solution through T. The ammonia required to furnish this additional pressure is obtained from the measuring cell P, which has been filled in the meantime. The amount of ammonia so introduced is read off the graduated scales SS. When a satisfactory reading of the resistance of the initial solution has been obtained, ammonia is condensed in the cell G', the exact amount of liquid condensed being read off on the

graduated stem. This cell, like cell P, as well as the cell F', is provided with a vaporizing chamber and a control stopcock M', corresponding to V. The method of manipulation is entirely similar to that already described in connection with cell P. When a sufficient number of points have been obtained with volume additions of approximately 1.25 cc., ammonia is condensed in the cell F', whose volume is approximately 2.5 cc. After obtaining a number of observations with F' as measuring cell, the volume of the solution in the conductivity cell becomes sufficiently large so that further additions may be made directly from the cell P. The manometer I' serves to show the pressure under which ammonia is being condensed and also as a manometer for the purpose of determining the vapor pressure of the solutions. When a run is completed, the bath surrounding the conductivity cell is removed and the tip J' is broken off, thus allowing the ammonia in the cell to escape. At the same time a small amount of ammonia vapor is passed through C and U, and through the coil Y. By this means, the capillary is kept free from metal. Without this precaution, the capillary is filled with metal from which it can be freed only with great difficulty. When the ammonia has completely evaporated from the cell through J', this tip is again sealed, stopcocks C and G are closed, and the cell is thoroughly evacuated through B. When all traces of ammonia vapor have been removed, the tip J' is again broken and the tip O at the bottom of the cell is likewise broken off. Absolute alcohol, in the case of sodium, and absolute ether, with small additions of absolute alcohol, in the case of potassium, are then drawn into the conductance cell through O by suction applied at J'. By suitably manipulating the stopcocks B, G, C and U, the solvent may be drawn to any desired height in the cell or the capillary. When the metal has been completely dissolved, the cell is thoroughly washed with distilled water. The original solution of the metal, together with the wash waters, are combined, and the whole is titrated with standard acid.

The measuring cells were calibrated by first weighing empty and then filled with distilled water up to a height noted on the scale. In calculating the amount of ammonia used from cells F' and G', account was taken of the difference in the capillary rise of ammonia and water in the capillaries forming the right arm in each case. The volume of the capillary was also taken into consideration when the relative height of the liquid in the two arms was other than that at which the cell had been calibrated. Correction was also made for ammonia in the vapor space of the conductivity cell when this was found necessary.

The ammonia<sup>3</sup> was run directly into auxiliary cylinders having a capacity of 1 or 2 kg., into which about 3 g. of sodium had previously been introduced. After having withdrawn sufficient ammonia from the auxiliary cylinder so that it was practically free from hydrogen, the small supply cylinder mentioned above was connected to it and from 150 to 200 g. of ammonia was distilled into it. Previously, about 0.25 g. of sodium had been introduced into this cylinder also. As stated, this cylinder was joined to the apparatus at D. Thus the solvent was purified by being twice distilled from a sodium solution.

The sodium<sup>4</sup> was freshly cut before introducing into the tube E. By so doing, and by rapid manipulation, the formation of oxide is avoided. In the case of potassium it was found preferable to cut the metal under light petroleum ether.

One of the most probable sources of inconsistencies in the results is due to the possible lack of uniformity in the concentration of the solutions. Since the resistance changes very rapidly as the concentration changes, it follows that a slight change in the amount of ammonia in the capillary

<sup>3</sup> Obtained from the National Ammonia Company.

<sup>4</sup> From the Solvay Process Company.

Y would cause a considerable change in the measured specific conductance. This source of error was not completely eliminated and, in all likelihood, variations in the measured values obtained are due chiefly to this cause. This error may run as high as 1% for individual observations.

Since the density of the solutions is not known, the dilution  $V$  is expressed in liters of pure solvent per gram atom of metal. As the volume of the ammonia at its boiling point was measured directly, the density enters only in calculating corrections. For this the value 0.674 was assumed.

### 3. Calibration of the Conductance Cell.

The specific conductance of the solutions was determined by direct comparison of the resistance of the solutions with that of mercury. The mercury employed for this purpose was initially cleaned with sand, then with nitric acid, and finally it was twice distilled. The cell, after introducing the mercury, was placed in a bath of water at  $20^\circ$  and the resistance determined in the usual way. The resistance of the mercury in the capillary, after making correction for the resistance of the leads, was found to be 2.693 ohms at  $20^\circ$ . The specific conductance of the solutions at the boiling point of liquid ammonia was then calculated by means of the equation,  $l_x = R'l'/R_x$ , where  $l'$  is the specific conductance of mercury at  $20^\circ$ ,  $R'$  the resistance of mercury in the cell at  $20^\circ$ , and  $R_x$  the resistance of the solution in the cell at  $-33.5^\circ$ . When the cell is placed in liquid ammonia, the leads are at a temperature of  $-33.5^\circ$  at their lower extremity, while at room temperature at the top. Knowing the resistance of the leads and the temperature coefficient of the metal, correction was made for this effect. The specific conductance of mercury at  $20^\circ$  was assumed to be  $1.0444 \times 10^4$ .

### 4. Experimental Results.

The results obtained for the conductance of concentrated solutions of sodium and potassium in liquid ammonia are given in Tables I and II,

## 5. Discussion.

In Fig. 2 are shown values of the logarithms of the specific conductance of sodium solutions plotted as ordinates against values of the logarithms of the dilution plotted as abscissas. The values of Run 2 are represented by circles, those of Run 3 by crosses, those of Run 4 by combined circles and crosses, those of Run 5 by squares and those of Run 6 by broken crosses. In order to compare the results here obtained with those in the more dilute solutions previously measured by Kraus, a few values from the earlier investigation have been added on the figure, being represented as broken vertical lines. As may be seen, the two are in excellent agreement. In Fig. 3 the heavy curve passing through the points is that of potassium solutions, while that of sodium solutions is represented as a lighter line. Here, again, the results of Run 1 are represented by circles and those of Run 2 by crosses, while the earlier values of Kraus are represented by broken vertical lines.

The first few points on the curve at the highest concentrations lie on a horizontal straight line. These points give the conductance of solutions saturated with the metal. The points of intersection between the horizontal portions and the other branches of the curves represent saturated solutions. The concentrations of the saturated solutions may therefore be obtained from these curves. On making the necessary calculations

Fig. 2.—Conductance curve for solutions of sodium in ammonia.

it is found that one atom of sodium is dissolved in 5.367 molecules of ammonia, and that one atom of potassium is dissolved in 4.866 molecules of ammonia. The agreement with the determinations of Ruff and Geisel<sup>5</sup> is fairly good. Taking into account the difficulties involved in the direct determination of the solubility by the method of Ruff and Geisel, it would appear that the present results are the more reliable.

The value obtained for the specific conductance of the more concentrated solutions of sodium and potassium in liquid ammonia is a very striking result. The specific conductance of a saturated sodium solution is 5047.0, while that of a saturated potassium solution is 4569. The sodium solutions conduct slightly better than the potassium solutions. The specific conductance of mercury at 20° is  $1.044 \times 10^4$  from which it is evident that the value of the conductance of these solutions is comparable with that of the metals. However, in making such a comparison the values of the

<sup>5</sup> Ruff and Geisel, *Ber.*, 39, 828 (1906).

atomic, rather than those of the specific, conductance should be compared. In Table III are given values of the atomic conductance of various metals at 0° or near room temperatures.<sup>6</sup>

		Saturated sodium sol. <sup>b</sup> .....	0.6720

<sup>a</sup> Calculated on the assumption that the conductance of silver amounts to  $60 \times 10^4$ .

<sup>b</sup> Calculated on the assumption that the density of the solution is equal to that of the pure solvent. The density is actually less than that of the solvent. The value given for  $\Lambda$  is therefore less than the true one.

The atomic conductance of a saturated solution of sodium in liquid ammonia is  $0.672 \times 10^6$ . It is evident that the atomic conductance of saturated solutions of sodium and potassium in liquid ammonia is of the order of that of such metals as strontium and iron, and much greater than that of mercury and bismuth. If the conductance measurements could be extended into the supersaturated regions, it is evident, from the form of the curves, that much larger values of the atomic conductance might be expected. It is interesting to note that, as may be seen from the table, those elements which exhibit the highest atomic conductance all belong to the first group of elements. Among the elements having an atomic conductance greater than  $1.5 \times 10^6$ , all belong to the first three groups of elements, with the exception of rhodium, chromium and titanium.

The manner in which the conductance varies as a function of the con-

<sup>6</sup> Landolt-Börnstein "Physikalisch-Chemische Tabellen," 1912.

centration is very interesting. At the highest concentrations, the specific conductance increases approximately five fold, when the concentration is doubled. In this region, the relation between the specific conductance and the concentration may be expressed by an exponential equation, since the logarithm of the specific conductance varies very nearly as a linear function of the logarithm of the dilution, as may be seen from Fig. 2. At somewhat lower concentrations, the conductance curve is concave toward the axis of concentrations, after which it exhibits an inflexion point at about  $V=0.65$ . In this region the specific conductance of the solution increases enormously with the concentration. Between  $V=0.5933$  and

Fig. 3.—Comparison of conductance curves for potassium and sodium in ammonia.

$V=0.3393$  the conductance increases from 79.56 to 612.8 or nearly 10-fold, while between  $V=1.298$  and  $V=0.5933$  the conductance increases from 1.269 to 79.56 or more than 60-fold. In the neighborhood of  $V=0.67$  a concentration increase of 1% is accompanied by a conductance increase of approximately 15%. It is in these regions that the negative electrons are becoming free from the ammonia molecules with which they are associated in the more dilute solutions. At higher concentrations this factor is doubtless of smaller influence, and it is possible that a change in the total number of carriers present has a material influence on the conductance.

Very striking, is the great similarity of the curves for sodium and potas-

sium. Indeed, they almost coincide over a considerable range of the concentration interval. In the most concentrated solutions the conductance of potassium is somewhat lower than that of sodium. The two curves then coincide, after which again they diverge slightly at a value  $\log V = 1.7$ . Thereafter they again intersect and diverge slightly at lower concentrations owing to the greater conductance of the potassium<sup>7</sup> ions. Apparently, the specific conductance of the more concentrated sodium and potassium solutions is very nearly the same at the same equivalent concentration. When we take into account the fact that the densities of the two solutions probably vary appreciably<sup>8</sup> and that, furthermore, the solvation of the positive ions in all likelihood differs for the two metals, it is remarkable that the two curves should approach each other so closely. This is merely an expression of the fundamental fact that the conductance of these solutions is due to the same cause; namely, to the negative electron. It would appear from this, that both the number of electrons and the speed with which they move in these solutions is a function primarily of the equivalent concentration. Since it has previously been shown that the negative carrier in dilute solutions of different metals in ammonia is the same, and since it has been shown that the increase in conductance with increasing concentration is due to the increased speed of the negative carriers in these solutions, it follows that the conductance of the concentrated solutions is due to a common negative carrier, obviously the negative electron. Moreover, since the order of the conductance of these solution is the same as that of the metals, the conclusion appears justified that the conduction process in metals consists essentially in a motion of the negative electron.

## 6. Summary.

1. The specific conductance of solutions of sodium and potassium in liquid ammonia at its boiling point has been measured from concentrations in the neighborhood of normal up to the saturation point.

2. As the concentration increases, the specific conductance increases enormously, reaching the values  $0.5047 \times 10^4$  and  $0.4569 \times 10^4$  for saturated solutions of sodium and potassium respectively.

<sup>7</sup> Kraus, *THIS JOURNAL*, 43, 749 (1921).

<sup>8</sup> In respect to density, these solutions are most exceptional. While no exact quantitative data have yet been obtained, the order of magnitude of the volume change may be seen from the following observation. The level of the solution at the third point in the second run with potassium was noted and, when the run was completed, the volume of the cell up to this height was obtained roughly by filling it with water. The amount of metal was of course known and the volume of ammonia at this point was likewise known. From these data the density of this solution was calculated to be 0.632. How abnormal these solutions are is realized on noting that 2.48 g. of a solid of density 0.86 and 5.55 g. of a liquid of density 0.674 form a solution of density 0.632.

3. The specific conductance of solutions of sodium and potassium at the same equivalent concentration is very nearly the same.

4. The equivalent conductance of saturated solutions of sodium and potassium in liquid ammonia is of the order of magnitude of that of such metals as strontium and iron.

5. The solubility of sodium and potassium in liquid ammonia at its boiling point has been found to be 5.367 and 4.866 mols of ammonia per atom for sodium and potassium respectively.

6. The results of this investigation furnish further evidence in support of the hypothesis that the conduction process in metals consists in a motion of negative carriers of sub-atomic dimensions, which carriers are the same for all metals.

## THE PREPARATION AND PROPERTIES OF THE PERSULFIDES OF HYDROGEN.

BY JAMES H. WALTON AND LLEWELLYN B. PARSONS.

Received September 20, 1921.

### Introduction.

When an excess of hydrochloric acid is added to a solution of a polysulfide of an alkali or one of the alkaline earths, a yellow oily liquid separates. Since the time of Scheele, who first prepared this substance, much work has been done on its preparation and the study of its properties. Among the more recent investigators, the work of Rebs,<sup>1</sup> Bruni and Borgo,<sup>2</sup> and Bloch and Höhn<sup>3</sup> are worthy of note. The experiments of the latter authors are the most important in connection with this investigation. These investigators prepared the yellow oil by dissolving sulfur in a solution of sodium sulfide contained in a flask through which a stream of hydrogen was passed to prevent oxidation. The resulting solution was chilled and then run into a hydrochloric acid mixture consisting of one part of hydrochloric acid and one part of ice, surrounded by a mixture of ice and salt. Operating in this way they obtained a product with a density varying from 1.62 to 1.69. The yellow oil when subjected to fractional distillation, yielded two products which on analysis gave the empirical formulas  $H_2S_2$  and  $H_2S_3$ . Further experiments confirming the work of Bloch and Höhn were carried out by Schenck and Falcke.<sup>4</sup>

<sup>2</sup> Bruni and Borgo, *Gazz. chim. ital.*, **38**, 279, 292 (1907-8).

<sup>3</sup> Bloch and Höhn, *Ber.*, **41**, 1961 (1908).

<sup>4</sup> Schenck and Falcke, *Ber.*, **41**, 2600 (1908).

The object of the present investigation was to improve the method for the preparation of the pure persulfides, and to study the chemical and physical properties of these compounds.

### Experimental.

**Preliminary.**—To determine the effect of the common acids on a solution of sodium polysulfide, a solution of this substance similar to that used in the following experiments was prepared. This was cooled and slowly run into solutions of acetic, phosphoric, sulfuric, and hydrochloric acids respectively. Hydrochloric acid brought about the formation of the yellow oil; the other acids gave complete decomposition into sulfur and hydrogen sulfide.

**The Preparation of the Crude Persulfide.**—The methods given in the literature for the preparation of this substance are vague and difficult to repeat, many essential details being omitted. As a consequence, the modified method used by the authors is given in detail. Two kg. of commercial C. P. sodium sulfide crystals was placed in a 3-liter round-bottomed flask, 300 g. of flowers of sulfur added, and the two thoroughly mixed. Eight hundred cc. of water, enough to dissolve completely the resulting polysulfide at room temperature was then added. The flask was closed with a Bunsen valve, which obviates the necessity of passing hydrogen through the solution, and then heated on a water-bath for from 3 to 4 hours with occasional shaking. At the end of this period all the sulfur was dissolved. This polysulfide solution can be kept in a tightly stoppered vessel for several weeks without deteriorating sufficiently to influence the subsequent operations.

Preliminary experiments showed that cold hydrochloric acid, sp. gr. 1.19, was satisfactory for decomposing the sodium polysulfide. The cooling and rate of bringing the two solutions together are of great importance. Fig. 1 illustrates the apparatus used for this purpose. A and A' are galvanized iron containers insulated by excelsior. C is a specimen jar, diameter 25 cm. This was surrounded by a mixture of ice and salt. Three liters of the concentrated acid was placed in the jar and agitated with a stirrer driven at the rate of about 100 r. p. m. To aid in the cooling a few pieces of ice were always kept in the hydrochloric acid solution. During the reaction the temperature of the hydrochloric acid was kept between  $-4$  and  $-10^{\circ}$ . The sodium polysulfide was added from E at a rate of about 3 liters per hour. Attention is called to the necessity of adding the polysulfide below the surface of the hydrochloric acid, this procedure minimizing the decomposition of the hydrogen persulfides. After about a liter and a half of the sodium polysulfide had been added, the persulfides began to rise in the form of a dark brown scum, and decompose with the evolution of hydrogen sulfide. At this point the addition of sodium

polysulfide was stopped, the specimen jar was replaced with one containing a fresh portion of hydrochloric acid, and the operation continued until all the sodium polysulfide had been added. The persulfides, which were now largely present as an emulsion, settled on the bottom of the container in about 2 hours. This liquid was separated by means of a separatory funnel and washed several times with cold distilled water. In general 2 kg. of sodium persulfide gave a yield of between 400 and 500 cc. of the crude product.

In drying the crude product obtained above, fused calcium chloride, previously treated with dry hydrogen chloride, had been used by previous investigators. Whenever the calcium chloride was used in this investigation, an appreciable amount of decomposition of the persulfides took place with the evolution of large amounts of hydrogen sulfide.

Phosphorus pentoxide has no action on the persulfides and so was used to dry them. Several g. of this substance was allowed to stand in contact with the yellow liquid for a day or two with occasional shaking. At the end of that time the phosphorus pentoxide was removed by filtering through asbestos on a Büchner funnel. Fused powdered boric oxide may also be used to dry the yellow oil. This substance is inconvenient to prepare and offers no advantages over the phosphorus pentoxide. Analysis of the crude product prepared in this way showed that on decomposing it yielded between 19 and 21% of hydrogen sulfide. The compound  $H_2S_8$  evolves 20.98% of hydrogen sulfide. It is believed, however, that this crude product is a solution of sulfur in equilibrium with various sulfides of hydrogen and not a definite compound. This point will be the subject of further investigation.

**Analysis of the Persulfides.**—No rapid and accurate method for analyzing the persulfides has been described. Among those used may be mentioned (1) the decomposition of the persulfides by heat with subsequent determination of the hydrogen sulfide formed, (2) solution of the persulfide in an organic solvent such as toluene, addition of standard iodine and titration of excess of the iodine, (3) determination of the hydrogen by combustion and the sulfur by the Carius method. The published results of analyses by these methods are far from satisfactory.<sup>8</sup> A long series of

Fig. 1.—Apparatus for preparation of persulfide.

experiments carried out to test Method 2 failed to give concordant results. In the analysis of the persulfides by the determination of the total hydrogen and the sulfur present, small experimental errors introduce very large errors in the empirical formulas computed. The method finally adopted consisted in dissolving a weighed amount of the hydrogen persulfide in carbon disulfide, adding acetone to decompose the persulfide, removing the acetone, carbon disulfide and hydrogen sulfide by evaporation, and weighing the sulfur. The hydrogen sulfide was then found by difference. The details of this method are as follows. Two to three g. of the sample was placed in a tared 75mm. quartz test-tube which was then corked and weighed at once. The tube was nearly filled with carbon disulfide, the contents poured into a tared 75mm. crystallizing dish and the tube washed out with the disulfide. The total volume of disulfide used was 20 to 30 cc. About 10 cc. of pure acetone was then added to the solution and the crystallizing dish covered with a watch glass. After the evolution of gas had ceased, the watch glass was rinsed with disulfide and the solution allowed to evaporate spontaneously, the process being complete in 3 to 4 hours. The residue of rhombic sulfur crystals was dried to constant weight at 90°.

A blank run made by evaporating 50 cc. of the mixed disulfide and acetone gave no weighable residue. The following table shows that the results obtained by this method are independent of the size of the sample and the volume of carbon disulfide used. Ten cc. of acetone was used in each case.

	1.	2.	3.
CS <sub>2</sub> , cc.....	25	50	75
Sample, g.....	2.2945	3.2243	2.1412

H <sub>2</sub> S in sample, %.....	19.48	19.58	19.49

This extremely accurate and rapid method was used in all the analyses made in this investigation.

**Distillation of the Persulfide.**—The distillation of the crude persulfide yields the compounds H<sub>2</sub>S<sub>2</sub> and H<sub>2</sub>S<sub>3</sub>. The apparatus described by Bloch and Höhn may be used for this purpose; the yields obtained, however, were very unsatisfactory. Ordinary glass decomposes the persulfides of hydrogen, the action being due to the alkali in the glass. At temperatures necessary for distillation the decomposition is considerable. Several investigators have decreased this decomposition by treating the glass with hydrochloric acid. The advantage of quartz apparatus for distillation and also for preservation of the persulfides of hydrogen is shown by the following experiment. A quantity of the crude persulfide was placed in a small Pyrex flask that had been treated with hot conc. hydrochloric acid and dried by passing a stream of dry hydrogen chloride through it. An

equal quantity of persulfide was placed in a clean dry quartz flask and the two allowed to stand under similar conditions for several days. In less than a week the persulfide in the Pyrex flask had decomposed to such an extent that crystals of sulfur were deposited. No sulfur crystals were deposited in the quartz flask after standing for a month.

The apparatus used in Fig. 2 is similar in principle to that of Bloch and Höhn. As far as possible quartz was used in its construction.

B is a 250cc. quartz distilling flask. The inner tube of the condenser, E, is of hard glass, 8 mm. outside diameter. C is a 300cc. quartz flask fitted with a 2-holed paraffined rubber stopper. By means of a hard glass tube it is connected with a 20cm. quartz test-tube which is also fitted with a paraffined rubber stopper. A is a 500cc. hard glass distilling flask.

In carrying out the distillation the flask B was heated to 120° in a glycerine bath and the system exhausted by means of a vacuum pump to a pressure of 3 to 5 mm.

C was cooled by the water from the condenser which ran out through a Y-tube. D was cooled in the first experiments by solid carbon dioxide and ether as described by Bloch and Höhn. Salt and ice mixture was found to be quite satisfactory, however, and this mixture was used in

Fig. 2.—Distilling apparatus for persulfides.

the later experiments. Ten to 15 cc. of the crude persulfide was run into B through the separatory funnel, F, whereupon the persulfides began to distil slowly. After 10 minutes the residue in B consisted mainly of sulfur dissolved in persulfide. This was removed by closing the cock  $S_1$  and opening  $S_2$ , whereupon the residue was drawn over into A. Inasmuch as this residue solidifies on cooling, the tube *t* had to be carefully heated during this operation. After the residue had been removed from the flask,  $S_1$  was closed,  $S_2$  opened, more persulfide added, and the distillation carried on as before.

The yield by distilling the crude product depends upon many factors, the most important of which is the age of the sample. Two volumes of the freshly prepared persulfides usually gave 1 volume of distillate;  $\frac{2}{3}$  of this was hydrogen trisulfide and  $\frac{1}{3}$  hydrogen disulfide.

In the later experiments it was found that a vacuum of 20 to 25 mm. could be used in the above distillation; as a consequence a water suction pump can be used with entire satisfaction.

**Hydrogen Trisulfide.**—This substance collects in Receiver C in a high state of purity, as is shown by the following results of analysis.

Hydrogen trisulfide is a mobile, yellow, oily, liquid with an odor similar to that of camphor and sulfur monochloride. Its vapors attack the eyes and nose strongly. On cooling the trisulfide, the yellow color disappeared, this behavior being exactly analogous to that of yellow rhombic sulfur which becomes pure white at the temperature attainable with solid carbon dioxide snow and ether. The trisulfide was soluble in benzene, toluene, chloroform, carbon disulfide, ether, and heptane, while alcohols, ketones, nitrobenzene, aniline and pyridine caused it to decompose catalytically. In any of the above mentioned solvents it was noted that small quantities of impurities caused the trisulfide to decompose with the deposition of white gleaming crystals of nacreous sulfur which, on standing changed rapidly into ordinary rhombic sulfur.

To determine the melting point of the trisulfide, some of it was cooled in a bath of carbon dioxide snow and ether to a temperature of  $-78^{\circ}$  as registered on a toluene thermometer. On cooling, the trisulfide behaved like a glass, becoming more and more viscous, until solidification took place. No definite melting point was noted. The quartz tube containing the trisulfide was removed from the freezing mixture and allowed to warm up slowly. The thermometer remained constant for about a minute at  $-52^{\circ}$  to  $-53^{\circ}$ . This is the melting point of the trisulfide as given by Bloch and Höhn.

The hydrogen trisulfide distilled readily in the vacuum apparatus, with little or no foaming. In one case 100 cc. of the trisulfide was distilled and not more than 10 cc. of the sulfur and persulfide residue was left behind in the distilling flask. About 15 cc. of the disulfide was obtained at the same time.

Attempts were made to distil the trisulfide under atmospheric pressure. A small quartz still with ground joints was available; this was fitted with a small quartz condenser. Ten cc. of the compound was placed in the distilling flask and carefully heated. The whole mass foamed, evolving hydrogen sulfide, and leaving behind a thick gummy solution of sulfur in persulfide. One or two drops of distillate were obtained, but it was never possible to obtain a sample of sufficient size for analysis.

**Hydrogen Disulfide.**—In the second container, cooled with a mixture of carbon dioxide snow and ether, a compound of the approximate composition H<sub>2</sub>S<sub>2</sub> collected. The compound obtained never showed by analysis

the composition  $\text{H}_2\text{S}_2$ , being always 1 or 2% low in hydrogen sulfide content. The following is a typical analysis.

	1.	2.
Sample, g.....	3.4490	3.2283
Sulfur residue, g.....	1.7340	1.6220
$\text{H}_2\text{S}$ , g.....	1.7150	1.6063
% $\text{H}_2\text{S}$ .....	49.72	49.76
$\text{H}_2\text{S}$ calc. in $\text{H}_2\text{S}_2$ %.....	.....	51.20

These results indicated that the disulfide contained some dissolved trisulfide. This led to an attempt to distil the sample, obtained in the vacuum distillation, at ordinary pressures. The small quartz still, previously employed for the attempted distillation of the trisulfide, was used. Some of the disulfide was placed in the still, which was heated carefully with a micro burner. The disulfide distilled without foaming or bubbling, and was readily condensed in the small condenser which was kept at a temperature of about  $15^\circ$  by running water. The disulfide did not all distil, about  $\frac{1}{6}$  of the original volume remained behind as a gummy viscous mass. Samples of the distillate were collected directly in the quartz weighing tube and analyzed immediately. The following results were obtained.

	1.	2.
Sample, g.....	1.9172	2.0351

Hydrogen sulfide, in $\text{H}_2\text{S}_2$ , %.....	.....	51.20

The hydrogen disulfide was a practically colorless mobile oil with a much more severe and irritating odor than the trisulfide. When the disulfide was being distilled under atmospheric pressure the vapors were extremely irritating, causing tears and a smarting sensation in the nostrils. The disulfide dissolved in the same solvents as the trisulfide; it was, however, much more sensitive to small amounts of impurity than the latter. This was especially noticeable when acetone was added to the carbon disulfide solution in the analytical procedure. It was consequently necessary to be very cautious in adding the acetone in order not to have the hydrogen sulfide evolved so rapidly that the liquid would bubble over.

The boiling point of the disulfide was determined by placing some of the distilled product in a small quartz tube equipped with a two-holed rubber stopper carrying a sensitive thermometer. On gently heating, the disulfide boiled at  $74.5^\circ$ , checking the value obtained by Bloch and Höhn.

The melting point of the disulfide was determined by a method similar to the one used for the trisulfide; the cooling agent used was liquid air. The slowing up in the rise of the toluene thermometer used came at  $-88^\circ$  to  $-90^\circ$  in several trials. The disulfide behaved like the trisulfide on cooling, showing no sharp solidification point.

**Action of Trisulfide Solutions on Inorganic Salt Solutions.**—Because of the extreme ease of decomposition of the disulfide, the trisulfide was used in the experimental work which follows. The action of an ether solution of the trisulfide on solutions of various inorganic salts dissolved in the same solvent was tested. As a check on the experiments, similar solutions of the salts were treated with a saturated ether solution of hydrogen sulfide. Copper oleate gave a red-brown colloidal precipitate; ferric chloride solution gave a white precipitate, which redissolved; stannic iodide gave a buff precipitate; silver nitrate gave no change; mercuric bromide gave a yellow precipitate. In every case the saturated ether solution of hydrogen sulfide gave a similar result. It was concluded that the behavior of the trisulfide in ether solution is essentially the same as that of hydrogen sulfide.

**Action of the Trisulfide on Metallic Oxides and Oxidizing Agents.**—The effect of adding small amounts of the trisulfide to a number of metallic oxides was observed by pouring some of the trisulfide upon a small amount of the oxide placed on a carefully cleaned watch glass.

Silver oxide, copper oxide, lead peroxide and mercuric oxide caused violent decomposition of the trisulfide; the heat evolved was sufficient to ignite the persulfide.

Lead oxide, stannic oxide and magnetite brought about a violent decomposition of the trisulfide.

Arsenious oxide, arsenic oxide, ferric oxide, zinc oxide, barium peroxide and manganese dioxide caused only a slow decomposition.

The oxidizing agents potassium permanganate and potassium dichromate were found to decompose the trisulfide rapidly. The permanganate generated sufficient heat to ignite the persulfide.

**Action of the Trisulfide on Inorganic Salts.**—A number of salts were treated with small amounts of the trisulfide. The sulfates of ferrous iron, aluminum, nickel, zinc and manganese gave a very slow decomposition of the trisulfide. Anhydrous copper sulfate, however, decomposed the trisulfide rapidly, the whole mixture turning dark.

The nitrate of aluminum gave only a slow decomposition while the nitrates of lead, silver and copper caused a rapid decomposition of the persulfide. Ferric nitrate behaved in a peculiar manner; for a time no visible decomposition took place and then suddenly an increasingly violent reaction began, as if it were an autocatalytic effect.

The chlorides of manganese, sodium, cadmium, ammonium and lead decomposed the trisulfide only slowly. The chloride of antimony dissolved with the consequent decomposition of the trisulfide. The chlorides of copper and lead turned dark with accompanying decomposition of the trisulfide.

The acetate, bromide and oleate of copper decomposed the trisulfide

rapidly turning dark at the same time. Antimony tri-iodide dissolved in the persulfide. The mixture turned red and decomposed.

Massive metals did not decompose the persulfide rapidly. They became coated with the sulfide of the metal and the reaction ceased. Powdered arsenic, antimony and zinc and iron, however, brought about rapid decomposition.

It was found that the persulfide was not decomposed by finely ground quartz which had been washed with hydrochloric acid and carefully dried. Neither did boric oxide nor phosphorus pentoxide bring about decomposition. It is to be noted that all copper salts decompose the persulfide as do most lead salts.

In order to see whether it would not be possible to dissolve some of the sulfides of copper and arsenic in the pure hydrogen trisulfide and thus obtain the free sulfo acids of these metals, a small amount of freshly precipitated, well washed and dried copper sulfide was added to the trisulfide contained in a quartz tube. The sulfide did not dissolve in the persulfide and was filtered off. A similar result was obtained with fresh arsenic trisulfide.

**The Decomposition of Hydrogen Trisulfide in a Sealed Tube.**—To observe the behavior of the trisulfide under pressure, some of it was sealed in a thick glass tube which had been scrupulously cleaned and carefully dried with hydrogen chloride. The hydrogen sulfide content of the sample was 34.4%. The sealed tube was allowed to stand in a hood under ordinary laboratory conditions. At the end of 3 days small crystals of sulfur began to appear, while at the end of 5 days there were two liquid layers noticeable, the one heavy and viscous, the other light, mobile and colorless, presumably hydrogen sulfide. There were large crystals of sulfur in the tube. After 2 days more, the viscous layer had completely disappeared and the tube contained only several large rhombic crystals of sulfur and liquid hydrogen sulfide, with possibly dissolved persulfide.

**Solubility of Hydrogen Trisulfide in Hydrogen Sulfide.**—Bruni and Borgo state that hydrogen sulfide is insoluble in the persulfides. They claimed to have liquefied hydrogen sulfide and found that the persulfide did not dissolve therein. In order to establish this fact definitely, hydrogen trisulfide ( $\text{H}_2\text{S}$  content 34.4%) was carefully introduced into a clean, heavy-walled tube. The tube was placed in a freezing mixture of carbon dioxide snow and ether. By passing a current of hydrogen sulfide into the cooled tube, the gas could be easily liquefied. About two volumes of the liquid hydrogen sulfide was collected above the trisulfide and the tube was sealed off. As soon as the trisulfide melted it completely dissolved in the hydrogen sulfide. On warming to room temperature, the solution was a pale straw color. When the tube stood for 5 days large crystals of rhombic sulfur separated, but there was no separation at any time of the persulfide such as was noted in the previous case when hydrogen

trisulfide alone was sealed off. Bruni and Borgo never obtained hydrogen trisulfide, so possibly, working with persulfides containing much dissolved sulfur, the liquid hydrogen sulfide might not dissolve the compounds completely. The previously noted fact that the trisulfide alone gave a layer of liquid hydrogen sulfide and also a layer of the persulfide containing dissolved sulfur, would point to this explanation as being the correct one for Bruni and Borgo's results.

**Solubility of Sulfur in Hydrogen Trisulfide.**—To determine the amount of sulfur which would dissolve in the trisulfide, several samples of trisulfide were saturated with sulfur and the hydrogen sulfide content of the solution obtained. Sulfur dissolved until the hydrogen sulfide content of the system was between 8 and 9%. The temperature of the samples varied between 17° and 20°. Calculated on the basis that all the hydrogen sulfide was present as the trisulfide one mole of the trisulfide dissolved 8 moles of sulfur.

### Summary.

1. The conditions under which pure hydrogen disulfide and hydrogen trisulfide may be prepared in quantity have been determined.
2. A new method for analyzing the persulfides of hydrogen has been devised. This method is rapid and accurate.
3. The hydrogen persulfides decompose most slowly when stored in quartz vessels.
4. The persulfides of hydrogen are decomposed catalytically by many substances, both inorganic and organic. Of the latter, ketones, aldehydes, alcohols, amino substitution products and nitro derivatives are specially effective.
5. It has been shown that hydrogen trisulfide and liquid hydrogen sulfide are miscible, thus disproving the statement of Bruni and Borgo to the contrary.
6. Hydrogen disulfide freezes at a temperature between  $-88^{\circ}$  and  $-90^{\circ}$ .

## A SEPARATION OF GERMANIUM AND ARSENIC.

By JOHN H. MÜLLER.

Received October 3, 1921.

In a recent publication on the atomic weight of germanium,<sup>1</sup> the author has called attention to the difficulties experienced in removing the last traces of arsenic from germanium. The distillation process from aqueous hydrochloric acid in the presence of chlorine which has been recommended did not give sufficiently accurate results as the distillate was at no time free from small quantities of arsenic.

Careful regulation of the temperature and maintenance of a low concentration of hydrochloric acid will give a distillate almost free from arsenic, but under these conditions the volatilization of the germanium is very slow or incomplete.

As the distillation from hydrochloric acid completely separates germanium from all metals and semi-metals other than arsenic, the complete removal of the latter element is all that is needed for the accurate analysis of germanium-bearing material.

A study of the relative physiological action of the derivatives of arsenic and germanium made necessary the detection and separation of small quantities of arsenic in the presence of large quantities of germanium.

Germanium dioxide was found to be non-toxic, and solutions of the same substance, when introduced subcutaneously, show a marked erythropoietic action.<sup>2</sup> It may be of interest to note that the peculiar likeness of germanium to arsenic, especially the solubility of the dioxide, suggested the study of its physiological action and that its non-toxicity links it with the non-poisonous oxides in its periodic group. In working up some 300 g. of impure germanium dioxide a separation of these closely associated elements has been found possible through a difference in their behavior toward hydrogen sulfide in presence of hydrofluoric acid.

The purpose of this paper is to describe this method.

### Experimental.

The germanium dioxide employed was some of the material used in the recent determination of the atomic weight of germanium. It was necessarily free from arsenic and other impurities

Approximately 5 g. of germanium dioxide was fused in platinum with sufficient sodium carbonate to form the normal sodium salt, the melt was dissolved in water, made up to 1 liter and the exact concentration of the solution determined by taking the mean of three analyses of 50cc.

<sup>1</sup> Müller, *THIS JOURNAL*, 43, 1085 (1921).

<sup>2</sup> Details to appear in *J. Exp. Med.*, 35, Feb. (1922).

samples. One liter of this solution contained 4.9640 g. of the dioxide. Dilution of this solution (A) to 0.1 and 0.01 concentration gave Solutions B and C respectively.

The arsenic trioxide was prepared by fractionation and resublimation of the nearly pure oxide. The standard arsenic trioxide solution was prepared like that for germanium and the concentration determined by three determinations of the trioxide as magnesium pyro-arsenate. One liter of this solution contained 4.8506 g. of arsenic trioxide. Dilution of this solution (A) to 0.1 and 0.01 concentration gave Solutions B and C respectively.

Definite portions of these solutions, in quantities shown in the table, were introduced by pipet into platinum dishes and after addition of hydrofluoric acid the solutions were saturated with hydrogen sulfide.

The hydrofluoric acid used was carefully examined and found free from iron, arsenic, silica and all metals precipitated by hydrogen sulfide.

The precipitated sulfide of arsenic was in each case filtered through filter paper in a platinum funnel upon which the sulfide was washed, first with hydrofluoric acid saturated with hydrogen sulfide and then with pure water until the washings were approximately neutral. The sulfide was then removed from the paper by dil. ammonium hydroxide and the solution evaporated in quartz. Pure conc. nitric acid was added and after evaporation of the excess of acid the arsenic was determined in the usual manner as magnesium pyro-arsenate. Porcelain Gooch crucibles with asbestos mats were employed. The acid filtrates containing the germanium, which were collected in platinum dishes, were treated with 10 cc. of pure conc. sulfuric acid and evaporated upon water-baths until nearly all of the hydrofluoric acid was expelled. The residual acid was then more strongly heated until the fuming of the residual sulfuric acid just began. When much germanium was present the dioxide tended to separate in an adherent layer on the bottom of the dish, but after diluting with water and making alkaline with ammonium hydroxide the whole was easily transferred to a glass vessel. The solution was then neutralized by addition of hydrochloric acid and sufficient excess of concentrated acid added to bring the concentration of free acid to 15–20% by weight. Hydrogen sulfide passed through this solution gave all the germanium as sulfide.

Care was taken, of course, to wash the germanium sulfide with strongly acidulated wash-water which had been thoroughly saturated with hydrogen sulfide, finishing the washing with very little cold water saturated under pressure with the same gas. The germanium was weighed as dioxide. Frequent treatment of the slowly ignited sulfide with pure nitric acid and subsequent evaporation and ignition were carried out to constant weight.

In several preliminary experiments the delicacy of the reaction of hydrogen sulfide upon hydrofluoric acid solution of arsenic trioxide was determined. It was found that as little as 0.0002 g. of arsenious oxide will be deposited as a visible precipitate from a solution containing 100 cc. of water and 50 cc. of 48% hydrofluoric acid and that this reaction may best be carried out in the cold.

A blank experiment was made with a solution containing 10 g. of germanium dioxide converted to fluoride in the presence of the 2NaF equivalent and 50 cc. of hydrofluoric acid and 300 cc. of water. Hydrogen sulfide had no effect upon this solution. The introduction of less than 0.001 g. of arsenic trioxide into a similar germanium solution gave all of the arsenic as sulfide after saturation with hydrogen sulfide. It was therefore concluded that the delicacy of this reaction for arsenic is not measurably influenced by large quantities of germanium fluoride, fluogermanic acid or the alkali salts of the latter.

The following table shows the results of eight analyses of mixtures of the oxides of germanium and arsenic. Numbers 8 and 9 are especially significant insofar as they show the possibility of separating 0.02 to 0.01% of arsenic from germanium compounds.

TABLE I.  
SEPARATION OF GERMANIUM AND ARSENIC.

Analysis.	Germanium dioxide present. G.	Arsenic trioxide present. G.	Germanium dioxide found. G.	Arsenic trioxide found. G.	Conc. hydrofluoric acid in solution (48%). Cc.	Total volume of solution. Cc.
1	0.2482	0.2425	0.2479	0.2420	50	150
2	0.2482	0.0243	0.2483	0.0234	50	100
3	0.2482	0.0024	0.2484	0.0040	50	150
4	0.2482	0.0005	0.2487	0.0004	30	110
5	0.0049	0.4851	0.0057	0.4841	55	160
6	0.0010	0.4851	0.0011	0.4839	51	152
7	10.0006	0.0020	not determined	0.0017	50	350
8	10.0002	0.0010	not determined	0.0010	50	150

### Summary and Conclusion.

1. Hydrogen sulfide is without action upon solutions of fluogermanic acid and the alkali salts of this acid.

2. Arsenic and germanium can be quantitatively separated by the action of hydrogen sulfide upon a solution of their oxides in the presence of a large excess of hydrofluoric acid.

3. The separation is sufficiently accurate to determine as little as 0.01% of arsenic in germanium compounds.

4. The method is especially useful in connection with the preparation of pure germanium compounds, as the fractional crystallization of the

double fluoride can thus be avoided and the operation carried out in small volume. The precipitation of the arsenic sulfide is complete and rapid in the cold.

## THE CO-PRECIPITATION OF VANADIC ACID WITH AMMONIUM PHOSPHOMOLYBDATE.<sup>1</sup>

By J. R. CAIN AND J. C. HOSTETTER.<sup>2</sup>

Received October 6, 1921.

### 1. Introduction.

In 1912 there was developed in this laboratory a method for the determination of vanadium in which this element was separated from other materials by co-precipitation with ammonium phosphomolybdate. In the paper<sup>3</sup> describing this method no details of the mechanism of this reaction were given. The purpose of the present paper is to discuss an investigation of the mechanism of the co-precipitation of vanadic acid with the ammonium phosphomolybdate in order to define better the conditions upon which the success of the procedure as an analytical method depends and, incidentally, to throw light upon the formation of vanadophosphomolybdates and to indicate that a simple relation exists among the many members of this class of so-called "complexes."

The method, as published, is in brief outline as follows. The hot nitric acid solution containing the vanadium as vanadic acid is nearly neutralized with ammonium hydroxide, and phosphorus (as sodium phosphate) is added in an amount at least ten times that of the vanadium suspected to be present. The phosphorus is then precipitated as ammonium phosphomolybdate and the resulting precipitate is washed with ammonium hydrogen sulfate solution. Finally, the vanadium is determined by dissolving the precipitate in conc. sulfuric acid, reducing with hydrogen peroxide, and titrating with permanganate. Except for the changes of conditions made necessary in order to study the problem advantageously, this general method was adhered to in all the experiments that follow.

### 2. Preliminary Study.

It was mentioned in the former paper that the color of the ammonium

<sup>1</sup> Published by permission of the Director of the Bureau of Standards.

<sup>2</sup> The experimental work reported in this paper was carried out in 1912. Publication of the results has been delayed on account of the resignation of the authors since that time.

<sup>3</sup> "A Rapid Method for the Determination of Vanadium in Steels, Ores, etc., based on its Quantitative Inclusion by the Phosphomolybdate Precipitate." *Bur. Standards, Tech. Paper, 8.* J. R. Cain and J. C. Hostetter, *J. Ind. Eng. Chem.*, **4**, 250 (1912).

phosphomolybdate containing vanadium varies with the ratio of phosphomolybdate to vanadic acid (or, more conveniently expressed, of phosphorus to vanadium) at the time of precipitation. With small amounts of phosphorus and large amounts of vanadium the color of the resulting precipitate is deep orange or even dark red, while with greater quantities of phosphorus (with the same amount of vanadium) the precipitate approaches yellow as the limiting color. It was at first thought that this lighter color was due merely to a mixture of an ammonium vanado-phosphomolybdate with pure ammonium phosphomolybdate and, accordingly, experiments were made in order to determine which one of the numerous vanado-phosphomolybdates was present. This preliminary test consisted of a precipitation of the same quantities of phosphomolybdate in the presence of varied amounts of ammonium vanadate. If but one ammonium vanado-phosphomolybdate were formed under these conditions the precipitates formed from all solutions containing more than the required amount of vanadium would have the same color. Instead of possessing one color, however, the successive precipitates showed a progressive change from the very light orange of the one formed in the presence of little vanadium to the deep orange of that containing most vanadium. This made it evident that the resulting precipitate is not of constant composition, *i. e.*, it is not a chemical compound as the term is commonly used. Because of the indication afforded by this preliminary test it was decided to study the phenomenon quantitatively.

### 3. Quantitative Study.

#### A. Reagents.

The following solutions were prepared.

**Sodium Phosphate Solution.**—This was made up to contain about 124 g. of sodium phosphate,  $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$ , per liter of solution. It was standardized (1) by evaporating known volumes to dryness and igniting the residue to sodium pyrophosphate,  $\text{Na}_4\text{P}_2\text{O}_7$ , and (2) by precipitating as ammonium magnesium phosphate, and weighing finally as magnesium pyrophosphate,  $\text{Mg}_2\text{P}_2\text{O}_7$ . The value of 1 cc. of the solution was found to be by (1), 11.53 and by (2), 11.52 mg. of phosphorus.

**Ammonium Metavanadate Solution** was so prepared that 1 cc. was approximately equal to 0.5 mg. of vanadium. This solution was frequently standardized by titration with permanganate after reduction with hydrogen sulfide, sulfur dioxide, or hydrogen peroxide.<sup>4</sup>

**Potassium Permanganate Solution** was 0.01 *N*, and was standardized against sodium oxalate.

**Molybdate Reagent** was made up according to Blair.<sup>5</sup>

**Ammonium Molybdate Solution** contained 60 g. of the salt per liter.

<sup>4</sup> "The Reduction of Vanadic Acid in Concentrated Sulfuric Acid Solution by Hydrogen Peroxide and by Persulfates." J. R. Cain and J. C. Hostetter, *THIS JOURNAL*, 34, 274 (1912).

<sup>5</sup> Blair, "The Chemical Analysis of Iron," 8th ed., p. 92.

### B. The Ratio of Vanadium to Phosphorus in the Solid Phase.

**Series One. Vanadium Constant, Phosphorus Varied.**—A study of the ratio of phosphorus to vanadium in the solid phases, when constant amounts of vanadium and varied amounts of phosphorus are present, was carried out as follows. Equal volumes of the ammonium vanadate solution were measured into flasks; ammonium nitrate in definite amounts and sodium phosphate solution in gradually increased quantities were then added to the contents of the successive flasks. The different solutions were made up to equal volumes with water and then, after adjusting the temperature, the phosphorus was precipitated by molybdate reagent. The temperature of the phosphorus-vanadium solution could easily be adjusted so that after the addition of molybdate reagent the final temperature was approximately 65°. The phosphomolybdate was allowed to settle out and the amount of vanadium which was carried down was determined, as mentioned above, by reducing with hydrogen peroxide and titrating with permanganate. Other details are given in the tables.

		51.9	10.2		
		69.1	10.2		

After completing a series in this manner other series were run similarly but with different initial amounts of vanadium. The data so obtained are given in Table I, and shown graphically in Fig. 1.

Fig. 1.

Inspection of these curves shows that under the conditions that obtain here complete precipitation is brought about by an amount of phosphorus approximately 5 times that of the vanadium. This ratio of 5:1 is only half of that which was used in the investigation described in the first paper, but the larger excess was thought to be necessary in order to insure complete precipitation under the somewhat different conditions there employed. An excess of precipitant seems to eliminate irregularities in the amount of vanadium precipitated, which sometimes occur under different conditions of temperature, acidity and especially of agitation during the actual precipitation. Thus, shaking the precipitating solution on a mechanical shaker causes less co-precipitation of vanadium than when the reagents are merely mixed and the precipitate is allowed to form and settle. This, however, is true only when the amount of phosphorus is far too low for complete precipitation. Since, in the series that follow, the amount of phosphorus was always less than that required for complete precipitation, the precipitates were allowed to settle on standing rather than shaken out on a machine.

The curves of Series 1 follow, within the experimental error, the equation  $V/P = BC^m$ , in which  $V/P$  is the ratio of vanadium to phosphorus in the solid phase,  $C$  the concentration of vanadium remaining in the solution, and  $B$  and  $m$  are constants. Expressing  $C$  in mg. of vanadium in 100 cc. of solution, the equation is  $V/P = 0.38 C^{0.47}$ . Further discussion of these curves and of the above equation will be taken up later.

**Series Two. Phosphorus Constant, Vanadium Varied.**—In this series, equal amounts of phosphorus were precipitated in the presence of gradually increasing quantities of vanadium. The same conditions of precipitation obtain here as for Series One except that with the higher vana-

dium concentrations the flask was shaken until an actual separation of the solid phase took place, after which the rest of the precipitate separated on long standing.

The results obtained are given in Table II and shown in Fig. 2. A comparison of the curve with the curves of Series 1 shows that they are very similar in general character.

TABLE II.

PRECIPITATION OF VANADIUM. PHOSPHORUS CONSTANT; VANADIUM VARIED.

23.4 mg. of Phosphorus, 20 g. of Ammonium Nitrate, 50 cc. of Molybdate Reagent and Total Volume of 250 cc. in All Experiments. Room Temperature.

Total vanadium. Mg.	Vanadium pptd. Mg.
4.66	4.70
10.0	9.24
20.0	15.1
25.0	19.1
50.0	29.0
100	35.3
150	41.3
200	42.0

Closer study, however, reveals the fact that when the ratio of vanadium to phosphorus becomes very high the curve of Series 2 does not rise as

Fig. 2.

rapidly as would be expected. This is in accord with the well-known fact that ammonium phosphomolybdate is not precipitated at all in the presence of an exceedingly high concentration of vanadic acid. This unfortunate condition makes it impossible to extend the curve further, and hence limits the application of this method as applied to the preparation of ammonium vanado-phosphomolybdates.

It is essential to note that the color of the precipitates secured along this curve varies gradually from a light orange to a very dark orange.

This increase in color is continuous and is likewise parallel to the increasing vanadium content. Another interesting fact is that the color of the highest member of this series is very nearly that of the lowest member of a series of ammonium vanado-phosphomolybdates prepared in another manner by William Blum,<sup>6</sup> specimens of which he has very kindly placed at our disposal. In color, Blum's series ran through combinations

<sup>6</sup> Blum, *THIS JOURNAL*, 30, 1860 (1908).

of orange, red, and brown up to the highest member, which was black. Combining these two series we have then a perfect continuity in the colors possessed by the numerous ammonium vanado-phosphomolybdates. At one end of the complete series is ammonium phosphomolybdate with the ratio of vanadium to phosphorus equal to zero and at the other end ammonium phosphovanadate with this ratio relatively large. Extending from ammonium phosphomolybdate toward the other limiting compound there is probably a series of *solid solutions*, in which the relative quantities

Fig. 3.

of the components can vary continuously within certain limits. This point will be referred to later.

**The Co-precipitation of Arsenic with Ammonium Phosphomolybdate.**—For purposes of comparison we may here insert an account of an investigation by Frank and Hinrichsen<sup>7</sup> on the co-precipitation of arsenic with ammonium phosphomolybdate. The similarity between their results for arsenic and ours for vanadium is very striking. Their most complete series of experiments corresponds to that just described, namely, precipitation of arsenic with fixed concentration of phosphorus. Their results, plotted in Fig. 3, are quite comparable with those for vanadium plotted in Fig. 2. It is evident that the mechanism of the reaction in the case of arsenic is the same as that for vanadium.

**Series Three. Effect of Dilution.**—In this series the only condition that was varied was the concentration of the reacting substances at the time of precipitation. The total volume of the system was increased by steps from about 100 cc. to 1000 cc. The data are given in Table III and plotted in Fig. 4.

<sup>7</sup> Frank and Hinrichsen, *Stahl u. Eisen*, 28, 295 (1908).

TABLE III.

PRECIPITATION OF VANADIUM. EFFECT OF DILUTION AND OF AMMONIUM NITRATE CONCENTRATION.

Temp., 85°. 10.05 mg. of Vanadium, 23.04 mg. of Phosphorus, and 50 cc. of Molybdate. Reagents Used in All Experiments.

Ammonium nitrate. G.	Total volume. Cc.	Vanadium pptd. Mg.
5.0	108	9.24
	170	8.20
	200	6.42
	400	4.40
	600	3.09
	800	2.23
	1000	1.71
100.0	1000	8.94

*Effect of Ammonium Nitrate.*—In connection with the results obtained upon the effect of dilution on the amount of vanadium carried down it

Fig. 4.

was suspected that ammonium nitrate was an essential factor in the co-precipitation. Accordingly, the precipitation of the most highly diluted system (1000 cc. in volume) was repeated with the addition of 100 g. of solid ammonium nitrate. The result was, within the experimental error, identical with that obtained when the total volume was but 100 cc. This confirmed what had been empirically established before, that ammonium nitrate counteracts the influence of dilution on the co-precipitation of the vanadic acid. The theoretical significance of this will be discussed later.

An identical effect with ammonium nitrate was observed by Frank and Hinrichsen on the co-precipitation of arsenic by ammonium phosphomolybdate. In their experiments they used 20 or 30 g. of nitrate in 150 cc. and found that the co-precipitation of arsenic was favored by the addition of this salt.

**Series Four. Effect of Temperature.**—The results given in Table IV show that the maximum co-precipitation occurs within the range 40°–50°. The exact curve (Fig. 5) is difficult to reproduce but each set of

Fig. 5.

results exhibited a maximum in this region. These results are in partial accord with those of Brearley and Ibbotson<sup>8</sup> who found more vanadium precipitated at the higher than at the lower temperatures. These data are not in accord with their assertion, however, that phosphomolybdates precipitated in the cold are free from vanadium, a result that is possible only under limiting conditions, as is evident from the data already presented.

TABLE IV.

## PRECIPITATION OF VANADIUM. EFFECT OF TEMPERATURE.

10.05 mg. of Vanadium; 23.0 mg. of Phosphorus; 5 g. of Ammonium Nitrate; 50 cc. of Molybdate Reagent; Total Volume, 120 cc.

Temp. °C.	Vanadium pptd. Mg.
23	6.23
32	7.43
44	7.88
74	6.92
85	6.45

**Series Five. Effect of Acidity.**—The effect of acidity on the co-precipitation was studied by adding standardized nitric acid in gradually increased volumes to a succession of mixtures of otherwise neutral solutions of sodium phosphate, ammonium vanadate and nitrate. The precipitant was an ammonium molybdate solution prepared from the crystallized salt. The data given in Table V and presented graphically in Fig. 6

Fig. 6.

show that the maximum co-precipitation takes place in a nitric acid concentration of approximately 2 N. In practice this concentration is

TABLE V.  
EFFECT OF ACIDITY.

10.05 mg. of Vanadium; 23 mg. of Phosphorus; 2.5 g. of Molybdic Acid; 5 g. of Ammonium Nitrate; Total Volume, 170 cc. Temp., 65°.

roughly secured by adding to the nearly neutral solution, containing the vanadium and phosphorus, an equal volume of the molybdate reagent as ordinarily made.

#### 4. Discussion of Results.

A study of the curves in Series 1, 2 and 3 clearly indicates that (1) the curve showing the relation of phosphorus to vanadium in the solid phase is *logarithmic* and not linear as would be expected if the precipitate were a chemical compound; (2) with a given amount of phosphorus the amount of vanadium in the precipitate depends upon the *concentration of vanadium* initially present. The co-precipitation of the phosphorus and vanadium might be referred to as (1) an occlusion, (2) an absorption, (3) an adsorption, or (4) a partition effect. Without attempting to decide which term best describes the known facts, we shall merely call attention to the well-known fact that when any substance distributes itself between two solvents X and Y, the concentrations of the dissolved substance in the two solvents being  $C_x$  and  $C_y$  respectively and the molecular weight of the dissolved substance in the solvent X being 20 times the molecular weight in the solvent Y, then the ratio  $C_x/C_y^n$  is constant. Now, as shown above, the equation  $V/P = 0.38 C^{0.47}$  satisfactorily represents the curves of Series 1. In this equation  $C$  is the concentration of vanadium remaining in the solution, and if the precipitate be thought of as a *solid solution* of the vanadium compound in the phosphorus compound,  $V/P$  is for practical purposes the concentration of vanadium in the solid solution. That is,  $C_x/C_y^{0.47} = 0.38$ , and therefore the phenomena with which we are dealing may be described as a case of the distribution or partition of a solute (the vanadium compound) between two solvents one of which is a liquid and the other a solid. The exponent 0.47 is nearly equal to  $1/2$  and hence the molecular weight of the compound when dissolved in X (*i. e.*, in solid solution) would be half as great as its molecular weight in Y (*i. e.*, in aqueous solution). Whether or not this viewpoint is the correct one can be determined only by further experimentation, but for convenience we shall refer to the phenomena as a partition effect.

Inasmuch as we are dealing then with a partition effect it is evident that the precipitation of vanadic acid by ammonium phosphomolybdate is never complete. However, we can make the residual quantity just as small as we like by a process analogous to that of extraction with immiscible solvents. If the amount of vanadium is small we can secure all but the merest trace by making the quantity of precipitant sufficiently great. When the vanadium content is high, more thorough separation is obtained by precipitating several times with smaller portions of phosphomolybdate. If conditions are carefully adjusted and the ratio of phosphorus to vanadium is at least 10, only negligible traces of vanadium will remain in the solution when precipitating from 1 to 10 mg. of this element.

The effect of ammonium nitrate upon the partition—increasing the amount of vanadic acid carried down—may perhaps be a consequence of a repressing effect upon the dissociation of the vanadium complex co-precipitated. This would be in exact accord with what has been shown by Richards on the occlusion of ferric sulfate by barium sulfate;<sup>9</sup> by Richards, McClaffrey, and Bisbee, on the occlusion of magnesium oxalate by calcium oxalate;<sup>10</sup> and by Baxter on the occlusion of molybdic acid and ammonium molybdate by ammonium phosphomolybdate,<sup>11</sup>—namely, that co-precipitation in these cases is the distribution of an undissociated substance between the solution and the nascent solid. Any condition, therefore, which tends to decrease the concentration of the undissociated portion,—for instance, dilution,—tends to decrease the amount of this substance co-precipitated, and conversely.

**Vanado-phosphomolybdates in General.**—Taking up the subject of ammonium vanado-phosphomolybdates in general one cannot but wonder at the large number of these “compounds” that have been described. It is merely necessary to emphasize that no less than 27 of them are mentioned in Gmelin-Kraut<sup>12</sup> in addition to those (8 in number) subsequently prepared by Blum. We will note further that Toggenburg<sup>13</sup> found certain of his “compounds” underwent changes in composition when recrystallized.

It is difficult to believe that all of the combinations between these components that have been described are true chemical compounds. The large number of these “compounds” described in the literature is, in itself, a reason for considering them other than chemical compounds and suggests that they are related in some simple manner. That such a relation exists between the many members in this and in other series of salts of similar complex inorganic acids has already been suggested by Wherry.<sup>14</sup> From a study of the optical properties<sup>15</sup> of the series of vanado-phosphomolybdates prepared by Blum he concluded that “it is surely not permissible to call them chemical compounds,” and “that they are but a step removed from the so-called ‘adsorption-compounds’ of colloid-chemistry.” His conclusion is in harmony with the conclusions of this paper, since the relation between adsorption and occlusion is very close. That

<sup>13</sup> *Dissertation*, Bern, 1902, pp. 22 and 29.

<sup>14</sup> Wherry, *J. Franklin Inst.*, 169, 487 (1910).

<sup>15</sup> Some of the solids prepared in the course of this investigation were very kindly examined microscopically by Mr. A. A. Klein. Time was not available for the preparation of more suitable specimens, however, and accordingly the results obtained were not conclusive. The authors wish to express here their appreciation of Mr. Klein's interest in the matter.

these complex salts are indeed intimately related to "adsorption-compounds" is evident from the similarity between the equation representing the occlusion of vanadic acid and that of the "adsorption isotherm."

Having indicated, therefore, that many of the "ammonium vanado-phosphomolybdates" are probably solid solutions it is an easy task to account for their number. They may be considered as points on the curve showing the amount of vanadium occluded by a fixed amount of phosphorus in the presence of increasing amounts of vanadium. This curve is that of Series 2 and its extension. When viewed from this standpoint, one cannot but wonder that many more "compounds" have not been described, inasmuch as there is an infinite number of possible combinations.

The fact that Toggenburg found his salts to change composition on recrystallization is clearly accounted for by the partition effect already shown. It is, in fact, to be expected. If a solid separates from a solution of one of these salts it must bring about a partition of material between the solid and the solution, causing thereby a progressive change in composition of the solid. The composition of the solid phase would also depend upon the concentration of the solution (Series 3) and upon other conditions such as temperature (Series 4). Only under limiting conditions, therefore, would the solid phase be identical with that of the original salt.

### 5. Summary.

1. The co-precipitation of vanadic acid with ammonium phosphomolybdate may be explained as a phenomenon resulting from a partition of the vanadic acid in some undissociated form between the solution and the solid phase.

2. The maximum absorption by the solid phase occurs at a temperature of 40° to 50° and in a nitric acid concentration of 2 *N*.

3. The effect of dilution in lowering the amount of occlusion is a direct result of the partition law and can be minimized by the presence of ammonium nitrate, the latter probably tending to repress the dissociation of the vanadium complex which is occluded.

4. The ammonium vanado-phosphomolybdates are probably a series of solid solutions the end members of which may be ammonium phosphomolybdate and ammonium phosphovanadate; the exact relations can be established only by a thorough investigation of the appropriate systems.

Acknowledgment of helpful suggestions and criticism should here be made to Dr. William Blum of the Bureau of Standards and to Dr. L. H. Adams of the Geophysical Laboratory.

## THE POTENTIALS AT THE JUNCTIONS OF MONOVALENT CHLORIDE SOLUTIONS.

BY DUNCAN A. MACINNES AND YU LIANG YEH.

Received October 8, 1921.

### 1. Introductory.

The importance of the measurement and estimation of the potentials at the junctions of salt solutions does not need to be emphasized. Many investigations involving determinations of ion activities and of the free energies of reactions are rendered difficult or uncertain because of the necessity of correcting for these troublesome points of contact. The research to be described in the following pages was made with the purpose of finding the conditions for constant and reproducible junctions and with the hope of adding to our theoretical knowledge of the subject. The investigation was restricted to an examination of junctions of the type  $MCl | M'Cl$  in which  $M$  and  $M'$  represent hydrogen or one of the alkali metals. The same electrolyte concentration was maintained on both sides of each boundary. These junctions were studied because (a) electrodes reversible to the chloride ion are easily made and are reproducible, and (b) certain simplifying assumptions regarding the chloride ion have resulted from recent work. Further, as one of the authors has shown, connection between any two solutions of univalent ions, with one ion in common, can be made by combining a junction of the type just mentioned with one in which the concentration, but not the salt, changes. The formation and computation of the potentials of the latter type of junctions is now well understood.<sup>1</sup>

A large bibliography on liquid junctions could be collected, but the following references will be sufficient for our purpose. Apparently the first experimental work in connection with the evaluation of liquid junction was carried out by Nernst.<sup>2</sup> Further studies have been made by Lewis and Sargent,<sup>3</sup> by Cumming and Gilchrist,<sup>4</sup> by Meyers and Acree,<sup>5</sup> and by Lewis, Brighton and Sebastian.<sup>6</sup> In all but one of the articles mentioned the authors point out that the potentials of junctions connecting two different salts are variable. It seems to be tacitly assumed that the highest voltage, if moderately constant, is the "correct" value.

A method of renewing the surface between the two salt solutions, at intervals, is described by Lewis, Brighton, and Sebastian.<sup>6</sup> Walpole<sup>7</sup> has found that constant potentials can be obtained by forming the junctions with tapes, along which the solutions are flowed. The most decided advance, however, in the direction of the formation of reproducible potentials was made by Lamb and Larson<sup>8</sup> who used a device which produces a junction which is constantly renewed. The following investigation was made with an apparatus which in most respects resembles that of the authors just mentioned, although it was, to an extent at least, developed independently.

## 2. The Apparatus.

The apparatus used in our experiments on the more dilute solutions (0.01 *N*) is shown in Fig. 1.

The boundary which formed at A, resulted from the meeting of two slowly moving streams of solution from the reservoirs B and C. The flow was regulated by a screw pinchcock on a rubber tube attached to the tube F. An addition to the apparatus as described by Lamb and Larson is the glass rod D which is tipped with rubber. When lowered this rubber tip fits into a constriction in the tube and temporarily separates the two halves of the apparatus containing the different solutions, making it possible to fill the reservoir without mixing the liquids. Unless this device is used it is very difficult to sweep out the resulting mixed solutions in the apparatus and obtain constant potentials. The tubes between the electrodes G and H were, as far as possible,

Fig. 1.

made wide, so as to cut down the resistance and increase the sensitivity of the potential measurements. A similar apparatus but made of narrower tubing was used for the experiments with 0.1 *N* solutions.

In making a measurement the procedure was as follows. The apparatus was first dried and cleaned, then the rubber tip on D was pushed into the constriction near A, and the two solutions were poured into the appropriate portions of the vessel. The electrodes G and H and stoppers were next inserted, the pinchcock on F closed, the reservoirs B and C partly filled and the stopcocks closed. The whole apparatus was then placed in a thermostat where it was rigidly supported. Adjustment was then made so that the tops of the reservoirs B and C were accurately in the same horizontal plane, after which these reservoirs were completely filled. The system was then ready for lifting of the plug D, opening the stopcocks and the pinchcock on F, after which a boundary soon formed at A and measurements of the potential

<sup>7</sup> Walpole, *J. Chem. Soc.*, 105, 2521 (1914).

<sup>8</sup> Lamb and Larson, *THIS JOURNAL*, 42, 229 (1920).

between G and H were determined with the potentiometer. It is evident that if the precaution of leveling of the tops of the two reservoirs is not observed there will be an initial surge of liquid through the apparatus and mixing of the solutions at A will result. It was found that if such mixing occurred that no amount of flowing would produce constant potentials and that the experiment had to be started, with a dry vessel, from the beginning. It was also found that for a steady flow, and to avoid entrapping air, the stopcocks should be made of large bore, (about 2.5 mm.).

The nature of the boundary between the two solutions was made clearly visible by operating the apparatus with two solutions, one of which contained a few drops of phenolphthalein and the other a small amount of sodium hydroxide, the pink color of the indicator showing only at the surface of the solutions and in the region in which they had mixed or diffused. A surface of almost microscopic thinness started at A and persisted, with a slight thickening, throughout the length of tube F. If the flow is stopped the colored area thickens at A, if too rapid there is evidence of turbulence. The depression at A (also present in Lamb and Larson's apparatus) prevented mixing due to a "dead space."

### 3. The Reversible Electrodes.

Following Lewis and Sargent<sup>9</sup> some experiments were made with gold electrodes surrounded by the salt solutions under investigation, to which definite small amounts of ferro- and ferri-cyanides were added. Our experiments with these electrodes were, however, not successful. Calomel electrodes, although carefully made, were not very satisfactory, particularly with hydrochloric acid as electrolyte.

The final experiments were all carried out with silver-silver chloride electrodes formed on a platinum gauze, as described by MacInnes and Parker,<sup>10</sup> with the additional precaution, recommended by MacInnes and Beattie,<sup>1</sup> of forming the layer of chloride in a solution of the same concentration and composition as that in which the electrodes are to be used. Such electrodes agreed with each other, when placed in the same solution, to 0.03 mv. or less.

The electromotive-force measurements were made with a Leeds and Northrup potentiometer which was calibrated during the investigation. The standard cell used was compared at intervals with a cell which had been recently standardized by the Bureau of Standards. The apparatus was placed in a thermostat which was regulated to  $25^{\circ} \pm 0.03^{\circ}$ , the latter being measured on a thermometer calibrated by the Bureau mentioned.

### 4. Preparation of Solutions.

**Hydrochloric Acid.**—The hydrochloric acid solutions were prepared by diluting

<sup>9</sup> Ref. 3, p. 355.

<sup>10</sup> MacInnes and Parker, *THIS JOURNAL*, 37, 1445 (1915).

the constant-boiling mixture prepared as directed by Hulett.<sup>11</sup> The concentration of this acid was checked by analysis.

**Sodium and Potassium Chlorides.**—The "c. p." salts furnished by a well-known manufacturer were recrystallized 5 times from conductivity water and then fused. The solutions were then prepared by weighing out the requisite amount of dry salt.

**Ammonium Chloride.**—A good commercial grade of the salt was sublimed. A concentrated solution was then prepared and analyzed, after which solutions of desired concentrations were obtained by dilution.

**Lithium Chloride.**—This salt was kindly furnished, after careful purification, by J. A. Beattie of this laboratory. Solutions were made by diluting an analyzed concentrated solution.

**Cesium Chloride.**—Cesium chloro-iodide, which was prepared from an impure cesium salt, was recrystallized several times, after which the chloride was formed by heating. A 0.01 *N* solution was made by diluting an analyzed concentrated solution.

## 5. Theoretical Discussion.

A simple derivation, (similar in a number of respects to that given by Henderson,<sup>12</sup>) of an expression for the potential at a junction of the type  $\text{HCl}|\text{KCl}$ , in which the same concentration of electrolyte exists on both sides of the boundary, is given below. It differs from that of Planck in detail and in generality, but it has the advantage of indicating clearly the nature of the necessary assumptions, which can be compared with those of the more modern theory of strong electrolytes. For the sake of concreteness the derivation will be carried out with reference to solutions of the two substances given above.

At the surface where the two solutions meet there will be a layer in which the concentrations change continuously from pure hydrochloric acid to pure potassium chloride. Let us consider an intermediate plane in this layer. If the total concentration is  $c$  and that of the hydrochloric acid at all points in this plane is  $x$  then the concentration of potassium chloride is  $c - x$ . We are assuming that the boundary is formed by mixing and that appreciable diffusion has not occurred. Points on another plane a short distance,  $dl$ , away will have concentrations of  $x + dx$ , and  $c - (x + dx)$ , respectively. Let us consider the potential difference,  $dE_1$ , between two such planes. The passage of one faraday,  $F$ , of current across these planes will be attended by the change of free energy

$$FdE_1 = RT(T_K d\ln a_K + T_H d\ln a_H - T_{Cl} d\ln a_{Cl}) \quad (1)$$

in which  $E_1$  is the liquid junction potential,  $a_K$ ,  $a_H$  and  $a_{Cl}$  are the activities of the potassium, hydrogen and chloride ions and  $T_K$ ,  $T_H$  and  $T_{Cl}$  are the transference numbers of the ions in the mixture at this particular point. In this connection some recent work by Chow<sup>13</sup> and Harned<sup>14</sup> have shown that, for moderate concentrations, we can safely assume,

<sup>11</sup> Hulett, *THIS JOURNAL*, **31**, 390 (1902).

<sup>12</sup> Henderson, *Z. physik. Chem.*, **59**, 118 (1907).

<sup>13</sup> Chow, *THIS JOURNAL*, **42**, 497 (1920).

<sup>14</sup> Harned, *ibid.*, **42**, 1808 (1920).

for potassium chloride and hydrochloric acid solutions at least, that the activity of the chloride ion is the same in both solutions and throughout the boundary, *i. e.*, that  $d \ln a_{\text{Cl}} = 0$ .

The transference numbers  $T_{\text{K}}$  and  $T_{\text{H}}$  at points on the plane referred to above will be

$$T_{\text{H}} = \frac{x/c \cdot \Lambda_{\text{H}}}{x/c \cdot \Lambda_{\text{H}} + (c-x)/c \cdot \Lambda_{\text{K}} + \Lambda_{\text{Cl}}} \text{ and } T_{\text{K}} = \frac{(c-x)/c \cdot \Lambda_{\text{K}}}{x/c \cdot \Lambda_{\text{H}} + (c-x)/c \cdot \Lambda_{\text{K}} + \Lambda_{\text{Cl}}} \quad (2)$$

in which  $\Lambda_{\text{H}}$ ,  $\Lambda_{\text{K}}$  and  $\Lambda_{\text{Cl}}$  are the equivalent conductances of the ions at the concentrations involved. If  $x/c = l$  and  $\frac{c-x}{c} = (1-l)$  Equations 2 become

$$T_{\text{H}} = \frac{l\Lambda_{\text{H}}}{l\Lambda_{\text{H}} + (1-l)\Lambda_{\text{K}} + \Lambda_{\text{Cl}}} \text{ and } T_{\text{K}} = \frac{(1-l)\Lambda_{\text{K}}}{l\Lambda_{\text{H}} + (1-l)\Lambda_{\text{K}} + \Lambda_{\text{Cl}}} \quad (3)$$

The assumption that  $\Lambda_{\text{Cl}}$  is the same on both sides of the boundary is justified by the computations of Lewis<sup>15</sup> and of MacInnes,<sup>16</sup> except for solutions whose viscosities are appreciably different. Chow<sup>13</sup> and Harned<sup>14</sup> have shown that the individual activities of the ions of hydrochloric acid and potassium chloride are the same at one concentration in solutions of the pure substances and in mixtures of the same total electrolyte concentration. Under these conditions then the ratios of the ion activities  $a_{\text{H}}$  and  $a'_{\text{H}}$  at two planes in the junction will be proportional to the corresponding concentrations  $x$  and  $x'$ , and the activities of the other positive ion will be proportional to values of  $c-x$ . (This does not involve the assumption that the activities of the hydrogen and potassium ions are equal.) We, therefore, have the relations

$$d \ln a_{\text{H}} = d \ln x/c = d \ln l = dl/l \quad (4)$$

$$d \ln a_{\text{K}} = d \ln (c-x)/c = -d \ln (1-l) = -dl/(1-l). \quad (4a)$$

Substituting 3, 4, and 4a in 1:

$$F dE_1 = RT \frac{(\Lambda_{\text{H}} - \Lambda_{\text{K}}) dl}{l(\Lambda_{\text{H}} - \Lambda_{\text{K}}) + \Lambda_{\text{K}} + \Lambda_{\text{Cl}}}. \quad (5)$$

Integrating between  $l = 0$  and  $l = 1$  we have

$$E_1 = \frac{RT}{F} \ln \frac{\Lambda_{\text{K}} + \Lambda_{\text{Cl}}}{\Lambda_{\text{H}} + \Lambda_{\text{Cl}}}. \quad (6)$$

This equation, in which the conductances refer to the concentration under consideration rather than to the limiting values, is a modification of the original Planck equation recommended by Lewis and Sargent.<sup>3</sup>

To summarize, the assumptions involved in this derivation are: (a) that the electrolyte concentration is constant throughout the boundary, *i. e.*, that the boundary is formed by mixture and not by diffusion; (b)

<sup>15</sup> Lewis, *THIS JOURNAL*, **34**, 1640 (1912).

<sup>16</sup> MacInnes, *ibid.*, **41**, 1086 (1919), and **43**, 1217 (1921).

the ion activities are independent, at each concentration, of the nature of the (monovalent) oppositely charged ions in solution; and (c) the ion conductances are also independent, at each concentration, of the accompanying ions. The validity of (b) has been tested, as already mentioned, by Chow and by Harned, for solutions of the pure substances and for mixtures; assumption (c) at moderate concentrations holds for many, if not most of the univalent salts,<sup>17</sup> and is a close approximation for such mixtures as have been investigated. (Work on the conductances of mixtures of electrolytes is in progress in this laboratory.) Assumption (a) will be discussed in the next section.

It should also be noted that if the activity of the chloride ion at any one concentration is the same in two alkali chloride solutions or in hydrochloric acid the measured potential of a cell of the type,

is the potential of the liquid junction, since equal electrode potentials oppose each other.

## 6. Experiments on Rates of Flow.

With the apparatus described in the previous sections it was, of course, important to determine the effect of the rate of flow upon the potential

Fig. 2.

of the liquid junction. Fig. 2, in which the ordinates are potentials in millivolts and the abscissas times in minutes, summarizes, graphically, the results of the experiments on the junction between 0.1 *N* hydrochloric acid and 0.1 *N* potassium chloride. Curve I shows the effect of stopping the flow of a properly formed junction. The potential rises rapidly through a millivolt or more, and this is followed by a slow decrease of potential. It is the top of this curve that has, apparently, been considered to be the "correct" potential of the junction. At *b* on this curve the flow was started again and the original potential was quickly regained at *c*. At *d* the flow was again stopped and the potential rose to a different maximum, after which it slowly decreased. This time, at *e*, the original potential was almost instantly obtained from the higher value by starting the flowing. Curve II and III show the effect of too slow flowing, 1 and 2 drops a minute respectively dripping from the outlet tube. The

<sup>17</sup> See MacInnes, *This Journal*, 43, 1217 (1921).

dotted line represents the constant potential of the junction procured by the passage of from 3 to 7 drops a minute. Above the latter rate (from 8 drops per minute to rapid streaming) there was a perceptible decrease in the potential, but of the order of a few hundredths of a millivolt only. This was possibly due to drawing cool solutions from the reservoirs B and C into the boundary.

The phenomena underlying the curious rise of potential when the junction flow is stopped are obscure, but they are undoubtedly related to the fact that the moving junction tends to give a "mixture" boundary, *i. e.*, one in which the electrolyte concentration is constant throughout, whereas if time for diffusion is allowed there will be, immediately after stopping the flow at least, planes in the boundary at which the total concentration is greater than on either side, due to the fact that one electrolyte, in general, will have a greater diffusion constant than the other.

## 7. Experimental Results and Discussion.

The potentials at the junctions of solutions of hydrochloric acid with solutions of the alkali chlorides and of pairs of the alkali chlorides with each other, are given in Table I for 0.1 *N* solutions and in Table II for 0.01 *N* solutions. The different figures for each pair of electrolytes in the column headed "measured e. m. f." are the results of independent measurements, starting, in many cases, from freshly prepared solutions. The combination  $\text{HCl}|\text{KCl}$  at 0.1 *N* was, however, measured at least ten times with results that agreed within a few hundredths of a millivolt.

In the last column of each table the results of computations based on Lewis and Sargent's formula:  $E_1 = RT/F \cdot \ln \Delta_c/\Delta'_c$ , are given.<sup>18</sup> It is clear, on comparing this column of figures with that giving the directly measured values, that the Lewis and Sargent formula is remarkably successful in giving the order of magnitude of the liquid junction potential, but distinct variations are however to be observed. The junctions involving the potassium ion are, it will be noted, particularly far from agreement, the differences between the observed and computed values

<sup>18</sup> The following values for  $\Delta$  at 25° were used in this computation:

Substance.	0.01 <i>N</i> .	0.1 <i>N</i> .
HCl	411.6	390.4
KCl	141.4	129.0
NaCl	118.7	106.8
LiCl	108.6	96.7
NH <sub>4</sub> Cl	147.7	128.1
CsCl	144.6	...

Of these the values for the first three substances were taken from Noyes and Falk's compilation. (THIS JOURNAL, 34, 454 (1912)). The other values are computed from Kohlraush and Maltby's values at 18° and the temperature coefficients of Kohlraush and of Arrhenius, (Landolt and Börnstein, "Tabellen").

being close to 1.7 mv. at 0.1 *N* and 1.5 mv. for 0.01 *N* for each junction involving this ion. Since the mobilities of the potassium and ammonium ions are nearly equal the junction  $\text{KCl}|\text{NH}_4\text{Cl}$  would, according to any theory thus far advanced, be expected to be very low. The formula stated above gives 0.2 mv. for this junction whereas the measured potential is ten times that value. The difference between the observed and computed potentials is, however, nearly the same as that found for other combinations involving the potassium ion.

Since this abnormality of the potassium ion is very surprising, it was considered desirable, after the work described above was completed, to get independent measurements of some of the potentials of junctions involving that ion. With the aid of a liberal grant from the Warren Fund of the American Academy of Arts and Sciences, Mr. E. R. Smith of this laboratory repeated a number of the determinations. To be sure

that the abnormality was not due to the sample of potassium chloride used, measurements were made with (a) the material used in the foregoing experiments, (b) another sample of German origin, and (c) an American product. The latter two samples were purified as described in Section 4. The potentials of 0.1 *N* potassium chloride solutions against a newly prepared 0.1 *N* hydrochloric acid solution were as follows: Sample (a) 26.70 mv., Sample (b), 26.90 mv. and Sample (c), 26.87 mv. which agree substan-

tially with the value (26.78 mv.) given in Table I. Independent determinations were also made of the potentials of the junctions:  $\text{HCl}|\text{NaCl} = 33.11$  mv., and  $\text{KCl}|\text{NaCl} = 6.38$  mv. both at 0.1 *N*, and of the junction  $\text{HCl}|\text{KCl} = 25.74$  mv. at 0.01 *N*, all of which agree closely with the potentials given in the tables above. It would appear, therefore, that the deviation of the potentials of junctions involving the potassium ion from values predicted by the Lewis and Sargent formula are real and not due to experimental error or to impurities in the materials. This later work has also demonstrated that the apparatus, though apparently complex, will give correct results with but little practice in its use. Mr. Smith is now determining the potentials at the junctions of the alkali bromides. We wish, at this point, to express our gratitude to the Committee of the Warren Fund for its assistance.

The question immediately presents itself: Why do the potassium, and to a lesser extent the lithium, ions yield potentials that cannot be computed by the Lewis and Sargent formula, when junctions involving pairs of the hydrogen, sodium, cesium, and ammonium ions can be obtained from it almost within experimental error? We have at present no answer to offer, but we hope that the matter will be cleared up by further work.

There is, however, a remarkably simple relation connecting the observed potentials in Tables I and II. At both concentrations a figure can be obtained, for each electrolyte, such that the difference between any two figures gives the corresponding liquid junction potential. A set of such figures for each concentration can be found in Table III and the results of each subtraction are given in the columns headed "by difference" in Tables I and II. The figures in Table III are, of course, averaged from the results themselves. It will be seen that, with one exception, the potentials can be found, almost within experimental error, from these figures. This relation appears to be another instance of the remarkable additivity of the properties of solutions of strong electrolytes. As is obvious from the properties of the logarithm, a similar relation would hold if all the potentials could be calculated from Lewis and Sargent's equation or from Planck's original equation. The potassium and lithium ions behave, however, as if, in this connection, they have different  $\Lambda$  values than those obtained from conductance measurements.

### 7. Summary.

Using a slightly modified form of Lamb and Larson's "flowing" junction apparatus, reproducible values were obtained, within a few hundredths of a millivolt, of the potentials of the liquid junctions between equi-concentrated solutions of a series of monovalent chlorides. The Lewis and Sargent form of Planck's original equation,  $E_l = RT/F \ln \Delta c / \Delta' c$ , expresses the results for junctions involving most of the ions studied, and gives qualitative agreement in all cases. The experimentally determined potentials can, however, be obtained from the differences between numbers, one for each ion at each concentration. This is equivalent to the expression given above, except that, for the potassium and lithium ion, values of  $\Delta$  which are slightly different from those obtained from conductance measurements would have to be used.

CAMBRIDGE 39, MASSACHUSETTS.

### NOTES.

**A Simple Method for the Preparation of Sodium Hydroxide free from Carbon Dioxide.**—Having recently had occasion to prepare solutions of sodium hydroxide free from carbon dioxide, the method of preparation here described was evolved and in use found simpler than most methods commonly used.

**Method.**—Distilled water contained in an Erlenmeyer flask is boiled to remove any carbon dioxide present, after which, when the water is cooled enough, ethyl ether is added to form a layer 3 or 4 cm. in depth. Pieces of metallic sodium, not exceeding about 1 cm. in diameter are then dropped into the flask. They will fall no further than the ether layer where they remain suspended. The water contained in the ether layer causes the slow formation of sodium hydroxide, which readily passes below to the water layer. Meanwhile the ether prevents the results usually observed when metallic sodium is brought in contact with water in the presence of air. After the desired quantity of metallic sodium has reacted, the larger portion of ether is removed by a pipet, and the last traces by boiling the solution. Various modifications and adaptations will suggest themselves to the reader.

**Fire Hazard.**—It would seem that the above procedure is fraught with considerable danger from fire and explosions. Particular effort was made to cause explosions. As a result it was observed that none occurs so long as the depth of the ether layer is great enough so that the suspended sodium cannot simultaneously come in contact with both air and water. When the quantity of sodium to be dissolved is rather large in proportion to the quantity of ether present it sometimes happens that the heat evolved by the reaction is sufficient to evaporate the ether sufficiently to cause

fire hazard. Obviously, this condition is easily corrected by the addition of more ether to the flask. Of the explosions resulting by intentionally adding large quantities of sodium to a shallow ether layer, none was of sufficient violence to break the containing flask which, of course, was unstoppered. With the care ordinarily exercised in handling ether and by keeping the ether layer as thick as 3 or 4 times the diameter of the largest piece of sodium being dissolved, the reaction is carried out easily and without danger. A further advantage of the method arises from the fact that the greater part of any kerosene adhering to the sodium is removed with the ether.

**Purity of Product.**—No precipitate is formed when a solution of barium hydroxide is added to a solution of sodium hydroxide prepared by this method; but further than this, no critical examination has been made to learn whether or not this product is of sufficient purity for purposes requiring high precision. It is hoped to extend the work to include a study of the applicability of this method to the preparation of the hydroxides of all the alkalis and alkali earth metals and to a critical examination of the purity of the resulting products.

**The Nesslerization of Ammonia Solutions.**—In using the Folin-Bell<sup>1</sup> method for the determination of ammonia in urine and the Folin-Youngburg<sup>2</sup> method for the determination of urea in urine, we found trouble in keeping the product of the nesslerizations dissolved. This uncertainty concerning clouds and precipitates forming in nesslerized mixtures had been mentioned by Allen and Davisson<sup>3</sup> in a paper on colorimetric work. We set out to find what were the necessary conditions for a successful nesslerization that would give a solution yielding no precipitate on standing for the usual time required for the colorimetric determination.

We have found several precautions necessary. When any of these are not carefully observed the product of the nesslerization will be partly dissolved and partly precipitated. If the following precautions are taken the product of the nesslerization will be a clear sparkling solution with no visible precipitate.

1. All dilutions must be made with distilled water. Tap water, even though ammonia-free, has not been found advisable.

2. The flasks in which the nesslerizations are made should be well rinsed with c. p. nitric acid and then with distilled water to remove the mercury film that may have separated from a previous nesslerization.

<sup>1</sup> Folin and Bell, *J. Biol. Chem.*, 29, 333 (1917).

<sup>2</sup> Folin and Youngburg, *ibid.*, 38, 111 (1919).

<sup>3</sup> Allen and Davisson, *ibid.*, 40, 196 (1919).

3. The Nessler solution used should be the one recommended by Folin in his later paper.<sup>4</sup> Folin's earlier Nessler solution<sup>5</sup> was not found to work as well.

4. The given amount of Nessler solution (10 cc. to 20 cc.) must be added rapidly all at once. We found that a wide-mouthed pipet or cylinder worked very well. Slow addition of the reagent was not good.

5. After the addition of the Nessler solution, the mixture must not be shaken or stirred. It must be left perfectly quiet for at least 20 minutes. When the reagent is added, the solutions mix instantly as intimately as is possible with shaking. Any dilution with water to a definite volume must be done gently and only after the 20 minutes' standing period.

6. The solution to be nesslerized should not contain over 1.0 mg. of ammonia nitrogen for 150 cc. of solution. On nesslerization and dilution of the product to 200 cc., the brown color is very intense, and with such concentrated solutions part of the product tends to deposit on the walls of the flask and interfere with the colorimetric work.

After determining the necessary precautions we tried some 200 nesslerizations, leaving out some one or another of the above precautions. Only very rarely were we able to obtain successful results. Using the precautions mentioned, in more than 200 nesslerizations, we did not meet with a single failure. We therefore believe that the method outlined above affords complete control and gives solutions that are clear and remain so for hours. The necessary precautions are not bothersome.

**The Preparation of Chloroplatinic Acid by Means of Hydrogen Peroxide.**—Since the use of concentrated hydrogen peroxide and hydrochloric acid instead of aqua regia for solution of platinum black in the preparation of chloroplatinic acid was first described,<sup>1</sup> the technique has been improved in several details, and it seems worth while at this time to describe briefly the method developed after several years of experience.

The presence of organic compounds, other than sodium formate, was avoided from the start and for this reason the difficulty with acetanilid

<sup>4</sup> Folin and Wu, *J. Biol. Chem.*, **38**, 89 (1919).

<sup>5</sup> Folin, *ibid.*, **26**, 473 (1916).

<sup>1</sup> Rudnick and Cooke, *THIS JOURNAL*, **39**, 633 (1917).

mentioned by Braley and Shaffer in their paper<sup>2</sup> was never encountered. The peroxide used in this work was, from the very first concentrated from a commercial product stated to be free from acetanilid, alcohol, etc.

Platinum black seems to dissolve more readily if it is not allowed to become dry after reduction. In order to combine this advantage with the necessity of keeping account of yields and of the amount of platinum in stock, the purified potassium chloroplatinate rather than the dried platinum black was chosen as the starting point for the preparation of the final solution. This offers the further advantage of starting with a pure compound for reduction and so obtaining a clean, quick and perfect separation of the platinum black.

Another important point developed was the use of hydrogen chloride instead of the strong aqueous acid. Hydrogen chloride is so easily made by the usual method of adding conc. sulfuric acid to conc. hydrochloric acid that this point offers no difficulty to offset the advantage of concentration and increased speed of solution.

The method, then, as at present used may be briefly described as follows.

The potassium chloroplatinate residues accumulating from the determinations of potash are extracted with the smallest possible quantities of boiling water and filtered while hot so as to separate all asbestos and paper fibers of the filter pads. The pure chloroplatinate crystals obtained on cooling are dried and form a part of the material for preparation of the reagent.

The filtrate and all other aqueous filtrates, including the spent Lindo-Gladding solution, are reduced with zinc and hydrochloric acid. All filtrates from this reduction are allowed to stand exposed to sunlight as much as possible for several weeks. Sometimes additional platinum black is obtained in this way.

The alcoholic filtrates are evaporated until the alcohol is driven off as judged by the odor. The residue is then reduced with zinc and hydrochloric acid and further treated in the same manner as the aqueous filtrates referred to in the preceding paragraph.

Whenever platinum black comes down in the form of a mirror, or otherwise does not lend itself readily to solution with hydrogen peroxide in a small volume, it is best to dissolve such deposits with a little nitro-hydrochloric acid. The nitric acid is evaporated and the remaining solution is added to the next lot of filtrate to be reduced with zinc and hydrochloric acid.

The more or less granular crude platinum black thus obtained is thoroughly washed by decantation and is then treated with hydrogen chloride.

<sup>2</sup> The Interaction of Platinum, Hydrochloric Acid and Hydrogen Peroxide. Presented at the April, 1921, Meeting of the American Chemical Society, Rochester, N. Y.

To this in suspension conc. hydrogen peroxide<sup>3</sup> is added and hydrogen chloride is bubbled through simultaneously in such manner that the bubbles keep the platinum black well agitated. After the flow of gas and of peroxide have been properly regulated, the process needs very little attention and solution is complete in the course of some hours, the time depending on the amount of platinum black to be dissolved.

The solution thus obtained is treated with the necessary amount of pure potassium chloride and the potassium chloroplatinate crystals are filtered off, dried and added to the stock of pure chloroplatinate on hand.

From a weighed amount of this stock the reagent is prepared by reduction with alkaline sodium formate, washing the platinum black obtained and dissolving it as described above. This solution is then made up to the proper volume as calculated from the weight of chloroplatinate taken, so that 10 cc. of the reagent contains 1 g. of metallic platinum, as required by the official methods of the A.O.A.C.<sup>4</sup>

**FRIEDEL AND CRAFTS' REACTION. SOME SUBSTITUTED  
PHTHALIC ANHYDRIDES WITH TOLUENE AND  
ALUMINUM CHLORIDE.**

BY WALTER A. LAWRENCE.  
Received June 18, 1921.

As pointed out in a previous paper<sup>1</sup> an unsymmetrical phthalic anhydride with benzene and aluminum chloride may give two acid products. In some of the reactions described in this paper two acid products were obtained, in others only one. With the symmetrical tetrahalogenophthalic anhydrides only one acid product was obtained as was to be expected.

The physical properties of the toluyl-nitrobenzoic acids are very similar

<sup>3</sup> The conc. hydrogen peroxide should be freshly prepared immediately before use. Commercial peroxide, free from preservatives, is concentrated by distillation at reduced pressure to  $\frac{1}{10}$  its volume. The reservoir of commercial peroxide is connected to a Pyrex distilling flask, holding about twice the volume of conc. peroxide to be prepared, and the initial volume in the flask, which is the final volume desired, is maintained. The distillation is carried on under a pressure of 50 mm. of mercury or less and the bath is kept at a temperature 5° to 10° higher than the boiling point of water at the pressure in the flask.

Hydrogen chloride is prepared in the usual manner by adding conc. sulfuric acid to conc. hydrochloric acid in a suitable generator.

<sup>4</sup> Official Methods, A.O.A.C., 1920, p. 12.

<sup>1</sup> Lawrence, *THIS JOURNAL*, 42, 1871 (1920).

to those of the benzoyl-nitrobenzoic acids. They are brownish amorphous powders which do not have a sharp melting point and decompose on melting and while somewhat more soluble in hot than in cold alcohols, they do not crystallize from these solvents.

In all the acids obtained the toluene is represented as entering the reaction at the position *para* to the methyl group. The sodium, potassium and ammonium salts of all the toluyl-tetrahalogeno-benzoic acids are only slightly soluble in water. A small quantity of each of the benzoyl-tetrahalogeno-benzoic acids described by Alice Hofmann<sup>2</sup> was prepared and it was found that their alkali salts are also only slightly soluble in cold water.

**General Procedure.**—The derivative of the phthalic anhydride was treated with aluminum chloride and excess of toluene in the proportion of two mol. wts. of aluminum chloride to one mol. wt. of the anhydride. In most of the experiments about 9 g. of aluminum chloride was used and 45 to 50 cc. of toluene. After heating until hydrogen chloride ceased to come off, 10% hydrochloric acid was added, the contents of the flask were shaken and the excess of toluene distilled with steam. The residue was filtered, washed and boiled with a saturated solution of sodium carbonate. The alkaline solution was filtered and the filtrate acidified slowly with 10% hydrochloric acid.

**3-Nitrophthalic Anhydride with Toluene and Aluminum Chloride.**—The yield was 51%, calculated on the anhydride. The two isomeric acids in this precipitate have no marked solubility differences, but a somewhat unsatisfactory separation was effected by methyl alcohol.

**Identification of the Acid Less Soluble in Methyl Alcohol.**—This acid is very soluble in acetone, moderately soluble in ethyl alcohol, less soluble in methyl alcohol and almost insoluble in ether and ligroin; m. p. 262–5° (decomp.).

**Hydrolysis.**—A solution of 2 g. of the acid and 10 g. of potassium hydroxide was heated in a nickel crucible to about 215° for 20 minutes. When cold the mass was dissolved in water, filtered, acidified and the precipitate dried. When heated for several hours on the water-bath the sublimate was *p*-toluic acid and the residue was *o*-nitrobenzoic acid.

**Synthesis.**—Nine g. of 2-carbethoxy-3-nitrobenzoyl chloride<sup>3</sup> was dissolved in 45 cc. of toluene and 9.5 g. of powdered aluminum chloride slowly added. The mixture became warm and large quantities of hydrogen chloride were given off. When the initial reaction was over the mixture was heated on the water-bath for 8 to 9 hours, acidified and the excess of toluene removed. The product, a tarry viscous oil, was hydrolyzed with alcoholic potassium hydroxide, the potassium salt dissolved in water and the solution acidified. The acid was purified by dissolving in hot alcohol and allowing the solution to cool, when a light brown amorphous powder was obtained which melted

<sup>2</sup> Hofmann, *Monatsh.*, 36, 805 (1915).

<sup>3</sup> In my previous paper it was stated that the carbethoxy-nitrobenzoyl chlorides from 3-nitrophthalic acid had not previously been described. Since publication I have found that they had been described by Cohen, Woodroffe and Anderson, *J. Chem. Soc.*, 109, 234 (1916).

with decomposition at 262-5°; yield about 53%. This product, therefore, is 6-*p*-toluyl-2-nitro-benzoic acid.

*Analysis.*—Calc. for  $C_{15}H_{11}O_5N$ : N, 4.91. Found: 4.72.

*Identification of the Acid More Soluble in Methyl Alcohol.*—From a hot saturated solution of the acid in methyl alcohol a small quantity of a light brown amorphous powder was obtained which darkened at 105-7° and decomposed at 122-6°.

*Hydrolysis.*—Fusion with potassium hydroxide gave two products which were separated by sublimation. They were identified as *p*-toluic acid and *m*-nitrobenzoic acid.

*Synthesis.*—Nine g. of 6-carbethoxy-2-nitrobenzoyl chloride was dissolved in 45 cc. of toluene and 9.5 g. of aluminum chloride added slowly. The reaction began in the cold and no heat was applied for one hour. The mixture was then heated on the water-bath for 9 hours, cooled, acidified and the toluene distilled. The viscous, black, oily ester was hydrolyzed with 8% alcoholic potassium hydroxide. The acid so prepared darkened at 106-9° and decomposed at 123-6°. This product is, therefore, 2-*p*-toluyl-3-nitrobenzoic acid.

*Analysis.* Calc. for  $C_{15}H_{11}O_5N$ : N, 4.91. Found: 4.71.

**4-Nitrophthalic Anhydride with Toluene and Aluminum Chloride.**—The precipitate obtained by acidifying the sodium carbonate solution was found to consist almost altogether of an acid soluble in ethyl alcohol and melting with decomposition at 100-105° but there was a small quantity of material less soluble in ethyl alcohol melting with decomposition at 211-18°.

*Identification of the Acid Melting with Decomposition at 100-105°.*—This acid is soluble in methyl alcohol, ethyl alcohol and acetone, slightly soluble in ether and benzene and insoluble in ligroin.

*Hydrolysis.*—Fusion with potassium hydroxide for 20-25 minutes at 210-20° gave *p*-toluic acid and *p*-nitrobenzoic acid.

*Synthesis.*—Ten g. of 6-carbo-methoxy-3-nitrobenzoyl chloride was dissolved in 50 cc. of toluene and 9 g. of powdered aluminum chloride slowly added. The reaction began vigorously in the cold, and after standing for one hour the mixture was heated on the water-bath for 6-7 hours. The black viscous product obtained after acidification and removal of the toluene was hydrolyzed with 8% alcoholic potassium hydroxide redissolved in sodium carbonate solution, precipitated by acid, washed and dried; m. p. 101-5° with decomposition; yield, 55%.

This acid is, therefore, 2-*p*-toluyl-4-nitrobenzoic acid.

*Analysis.* Calc. for  $C_{15}H_{11}O_5N$ : N, 4.91. Found: 4.77.

**3-Acetyl-amino-phthalic Anhydride with Toluene and Aluminum Chloride.**—The solution obtained by using cold sodium carbonate on acidification gave an acid which on purification melted at 256-7°. The residue from the sodium carbonate solution after washing with cold benzene gave an acid which on further purification melted at 206°.

*Partial Identification of the Acid Melting at 256-7°.*—This acid is not very soluble in water but small quantities of very pure crystals may be obtained by making a saturated solution in hot water, allowing the solution to cool, and repeating this once or twice. It is soluble in ethyl and methyl alcohol. Yield about 20%, calculated on the anhydride.

*Hydrolysis.*—When fused with potassium hydroxide for 20 minutes at 200-215° and acidified only *p*-toluic acid and benzoic acid were recognized. This indicates that the aminobenzoic acid was converted into benzoic acid during the fusion.

Reduction of the *p*-toluyl-nitrobenzoic acids by ferrous sulfate and also by zinc and acetic acid was attempted, but the results were unsatisfactory, due in part to the limited amount of pure acids available.

This acid is, therefore, 2- or 6-*p*-toluyl-3- or 2-aminobenzoic acid.

*Analysis.* Calc. for  $C_{15}H_{12}O_3Na$ : Ag, 29.8. Found: 30.0.

*Partial Identification of the Acid Melting at 206°.*—This acid is not very soluble in cold sodium carbonate solution but is somewhat soluble in the hot solution. The alkaline solution was acidified and the precipitate dried; yield about 40% calculated on the anhydride used. It was recrystallized twice from ethyl alcohol. It is soluble in acetone, slightly soluble in ether and insoluble in benzene.

*Hydrolysis.*—Fusion with potassium hydroxide at 210–20° for 20 minutes gave a product from which *p*-toluic acid and a small amount of benzoic acid were obtained.

This acid is, therefore, 2- or 6-*p*-toluyl-3- or 2-aminobenzoic acid.

*Analysis.* Calc. for  $C_{15}H_{12}O_3Na$ : Ag, 29.8. Found: 29.65.

**4-Acetyl-amino-phthalic Anhydride with Toluene and Aluminum Chloride.**—The precipitate consists principally of one acid; only a small quantity of the second acid was found; yield, 62%.

*Partial Identification of the Acid Melting at 135–6°.*—The precipitate from the carbonate solution was dissolved in alcohol and water added until a faint cloudiness appeared. On standing for several hours a small quantity of gum separated; the alcohol which still contained the bulk of the material was poured off and allowed to slowly evaporate at room temperature. The second deposit was still gummy but on drying was easily powdered. Repeating this operation gave a product melting at 135–6°. It is soluble in ethyl alcohol, methyl alcohol and acetone, slightly soluble in benzene and insoluble in ether.

*Hydrolysis.*—Fusion with potassium hydroxide at 205–215° for 25 minutes gave a product from which *p*-toluic acid and a small quantity of benzoic acid were obtained.

This acid is, therefore, 2- or 6-*p*-toluyl-4- or 3-aminobenzoic acid.

*Analysis.* Calc. for  $C_{15}H_{12}O_3Na$ : Ag, 29.8. Found: 29.7.

The small quantity of material which separated first from the alcohol solution was dried *in vacuo*, dissolved in sodium carbonate solution, precipitated with acid, washed and dried; m. p. 180–3°. It is soluble in acetone and almost insoluble in benzene or ether. It is probably the isomeric acid, but sufficient quantity for identification was not obtained.

**Tetrachloro-phthalic Anhydride with Toluene and Aluminum Chloride.**—The dried product weighed 12.4 g. corresponding to a 94% yield. When recrystallized from alcohol it melted at 174.5° corr. This acid is soluble in alcohol, ether or acetone. It may be recrystallized from benzene. The sodium, potassium and ammonium salts are only slightly soluble in water.

*Hydrolysis.*—Fusion with potassium hydroxide at 210–5° for 15 minutes gave a product from which *p*-toluic acid and a small quantity of 2,3,4,5-tetrachloro-benzoic acid were obtained.

It is, therefore, 6-*p*-toluyl-2,3,4,5-tetrachloro-benzoic acid.<sup>4</sup>

*Analysis.* Calc. for  $C_{18}H_8O_3Cl_4$ : Cl, 37.5. Found: 37.1.

*Methyl Ester.*—Five g. of the acid was boiled for 50 minutes with 50 cc. of methyl alcohol and hydrogen chloride. On cooling to 10° most of the ester crystallized out. On recrystallization from methyl alcohol the ester was colorless, m. p. 96–97° (corr.). It is soluble in ethyl alcohol and acetone and slightly soluble in ether and benzene.

**Tetrabromo-phthalic Anhydride with Toluene and Aluminum Chloride.**—The dried product weighed 10.7 g. which represents an 89% yield. When recrystallized from methyl alcohol the acid melts at 212° (corr.). It may also be recrystallized from

<sup>4</sup>Brit. pat. 8917 (April 8, 1914) mentions this acid.

benzene or chloroform. It is soluble in acetone but insoluble in ether or water. The sodium, potassium and ammonium salts are only slightly soluble in water.

*Hydrolysis.*—Fusion with potassium hydroxide at 210–220° for 20 minutes gave a product from which *p*-toluic acid was isolated.

This compound is, therefore, 6-*p*-toluyl-2,3,4,5-tetrabromo-benzoic acid.

*Analysis.* Calc. for  $C_{15}H_9O_3Br_4$ : Br, 57.5. Found: 56.8.

*Methyl Ester.*—Five g. of the acid was dissolved in warm methyl alcohol containing hydrogen chloride and boiled for one hour. Most of the alcohol was then distilled off and the remainder poured into water. It was recrystallized from methyl alcohol, m. p. 162.5 (corr.). It is soluble in ethyl alcohol, benzene, ethyl acetate and ether.

*Tetra-iodo-phthalic Anhydride with Toluene and Aluminum Chloride.*—The dried product weighed 10.2 g., a 91% yield. When recrystallized from methyl alcohol or benzene it was pale yellow and melted at 266° (corr.). It is soluble in acetone and slightly soluble in water, ether and chloroform. Its sodium, potassium and ammonium salts are only slightly soluble in water.

*Hydrolysis.*—Fusion with potassium hydroxide at 200–215° for 30 minutes gave *p*-toluic acid and the acid is, therefore, 6-*p*-toluyl-2,3,4,5-tetra-iodo-benzoic acid.

*Analysis.* Calc. for  $C_{15}H_9O_3I_4$ : I, 68.25. Found: 67.9.

*Methyl Ester.*—Five g. of the acid was boiled for 1 hour with 50 cc. of methyl alcohol and hydrogen chloride and  $\frac{1}{2}$  of the alcohol was then distilled and the remainder poured into water. The ester when recrystallized from methyl alcohol was pale yellow and melted at 199° (corr.). It is soluble in alcohol, benzene and ethyl acetate and slightly soluble in ether.

### Summary.

1. The reaction of aluminum chloride and toluene with each of 7 derivatives of phthalic anhydride has been investigated.

2. Eleven new compounds have been prepared: 6-*p*-toluyl-2-nitro-benzoic acid, 262–5° (decomp.); 2-*p*-toluyl-3-nitrobenzoic acid, 123–6° (decomp.); 2-*p*-toluyl-4-nitrobenzoic acid, 101–5° (decomp.); 2- or 6-*p*-toluyl-3- or 2-aminobenzoic acid, 256–7°; 2- or 6-*p*-toluyl-3- or 2-amino-benzoic acid, 206°; 2- or 6-*p*-toluyl-4- or 3-aminobenzoic acid, 136–7°; methyl 6-*p*-toluyl-2,3,4,5-tetrachloro-benzoate, 96–7°; 6-*p*-toluyl-2,3,4,5-tetrabromo-benzoic acid, 212°; methyl 6-*p*-toluyl-2,3,4,5-tetrabromo-benzoate, 162.5°; 6-*p*-toluyl-2,3,4,5-tetra-iodo-benzoic acid, 266°; methyl 6-*p*-toluyl-2,3,4,5-tetra-iodo-benzoate, 199°.

3. The properties of 6-*p*-toluyl-2,3,4,5-tetrachloro-benzoic acid have been described.

This research was done under the direction of Professor F. B. Allan.

## HYDROXY-NAPHTHOQUINONE STUDIES. IV. NEW DERIVATIVES OF 2,3,8-TRIBROMO-5-HYDROXY-1,4-NAPHTHOQUINONE.<sup>1</sup>

BY ALVIN S. WHEELER AND T. M. ANDREWS.

Received July 22, 1921.

The papers<sup>2</sup> preceding this one dealt with (1) the reduction of naphthazarine to tetrahydroxy-naphthalene which presented a case of tautomerism of the keto-enol type; (2) the bromination of naphthazarine which revealed a case of isomerism not yet explained; (3) the chlorination and bromination of juglone or 5-hydroxy-1,4-naphthoquinone. The present investigation has extended the field which was opened up by the halogenation of juglone. It is a surprising thing that the bromination of juglone in hot glacial acetic acid solution gives a tribromo derivative in nearly quantitative yield whereas chlorination gives under similar conditions a dichloro derivative. By over-dosing the juglone with chlorine the yield is reduced and the more soluble product contains a higher percentage of chlorine but not sufficient for a trichloro-juglone. Up to the present we have been unable to prepare such a compound.

The present work more thoroughly confirms our belief that the third bromine atom is in the phenol ring, *para* to the hydroxyl group. Tribromo-juglone is a stable compound, so that there is no likelihood that two bromine atoms are attached to one carbon atom *ortho* to another carbon to which a bromine atom is joined, *i. e.*, a 2,2,3-tribromo-juglone. One bromine atom is much more reactive than the other two; hence we place it in Position 8, *para* to the hydroxyl group. All of the reactions but one in this study leave the two other bromine atoms unaffected.

The new tetrahydroxy-naphthalene (C in Fig. 1) is the simplest of the new compounds which came to light in this research. Only two of the many possible isomers have been described; (1) the 1,2,5,8-isomer described by Zincke and Schmidt<sup>3</sup> or the 1,4,5,6 as one<sup>4</sup> of us prefers to call it and (2) the 1,2,5,8-isomer of Zincke and Ossenbeck.<sup>5</sup> The new one is the 1,4,5,8-isomer. It resembles the second in its instability and was not obtained in a pure condition. It was prepared by the reduction of the dihydroxy-dibromo-naphthoquinone (B) with zinc in alkaline solu-

<sup>1</sup> This paper constitutes a portion of a thesis submitted by T. M. Andrews to the Faculty of the Graduate School of the University of North Carolina in partial fulfillment of the requirements for the degree of Doctor of Philosophy.

(N, O, P, Q) but *p*-nitro-aniline gave a derivative whose character we have not yet determined.

We wish to thank the National Aniline and Chemical Company of Buffalo for a supply of 1,5-dihydroxy-naphthalene which greatly aided us in this work, saving us much time in preparing this compound from naphthalene. We oxidized the dihydroxy-naphthalene to juglone in the usual way with dilute chromic acid solution. The bromination of juglone was carried out by the very smoothly working method of Wheeler and Scott.<sup>6</sup>

### Experimental Part.

**1,4,5,8-Tetrahydroxy-naphthalene (C).**  $C_{10}(OH)_4$ .—Although the bromine atoms in tribromo-juglone resist the action of acid reducing agents, they are readily affected in alkaline solution. If zinc and sodium hydroxide are employed bromine atoms 2 and 3 are replaced by hydrogen, the one at 8 by an hydroxyl group and the quinone oxygens are reduced to hydroxyl groups. One g. of tribromo-juglone is dissolved in alcohol, 40 cc. of 5% sodium hydroxide is added and the mixture heated 1 hour. This process substitutes an hydroxyl group for Bromine 8. The solution is acidified with dil. sulfuric acid, the precipitate is filtered off and washed with water. It is then added to a 30% solution of sodium hydroxide which is kept hot on a steam-bath. Zinc dust is added from time to time for 3 hours. The solution finally becomes nearly colorless except for the surface, which remains reddish. The hot solution is acidified with dil. sulfuric acid, cooled and extracted with ether. The product crystallizes from ether in plates of a light gray color. The purest product obtained melted at 224°.

*Analyses.* Subs., 0.2500:  $CO_2$ , 0.6092, 0.5926;  $H_2O$ , 0.1170, 0.1173. Calc. for  $C_{10}H_8O_4$ : C, 62.50; H, 4.16. Found: C, 64.65; H, 5.21.

**1,4,5,8-Tetrahydroxy-2,3-dibromo-naphthalene (D).**  $C_{10}H_2Br_2(OH)_4$ .—The reduction of dihydroxy-dibromo-juglone (H) was carried out by dissolving 2 g. in ether, adding dil. sulfuric acid and small portions of zinc dust from time to time, shaking well. In a few minutes the solution becomes nearly colorless. The ether layer is separated, washed with water and evaporated. The residue is pale green in color, weighs 1.8 g. and melts at 149–153°. Purification is effected by crystallizing from chloroform. The pure substance melts at 164–166° with decomposition and consists of long colorless needles which are very soluble in ether, alcohol and glacial acetic acid.

*Analyses.* Subs., 0.2210, 0.1893: AgBr, 0.2361, 0.2010. Calc. for  $C_{10}H_6O_4Br_2$ : Br, 45.71. Found: 45.48, 45.21.

**1,4,5,8-Tetra-acetoxy-2,3-dibromo-naphthalene (E).**  $C_{10}H_2Br_2(OCOCH_3)_4$ .—Two g. of the tetrahydroxy compound was boiled in 20 cc. of glacial acetic acid for 20 hours. On cooling a gummy yellowish mass separated, but it crystallized in a short time. The product weighed 2.4 g. and melted below 143°. By recrystallization of the compound several times from glacial acetic acid the melting point was raised to 149–150°. The crystals were short colorless needles. They were only slightly soluble in ether, alcohol and chloroform.

*Analyses.* Subs., 0.2174, 0.1778: AgBr, 0.1557, 0.1294. Calc. for  $C_{18}H_{14}O_8Br_2$ : Br, 30.89. Found: 30.87, 30.91.

**5-Acetoxy-8-hydroxy-2,3-dibromo-1,4-naphthoquinone (F).**  $C_{18}H_8O_5Br_2.OH.COCH_3$ .—The acetylation of the dihydroxy-dibromo-naphthoquinone of Wheeler and

<sup>6</sup> Wheeler and Scott, Ref. 2.

Scott<sup>7</sup> affected only one hydroxyl group. Three g. was boiled in 30 cc. of acetic anhydride for 17 hours. The red solution gradually became yellow, and on cooling an abundant crystallization took place. On recrystallizing from glacial acetic acid light yellow prisms were obtained. These melted at 197° to a red liquid.

*Analyses.* Subs., 0.1678, 0.1203: AgBr, 0.1600, 0.1142. Calc. for  $C_{12}H_6O_5Br_3$ : Br, 40.99. Found: 40.40, 40.58.

**1,4,5-Trihydroxy-2,3,8-tribromo-naphthalene (G).**  $C_{10}H_3(OH)_3Br_3$ .—The reduction of tribromo-juglone in acid solution is carried out as follows. To 2 g. of tribromo-juglone dissolved in 25 cc. of ether is added some 1:5 sulfuric acid and small portions of zinc dust at short intervals, the flask being well shaken. The reddish solution soon becomes pale yellow. The ether layer is separated and washed several times with water. To avoid decomposition of the product the ether is allowed to evaporate at room temperature. The crude product weighs 1.7 g., is grayish-green in color and melts at 105–106°. After recrystallizing from benzene it melts at 106–107°, and retains its light grayish-green color. It crystallizes in clusters of needles, and is soluble in ether and alcohol and slightly soluble in chloroform. It is acted upon by hot water, yielding a compound melting at 168°.

*Analyses.* Subs., 0.2022, 0.2130: AgBr, 0.2755, 0.2886. Calc. for  $C_{10}H_3O_3Br_3$ : Br, 58.11. Found: 57.98, 57.66.

A sodium salt could not be prepared by the ether-sodium carbonate method. The possibility of tautomerism caused us to try the action of ketone reagents such as hydroxylamine hydrochloride in alcoholic and in sodium hydroxide solution semicarbazine hydrochloride in potassium acetate solution (alcoholic) and nitrophenyl hydrazine. Semicarbazine alone gave a product. It was yellow and melted at 102–112° but a bromine analysis gave 39.57% instead of a calculated percentage of 51.06.

**1,4,5-Triacetoxy-2,3,8-tribromo-naphthalene (H).**  $C_{16}H_3O_6Br_3$ .—A solution of 2 g. of trihydroxy-tribromo-naphthalene in 20 cc. of acetic anhydride was boiled for 20 hours. The product crystallized on cooling as a mass of very pale yellow crystals which weighed 1.3 g. and melted at 218–220°. Recrystallization from glacial acetic acid raised the melting point to 219–220°. The crystals are very pale yellow prisms.

*Analyses.* Subs., 0.1867, 0.2303: AgBr, 0.1930, 0.2375. Calc. for  $C_{16}H_3O_6Br_3$ : Br, 44.53. Found: 43.99, 43.87.

**5-Methoxy-8-hydroxy-2,3-dibromo-1,4-naphthoquinone (J).**  $C_{10}H_2O_4Br_2OH.OCH_3$ .—Four g. of the sodium salt of tribromo-juglone was added to 800 cc. of absolute methyl alcohol containing 2 cc. of methyl iodide, and boiled under a reflux condenser for 15 hours. The purple solution after some hours gradually became red. After filtration the solution was concentrated to 25 cc. and cooled. A brick colored precipitate separated, and was filtered off and washed with a little methyl alcohol. The product weighed 3.6 g. and after recrystallizing from benzene it melted at 209–210°. The crystals are plates of a light golden-red color.

*Analysis.* Subs., 0.1533: AgBr, 0.1580. Calc. for  $C_{11}H_2O_4Br_2$ : Br, 44.20. Found: 43.86.

An attempt was made to prepare the sodium salt by shaking an ether solution with a concentrated sodium carbonate solution. The yield was small, amounting to only 15% and the content of sodium was 7.94% instead of 5.92. It appeared to change on exposure to air.

**5-Ethoxy-8-hydroxy-2,3-dibromo-1,4-naphthoquinone (K).**  $C_{10}H_2O_4Br_2OH.OCH_2CH_3$ .—Four g. of tribromo-juglone was dissolved in 1200 cc. of ether and shaken vigorously for 15 minutes with a solution of 8 g. of sodium carbonate in 80 cc. of water. The

<sup>7</sup> Ref. 6, p. 840.

precipitated sodium salt was filtered off, dried and then added to a solution of the calculated amount of ethyl iodide in 250 cc. of absolute alcohol. The solution is boiled, remains violet in color many hours and finally after 10 hours becomes reddish yellow. After concentration to 50 cc. and cooling, a light brown precipitate, weighing 3.5 g., is obtained. The crystals are thin yellow plates, some with sharply pointed ends, and melt at 134–136°. The best solvent is alcohol.

*Analyses.* Subs., 0.1959, 0.2037: AgBr, 0.1936, 0.2008. Calc. for  $C_{12}H_8O_2Br_2$ : Br, 42.55. Found: 42.06, 41.95.

The loss of one bromine atom was due to the fact that boiling alcohol removed it as demonstrated by a special experiment. Tribromo-juglone was boiled with alcohol and then gave a precipitate of silver bromide with silver nitrate.

*The Sodium Salt.*  $C_{12}H_7O_2Br_2Na$ .—One g. of the ethoxy compound, dissolved in 200 cc. of ether, was shaken for 30 minutes with 2 g. of sodium carbonate in 20 cc. of water. The reddish-purple precipitate was filtered off, washed with dil. sodium carbonate solution and ether. It dyes silk a champagne color.

*Analysis.* Subs., 0.1406:  $Na_2SO_4$ , 0.0269. Calc. for  $C_{12}H_7O_2Br_2Na$ : Na, 5.80. Found: 6.20.

5-Acetoxy-8-chloro-2,3-dibromo-1,4-naphthoquinone (M).  $C_{10}H_6O_2Br_2Cl.O.COCH_3$ .—The chloro compound described by Wheeler and Scott<sup>8</sup> was boiled with acetic anhydride for 16 hours. Dilution with water gave a mass of yellow crystals which weighed somewhat more than the chloro compound used. The product crystallized from alcohol in long light yellow prisms which melted at 159.5–160°. It is very soluble in glacial acetic acid and ether.

*Analyses.* Subs., 0.1896, 0.1563: AgBr+AgCl, 0.2554, 0.2023. Calc. for  $C_{12}H_6O_4ClBr_2$ : Cl, 8.68; Br, 39.14. If Br is assumed as correct, then Cl found is 9.27, 9.22.

8-Anilino-5-hydroxy-2,3-dibromo-1,4-naphthoquinone (N).  $C_{10}H_6O_2Br_2OH.NHC_6H_5$ .—One g. of tribromo-juglone was dissolved in 350 cc. of alcohol containing an equivalent of aniline. The solution was heated for 6 hours on a steam-bath. Crystals formed during the boiling. The yield obtained on cooling and filtering amounted to 0.8 g. The product melted at 234.5–235.5° to a red liquid and consisted of reddish-brown crystals which were rectangular with irregularly broken ends, like chips of bark. The reaction was carried out with two equivalents of aniline but the same product was obtained. The labile bromine atom at Position 8 only is affected.

*Analyses.* Subs., 0.2246, 0.2133: AgBr, 0.2010, 0.1900. Calc. for  $C_{16}H_9O_2NBr_2$ : Br, 37.82. Found: 38.10, 37.92.

8-*o*-Toluidino-5-hydroxy-2,3-dibromo-1,4-naphthoquinone (O).  $C_{10}H_6O_2Br_2OH.NHC_6H_4CH_3$ .—The *o*-toluidine derivative was prepared as described in the preceding paragraph. One g. of tribromo-juglone gave a product weighing 0.76 g. This was recrystallized from 50 cc. of acetone. The pure substance melts at 187.5–189° and consists of reddish-brown flat crystals slightly tapering to broad ends like a steel spatula.

*Analysis.* Subs., 0.1565: AgBr, 0.1353. Calc. for  $C_{17}H_{11}O_2NBr_2$ : Br, 36.61. Found: 36.80.

8-*p*-Toluidino-5-hydroxy-2,3-dibromo-1,4-naphthoquinone (P).  $C_{10}H_6O_2Br_2OH.NHC_6H_4CH_3$ .—The reaction with *p*-toluidine gave a yield of 96% of the weight of tribromo-juglone taken. The product crystallized in the hot solution. It was recrystallized from 150 parts of acetone and consisted of reddish-brown rectangular plates, melting at 216–217°. It is very soluble in ether and only slightly soluble in alcohol.

<sup>8</sup> Wheeler and Scott, Ref. 2.

*Analysis.* Subs., 0.2212: AgBr, 0.1911. Calc. for  $C_{17}H_{11}O_2NBr_2$ : Br, 36.61. Found: 36.76.

**8-*p*-Bromo-anilino-5-hydroxy-2,3-dibromo-1,4-naphthoquinone (Q).**  $C_{16}H_8O_2Br_2OH \cdot NHC_6H_4Br$ .—One g. of tribromo-juglone was boiled with 350 cc. of alcohol containing one molecule of *p*-bromo-aniline. A voluminous precipitation took place during the heating. The crude product weighed 1.2 g. and melted at 253–256°. After crystallizing twice from 75 cc. of acetone the melting point was raised only to 254–256°. The product consists of long prismatic needles of reddish-brown color, difficultly soluble in alcohol and ether.

*Analysis.* Subs., 0.1500: AgBr, 0.1691. Calc. for  $C_{16}H_8O_2NBr_2$ : Br, 47.81. Found: 47.99.

**Reaction with *p*-Nitro-aniline.**—An attempt was made to carry out the reaction with *p*-nitro-aniline. One g. of tribromo-juglone gave a yellow product weighing 0.68 g. and melting at 159.5–160° after recrystallizing twice from 50 cc. of acetone. The crystals are short yellow prismatic needles. Two determinations of bromine gave very high results, 52.31% and 52.25% instead of 34.18% calculated. We are unable to explain this at present.

**Coupling with a Diazo Compound.**—The sodium salt of tribromo-juglone was added to a diazotized solution of aniline at 0°. The product was recrystallized from alcohol, was brick-red and melted at 145–147°. No test, however, could be obtained to indicate the presence of nitrogen.

### Summary.

1. Tribromo-juglone possesses a very reactive bromine atom at Position 8. It was replaced by the following groups: OH, Cl,  $NHC_6H_5$ ,  $NHC_6H_4CH_3$  (*o*),  $NHC_6H_4CH_3$  (*p*),  $NHC_6H_4Br$  (*p*).
2. The quinone oxygens are reduced to hydroxyl groups by zinc dust in acid solution, giving a tribromo-trihydroxy-naphthalene.
3. If the bromine at Position 8 is first replaced by an hydroxyl group, then (1) zinc dust in acid solution gives tetrahydroxy-dibromo-naphthalene and (2) zinc dust in alkaline solution gives a tetrahydroxy-naphthalene.
4. The acetyl derivatives of all compounds containing an hydroxyl group were prepared.
5. The sodium salt of tribromo-juglone gave ethers on boiling with alkyl halides.
6. Compounds containing the quinoid complex and one or more hydroxyl groups are dyes.
7. All compounds described are new.

# THE INFLUENCE OF GLUCOSE ON THE DIALYSIS OF SUCROSE THROUGH A PARCHMENT MEMBRANE. THE POSSIBILITY OF THE SEPARATION OF GLUCOSE FROM SUCROSE BY DIALYSIS.

BY LEON A. CONGDON AND HARRY R. INGERSOLL.

Received July 25, 1921.

## Introduction.

A study of the literature has shown that the separation of glucose from sucrose by dialysis has never been attempted. Pfeffer in his classical experiments<sup>1</sup> upon osmosis in vegetable cells discovered that the osmotic pressure of dilute sugar solutions was proportional to the concentration, and that the osmotic pressure of sugar solutions underwent a regular increase with increase of temperature. And in a practical way, Dubrunfaut devised the old osmose process<sup>2</sup> for recovering sucrose from beet molasses. If beet molasses be dialyzed by means of parchment paper against running water the salts will diffuse with much greater rapidity than the sucrose and in this way the percentage of melassigenic impurities can be considerably reduced; beet molasses thus purified will deposit upon evaporation crystals of sucrose up to the new saturation point for the solution of undialyzed impurities. This process has given place technically to the saccharate process of sucrose recovery.

O. A. Val'tera<sup>3</sup> has made use of the separation by dialysis in his study of enzymes.

In order to obtain information as to whether sucrose and glucose in mixtures could be separated by dialysis and what effect glucose had on the dialysis of sucrose, five different solutions, each containing a mixture of sucrose and glucose were dialyzed through parchment paper.

## Experimental.

The materials to be dialyzed were sucrose and glucose, each containing less than 1% of impurities. Mixtures of sucrose and glucose were made up as follows: 2 g. each of sucrose and glucose in 100 cc. of distilled water; 10 g. of glucose and 25 g. of sucrose made up to 100 cc. with water; 5 g. of glucose and 25 g. of sucrose made up to 100 cc. with water; 0.5 g. of glucose and 25 g. of sucrose made up to 100 cc. with water. For the purpose of dialysis, 25 cc. of each of the above solutions was taken, and diluted to  $\frac{1}{4}$  strength for dialysis.

The dialysis was made through a parchment paper membrane. The parchment tube was made about 12.5 cm. long and 5 cm. in diameter.

<sup>1</sup> Pfeffer's "Osmotische Untersuchungen," Leipzig, 1877.

<sup>2</sup> C. A. Browne, "A Handbook of Sugar Analysis," J. Wiley and Sons Co., 1912, p. 649.

<sup>3</sup> Val'tera, "A method of Dialysis of Enzymes," *Bull. Acad. Sci. Russ.*, 1917, (6), No. 13, pp. 1075-88, abs. *Exper. Sta. Record*, 40, 111 (1921).

A solid rubber stopper was fitted into one end of the parchment tube and cemented there with paraffin. Sealing wax was first used but it was found that the wax spread on hardening and caused leaks in the joints. A 1-holed rubber stopper was fitted into the other end of the parchment tube. The sugar solution was passed into the tube by means of a 25cc. pipet. The dialysis tube was then placed in a narrow beaker and 150 cc. of distilled water was run into the beaker, thus surrounding the parchment tube. Five-cc. portions of the solution were withdrawn, two at a time, at definite intervals and placed in test-tubes. At each removal, the sucrose in one of these samples was inverted by adding 5 drops of dil. hydrochloric acid.

Bertrand's method, with slight modifications, was used in analyzing the samples. Five cc. of copper sulfate solution (from 140 g. of pure copper sulfate pentahydrate dissolved in 1000 cc. of water) and 5 cc. of a solution made up of Rochelle salt and 150 g. of solid sodium hydroxide dissolved in 1000 cc. of water were added to each of the 5 cc. samples to be analyzed. The resulting solution was placed in a small beaker and boiled for 3 minutes. The solution was filtered through asbestos in a Gooch crucible and the precipitate of cuprous oxide was washed with distilled water. The asbestos film was transferred to a beaker and 30 cc. of hot water added. The Gooch crucible was rinsed out with a hot saturated solution of ferric sulfate in 20% sulfuric acid and the rinsing run into the beaker containing the precipitate. The cuprous oxide was changed to copper sulfate by the ferric sulfate solution, a corresponding amount of which was reduced to the ferrous state. The solution was now titrated with standard potassium permanganate. The ferrous sulfate was thus oxidized to the ferric condition. By calculation the amount of cuprous oxide precipitate was determined for each sample and from this the amount of sugar corresponding to the amount of precipitated copper.

The following tables and graphs show the results of the work. The dialysis was conducted at the temperature of the laboratory, about 22.5°.

### Discussion of Results.

The results with these varying concentrations show that glucose dialyzed faster than sucrose. The influence of glucose on the dialysis of sucrose is of such a character as to keep the ratio of glucose to sucrose approximately constant after 3 hours of dialysis, irrespective of the concentration of the sucrose to be dialyzed. This can be plainly seen in Fig. 4. In Fig. 3 it is evident that the rate of the dialysis of glucose increases as the concentration of the glucose decreases, the concentration of the sucrose remaining the same.

The ratio of the percentage of the glucose to the percentage of the sucrose dialyzed is fairly constant, as seen in Tables I A, B and C, after 3 hours of dialysis; but on using a very small concentration of glucose, as in Table I D, the ratio increases approximately 2.0 times its former value.

The ratio of the dialysis of glucose to sucrose was found to be 2.5 to 1 respectively in solutions of glucose of 2% or greater; but in more dilute

Average <sup>a</sup>							2.5	2.8	7.1

<sup>a</sup> The average is rather constant if the figures after 3 hours of dialysis are taken. In the case of the average after 3 hours of dialysis, we have for Table I B:—2.4; I C:—2.5, and I D:—4.7; and if we take the average after 3 hours of dialysis for Table I A probable experimental errors excluded, we have 2.0 for the approximate ratio of glucose to sucrose dialyzed.

Fig. 1.—In parchment tube, 25 cc. of a solution of 2% of glucose and 2% of sucrose; dialyzed into 150 cc. of water.

A = % of the glucose dialyzed; B = % of the sucrose dialyzed.

Fig. 2.—In parchment tube, 25 cc. of a solution of 0.5% of glucose and 25% of sucrose; dialyzed into 150 cc. of water.

A = % of the glucose dialyzed; B = % of the sucrose dialyzed.

Grams glucose plus 6.25 grams sucrose in tube.

Fig. 3.—AG = % of glucose dialyzed in 24.5 hours; BG, in 7.0 hours; CG, in 3.0 hours.

AS = % of sucrose dialyzed in 24.5 hours; BS, in 7.0 hours; CS, in 3.0 hours.

It is shown that in very dilute mixtures of glucose and sucrose, the former can be separated qualitatively from the latter by dialysis in about 51 hours (see Fig. 2). There is a possibility of a quantitative separation of glucose from sucrose by fractional dialysis.

Fig. 4.—A represents 25 cc. of a solution of 10% of glucose and 25% of sucrose, dialyzed into 150 cc. of water through a parchment membrane; average after 3 hours of dialysis.  
 B=25 cc. of a solution of 5% of glucose and 25% of sucrose;  
 C=25 cc. of a solution of 0.5% of glucose and 25% of sucrose;  
 D=25 cc. of a solution of 2% of glucose and 2% of sucrose.

### Summary.

1. Five mixtures of sucrose and glucose solutions were dialyzed through parchment paper under standardized conditions and the following general facts developed as a result of the data obtained.

(a) The percentages of glucose and sucrose dialyzed in mixtures of solutions of these two substances vary inversely as the concentrations in the original solutions.

(b) In mixtures of glucose and sucrose, the influence of glucose on the dialysis of sucrose is of such a character as to keep the ratio of glucose to sucrose dialyzed approximately constant, irrespective of the concentration of the sucrose to be dialyzed, provided that the concentration of the glucose is not less than 2%, and the time of dialysis has exceeded 3 hours. In dialysis of solutions of less than 2% glucose, the glucose dialyzes much faster than at the above rate, and in 0.125% glucose solution the rate of the percentage of the glucose to that of the sucrose dialyzed is 5.0 to 1, respectively, this being 2.0 times as great a rate as in solutions of 2% or more glucose. Hence, glucose dialyzes faster than sucrose.

(c) In very dilute mixtures of glucose and sucrose, the former can be separated qualitatively from the latter by dialysis in about 51 hours. There is a possibility of a quantitative separation of glucose from sucrose by fractional dialysis.

(d) The above results apply to dilute solutions within the range covered by the experimental work.

2. The rate of dialysis was determined by removing definite volumes of the dialyzed solution at recorded intervals and inverting one portion of the removed samples to determine the percentage of sucrose calculated from the portion that was inverted.

3. Bertrand's method of analysis was used.

## SYMMETRICAL DI-ISOPROPYL-HYDRAZINE AND ITS DERIVATIVES.

(Preliminary Article.)

By HARRY L. LOCHTE WITH JAMES R. BAILEY AND WILLIAM A. NOYES.

Received July 26, 1921.

### Introduction.

Little work has been done on the purely aliphatic symmetrical hydrazines or hydrazo compounds and, with the exception of the stable azomethane<sup>1</sup> and certain azo derivatives of isobutyric acid,<sup>2</sup> the corresponding azo derivatives are unknown. Harries<sup>3</sup> could not isolate azoethane, and Franke<sup>4</sup> who obtained a small amount of symmetrical diisobutylhydrazine, evidently did not have enough material to study this compound at all thoroughly. Busch, in working with the latter hydrazine<sup>5</sup> does not mention the azo compound. He reports that Stolle and his coworkers made symmetrical hydrazines, but there seem to be no published articles available on this work.

The azines which are so easily prepared from hydrazine through its reaction with aldehydes and ketones, both aliphatic and aromatic, might be expected to yield, on reduction, the corresponding hydrazo compounds and thus furnish a readily available source for these substances. In some cases the reduction proceeds smoothly; *e. g.*, symmetrical benzylhydrazine ( $C_6H_5CH_2NHNHCH_2C_6H_5$ ) is easily prepared from benzalazine, ( $C_6H_5CH=N-N=CH-C_6H_5$ ). However, up to the present the reduction, in this sense, of aliphatic aldazines and ketazines has failed. Curtius, who discovered dimethyl-ketazine<sup>6</sup> ( $((CH_3)_2>C=N-N=C$

$<(\text{CH}_3)_2$ ) tried to reduce it to the symmetrical hydrazine, but he found that it is very easily decomposed into acetone and hydrazine in acid solution while alkaline reducing agents had no effect on the ketazine. Thiele attempted<sup>7</sup> to reduce this same azine, but obtained negative results with electrolytic methods he found satisfactory for the reduction of benzalazine. He also tried to prepare symmetrical di-*isopropyl*-hydrazine<sup>8</sup> through the elimination of two molecules of carbon dioxide from *isobutyric* acid, but did not succeed. Wieland<sup>9</sup> reports that the purely aliphatic aldazines are not reducible. (Presumably ketazines would be included in this statement.) It remained for Mailhe,<sup>10</sup> quite recently, to reduce ketazines. He used the Sabatier-Senderens method of catalytic reduction over hot nickel. The results obtained are of little interest however, because the main products isolated were mono- and di-*isopropylamine*.

We have become convinced, through work at the University of Texas and a continuation of this at the University of Illinois, that dimethyl-ketazine does not yield the symmetrical hydrazine with any of the ordinary neutral or alkaline reducing agents, such as aluminum amalgam, iron powder, sodium in alcoholic solution, sodium amalgam in neutral or alkaline solution, and sodium and alcohol in the presence of boric acid.

Recently, in the laboratory of the University of Texas, an exhaustive research on the use of colloidal platinum, according to the method of Skita,<sup>11</sup> in the reduction of azines and semicarbazones was begun. The present paper deals with the reduction of dimethyl-ketazine by this method and the process gives, in a yield of over 90%, symmetrical di-*isopropyl*-hydrazine that Curtius, Thiele, and Mailhe were unable to prepare by other methods of reduction. It is now possible to produce this interesting substance with little labor, in any amount desired and, no doubt, an expansion of this reaction will make available a whole series of hydrazo aliphatic hydrocarbons.

From the work of Rupe and Oestreich<sup>12</sup> it is evident that the reduction of semicarbazones presents difficulties similar to those that were encountered in the case of azines but it appears probable that the Skita method of reduction will also be found effective here.<sup>13</sup>

<sup>12</sup> Rupe and Oestreich, *ibid.*, 45, 30 (1912).

<sup>13</sup> Neighbors and Bailey working in the laboratory of the University of Texas find that acetone semicarbazone yields very smoothly, on reduction with colloidal platinum as catalyst, carbon-amido-hydrazo-propane. A description of this phase of the work will appear shortly in *THIS JOURNAL*.

Although catalytic reduction, using platinum or palladium as catalyst and hydrogen gas as reducing agent, has been known for half a century, the possibilities of this method of reduction were not fully recognized until after the year 1900, and intensive investigation with this form of catalytic reduction really was begun in 1908. During this period three main methods were worked out: (1) the Willstätter method,<sup>14</sup> using platinum black prepared according to Low;<sup>15</sup> (2) the Paal method,<sup>16</sup> using colloidal palladium or platinum protected by the sodium salt of protalbinic or lysalbinic acid, available only for reduction in neutral or alkaline solutions; (3) the Skita method,<sup>17</sup> using gum arabic as protective colloid instead of Paal's protalbinic or lysalbinic acid. The gum arabic stabilizes the colloid in such a way that the reduction may be carried out in neutral, alkaline, or acid solution while at the end of the run the colloid is easily broken by the addition of acetone. Skita furthermore originated the principle of inoculation in catalytic reduction;<sup>18</sup> a small amount of platinic or palladous chloride is reduced separately and a few cubic centimeters of this stock solution can be employed as "seeding" colloid that aids in reducing the main mass of platinum, which, in turn, catalyzes the reduction of the substance in question.

The Skita method was selected as a promising one for the reduction of azines and has proved successful from the start. However, at first it was necessary to employ as much as 100 cc. of 10% chloroplatinic acid for every 100 cc. of ketazine. Even then with this large amount of platinum the yield was only about 80% and several days were required for completion of the reduction. In attempting to improve the yield or, at least, to reduce the amount of platinum used, it was found that partial neutralization of the base formed as the reduction proceeds immensely accelerates the reduction and makes it possible to complete this in a single day with less than a fourth of the platinum formerly used. The extra chloroplatinic acid used in our initial experiments probably owed its main effect to the hydrochloric acid liberated in this reduction rather than to the additional amount of colloidal platinum it added to the reduction mixture. Since then an article, by Skita, has appeared<sup>19</sup> in which he makes the same observation on the effect of hydrochloric acid in a similar

<sup>19</sup> Skita, *ibid.*, 52, 1521 (1919).

case. Further experience in these laboratories indicates that addition of hydrochloric acid is always necessary when a base is formed by catalytic reduction.

In experiments now in progress, it is found that addition of the theoretical amount of hydrochloric acid at the beginning of the run in no way diminishes the yield of 90 to 95% (based on the amount of ketazine used) that is obtained by keeping the solution only partially neutralized. Since this seems to indicate that the ketazine is not hydrolyzed appreciably by dilute acid under the conditions of our experiments, the catalytic reduction of a mixture of 1 mol of hydrazine hydrate, 1 mol. of hydrochloric acid, and 2 mols of acetone should give good results while at the same time obviating the isolation, with rather unsatisfactory yields, of dimethyl-ketazine. Three preliminary runs using, in each, 25 g. of hydrazine hydrate in 250 cc. of water gave 78, 80, and 74 g. of the hydrochloride of symmetrical di-isopropyl-hydrazine. Although only once recrystallized from alcohol, samples of this salt melted at 197–198°, had a chlorine content of 23.8% (by titration with silver nitrate), and 3 iodine titrations gave an average purity of 95.3% (2 atoms of iodine to 1 mol of the hydrazine) showing that the salt is practically pure and the yield very nearly quantitative (based on the hydrazine hydrate used), while the time required for this reduction is only 3 to 4 hours.

The hydrazo compound formed in the reduction of dimethyl-ketazine is similar to the other symmetrical hydrazines in its physical properties. It is difficult to obtain the base completely anhydrous, and it is very easily oxidized. In all reactions so far observed it is monobasic. The behavior of the base towards mild oxidizing agents is different from that of other compounds of this series.

Work on other reactions of this hydrazine and on its various oxidation products is being continued in this laboratory. It is also planned to reduce other azines of the aliphatic series, especially acetaldazine and methyl-ethyl-ketazine or methyl butyl-ketazine.

### Experimental Part.

**Reduction of Dimethyl-ketazine.**—The initial reductions were carried out on dimethyl-ketazine prepared according to the method of Curtius and Zinkeisen.<sup>20</sup> Since the yields of ketazine were only from 60 to 70% of those expected from the amount of hydrazine sulfate used, the isolation of the ketazine has been abandoned and present runs are made on a mixture of hydrazine hydrate, acetone, and hydrochloric acid. The hydrochloric acid was found necessary in case of the initial experiments and its use is essential also in runs as now made.

<sup>20</sup> Curtius and Zinkeisen, *J. prakt. Chem.*, [2] 53, 315 (1898).

The Skita apparatus<sup>21</sup> is used, the container for the reduction mixture being a liter flask. This bottle is charged with 25 g. of hydrazine hydrate (calculated from iodine titration, according to the method of Stolle,<sup>22</sup> of a solution of the hydrate) in 100 cc. of water. To this is added a mixture of 0.5 g. of gum arabic dissolved in 50 cc. of water and 10 cc. of chloroplatinic acid. The "seeding" colloid is next prepared by mixing 10 cc. of water, a few drops of gum arabic solution, 5 cc. of chloroplatinic acid, 0.5 cc. of 30% sodium hydroxide, and a few crystals of the hydrochloride of symmetrical di-isopropyl-hydrazine, or some other equally good reducing agent. On heating this mixture, reduction of the platinum begins at once. The hot mixture is rapidly added to the solution in the flask, to which are then added, under thorough shaking of the flask, 100 cc. of 18.5% hydrochloric acid and finally 100 cc. of acetone. The flask is then connected to the apparatus, the system evacuated and filled with hydrogen from a cylinder, until the apparatus is under a total pressure of 2 atmospheres. The hydrogen cylinder should be supplied with a reducing valve to prevent accidents and damage to the apparatus in filling the reservoir and flask.

The room temperature, hydrogen pressure, atmospheric pressure, and gage readings are now recorded and the shaker started. During the few minutes required for the reduction of the chloroplatinic acid the absorption is relatively slow, but as reduction of the platinum proceeds the rate of absorption increases until the gas is used up at the rate of 8 to 12 liters an hour. As reduction proceeds the absorption of hydrogen gradually slows down and comes to a complete stop at the end of 3 to 4 hours, when the theoretical amount of hydrogen has been absorbed. Enough heat is generated to keep the reduction mixture at a temperature of about 45° during the first 2 hours of the run. In case of poisoning of catalyst or other cause of slow reduction an additional 5 cc. of chloroplatinic acid is sometimes required to complete the reduction. As stated in the introductory part of this paper, the yields on 3 consecutive runs using, in each, the amount of hydrazine hydrate given above, gave yields of 78, 80, and 74 g. of hydrochloride of symmetrical di-isopropyl-hydrazine.

This salt is of about 93% purity so that the yield is practically quantitative, as the calculated yield is 76.2 g. of the hydrochloride.

**Symmetrical Diisopropyl-hydrazine.**—The reaction mixture, from the machine, is treated with acetone until the platinum and gum arabic precipitate together in the form of flakes, then filtered through a pleated filter, the filtrate acidified with hydrochloric acid and the solution evaporated to dryness *in vacuo* on a water-bath. The crude hydrochloride is slightly yellow and hygroscopic, but after recrystallization from alcohol the salt is pure white and nonhygroscopic. The free base is obtained from the salt by treatment with concentrated sodium hydroxide, the yellow oily layer separated, dried for 12 to 15 hours over solid potassium hydroxide, the base again separated and dried for 1 day with aluminum amalgam. The oil is then rapidly filtered from the inorganic material and fractionated. The base is now of a light straw color and distills between 110° and 124.5° as a colorless mobile liquid of ammoniacal, ethereal odor. A complete analysis of the 124° to 124.5° fraction as well as hydrochloric acid and iodine titrations shows this to be the pure symmetrical diisopropyl hydrazine. Even air very readily oxidizes this hy-

<sup>21</sup> Skita and Meyer, *Ber.*, 45, 3589 (1912).

<sup>22</sup> Stolle, *J. prakt. Chem.*, [2] 66, 332 (1902)

drazo compound and this property makes aluminum amalgam far superior to barium oxide, which is usually employed as a dehydrating agent for hydrazines.<sup>23</sup> In attempts to dry with barium oxide as much as 50% of the base is often oxidized to the product boiling at 88.8°, and even when an inert gas is kept over the mixture a considerable loss occurs.

The estimation of carbon and hydrogen in symmetrical diisopropyl-hydrazine presents certain difficulties which may be overcome by running the combustion very slowly on a gas furnace under the following conditions. In the beginning with only the burners next to the absorption apparatus lighted, a very slow stream of air (oxygen causes small explosions) is passed through the tube and from time to time, after the liquid in the bulb begins to vaporize, an ice pack is applied to the bedplate immediately under the sample to keep down the tendency of the combustion to run wild. On the other hand when the vaporization does not proceed fast enough a hot tile is held over the sample for a few seconds. Through this alternate cooling and heating the rate of vaporization and combustion is very carefully regulated until all of the liquid has been expelled from the bulb. The tendency of the combustion to run wild is due to the ease with which the hydrazo compound and, to a lesser extent, its derivatives are oxidized, rather than to volatility. Franke<sup>4</sup> experienced a similar difficulty in the analysis of symmetrical diisobutyl-hydrazine with a boiling point of 170–175°. After the sample has been volatilized as described above, the combustion is completed in the usual manner.

*Analyses.* Calc. for  $C_6H_{12}N_2$ : C, 62.08; H, 13.80; N, 24.14. Found: C, 62.39, 62.17; H, 13.97, 14.31; N, 24° 54, 24.30.

This sample boiled at 124° to 124.5° under 740 mm.;  $n_D^{23^\circ}$ , 1.4087;  $d_4^{31^\circ}$ , 0.7712.

Since the substance is very easily oxidized, a convenient and rapid check on its purity is obtained by titration with iodine according to Stolle.<sup>22</sup>

**Hydrochloride of Symmetrical Diisopropyl-hydrazine.**—The crude product mentioned above, recrystallized 3 times from alcohol, is obtained in the form of colorless needles melting at 198° (corr.). It is readily soluble in water and alcohol and practically insoluble in ether, acetone and benzene. The salt, like the base, is readily attacked by all common oxidizing agents. A peculiar reaction in this connection is the quantitative oxidation of the dry hydrochloride by dry copper oxide to a product boiling at 88.8° under 740 mm. pressure. A mixture of the substances, after a few minutes, gives the characteristic odor of the oxidation product. After 24 hours it becomes pasty, and finally the greenish-straw colored product is present in such amount that the whole mass may be poured out of the flask. There are reasons for believing that this is the azo compound corresponding to the symmetrical diisopropyl-hydrazine, but work on this product is still in progress and will be reported in a later article.

The hydrochloride of diisopropyl-hydrazine is so easily oxidized that nitrogen determinations may be made by simply oxidizing the salt by means of a dichromate-sulfuric acid mixture and collecting the nitrogen as usual in wet methods. Kjeldahl determinations made in the ordinary manner as well as qualitative nitrogen tests fail because of the ease with which nitrogen is split out.

*Analyses.* Calc. for  $C_6H_{12}N_2Cl$ : Cl, 23.27; N, 18.36. Found: Cl (Carius) 22.99, (titration  $AgNO_3$ ) 23.77, 23.75, 23.78, 23.69; N, (Dumas) 18.21, (sulfuric-dichromate wet method) 18.15.

**Diisopropyl-phenylthio-semicarbazide**,  $(CH_3)_2CHNH(CSNC_6H_5)CH(CH_3)_2$ .—An aqueous solution of the base treated, under cooling, with phenyl mustard oil gives

Knorr and Kohler, *ibid.*, 39, 3259 (1906).

a good yield of a white flaky condensation product. Recrystallized from ether it melts at  $129.5^{\circ}$  (corr.). It is soluble in acetone, chloroform, benzene and ether and but slightly soluble in water, alcohol and ethyl acetate.

*Analyses.* Calc. for  $C_{12}H_{21}N_3S$ : S, 12.75; N, 16.74. Found: S(Carius) 12.45, 12.45; N, (Dumas) 16.73.

In addition to the compounds studied and analyzed the potassium cyanate and the phenyl-isocyanate condensation products and the oxalic acid salt are obtained as well crystallizing compounds, while the benzoyl compound shows no tendency to crystallize.

### Summary.<sup>24</sup>

1. Dimethyl-ketazine is reduced to the symmetrical diisopropylhydrazine by means of the Skita method of catalytic reduction.
2. The properties of the hydrazine and of some of its salts and derivatives are described.
3. Other derivatives and their reactions are being studied and are to be reported on in a later article.

## RESEARCHES ON PYRIMIDINES. XCI. ALKYLATION OF 2-MERCAPTO-PYRIMIDINES.

By WILLIAM J. HORN.<sup>1</sup>

Received July 28, 1921.

When a 2-mercapto-6-oxypyrimidine combination is subjected to alkylation in alkaline solution, it is susceptible to attack in three different positions and, at the present time, we have no law, or rule, which will permit one to predict the configuration most likely to be formed.

In most of the cases so far examined<sup>2</sup> where the radical, R, of the 2-mer-

<sup>24</sup> The preparation of symmetrical diisopropyl hydrazine was effected by Bailey and Lochte at the University of Texas and the work was transferred later by Mr. Lochte to the University of Illinois. Professor Bailey prefers the name 2-hydrazopropane.

<sup>1</sup> This paper was constructed from a dissertation presented by William John Horn to the Faculty of the Graduate School of Yale University, in June, 1921, in candidacy for the degree of Doctor of Philosophy. (T. B. Johnson).

capto group has been strongly positive in nature, the alkylation reactions have been productive quite generally of isomeric 1- and 3-nitrogen substituted pyrimidines, and there seems to be no regularity in the proportion in which such isomers are produced. Regarding the mechanism of these reactions we have no very positive evidence, but it has been assumed as very probable, that all these changes take place primarily by addition of the alkyl halide to the sodium salt of the pyrimidine, which is followed by dissociation of the resulting polymolecular combination giving the alkylated pyrimidine as the final product of reaction. The configuration obtained will depend entirely upon the constitution of the primary addition product.

In some cases, however, it has been observed,<sup>3,4</sup> especially when the radical R of the 2-mercapto group is negative in character, that the product of alkylation is not a nitrogen pyrimidine derivative, but one in which the substitution of the alkyl group has taken place on oxygen in the 6-position of the pyrimidine cycle with formation of an alkoxyl or imido ester combination. Such transformations may be interpreted as taking place through direct substitution, although it is not improbable that the addition theory of reaction may apply also in these cases. In fact, the results obtained by Johnson and Moran<sup>4</sup> on pyrimidine alkylations, where alcoholysis of imido ester combinations was observed to take place, would seem to be very strong evidence in support of the fact that we have to deal with intermediate addition products in this type of change also.

We now describe in this paper another series of alkylation experiments which have revealed further abnormalities in chemical behavior during the process of alkylation. We have substituted the negative radical, *p*-nitrobenzyl,  $\text{NO}_2\text{C}_6\text{H}_4\text{CH}_2$  for R and synthesized the mercapto-pyrimidine represented by Formula I. This compound is easily prepared by the action of *p*-nitrobenzyl chloride on the sodium salt of 2-thio-4-methyluracil.

Alkylation of this 2-mercapto-pyrimidine (I) with methyl iodide leads to the formation of two products which are not isomeric. The data thus far obtained indicate that the methyl group substitutes in methyl alcohol solution to give only one product, namely, 1,4-dimethyl-2-*p*-nitrobenzyl-mercapto-6-oxypyrimidine, (V). The structure of this compound was established by its behavior on hydrolysis when it was found to be transformed smoothly into *p*-nitrobenzyl mercaptan (VII) and 1,4-dimethyluracil (VI). We obtained no evidence of the formation of an isomeric, 3,4-dimethyl-2-*p*-nitrobenzyl-mercapto-6-oxypyrimidine or an imido ester combination resulting from substitution on oxygen in the 6-position of the ring.

<sup>3</sup> Johnson and Haggard, *THIS JOURNAL*, 37, 177 (1915).

<sup>4</sup> Johnson and Moran, *ibid.*, 37, 2591 (1915).

The second product of reaction with methyl iodide proved to be an addition compound, which we have expressed by Formula II. Not only is this interesting substance formed by direct alkylation of (I) with an excess of methyl iodide, but the same combination results also by interaction of the pyrimidine V with methyl iodide when digested in methyl alcohol. Hydrolysis of this substance with hydrochloric acid led to the formation of 1,4-dimethyluracil (VI), proving that the second methyl group does not link itself to nitrogen. The choice between the two other possible linkings, namely, addition to sulfur of the mercapto group or oxygen in the 6-position of the ring was indicated by the behavior on hydrolysis. By this treatment the mercapto group of the addition compound was replaced and identified as *p*-nitrobenzyl disulfide (IV). This sulfide is formed by oxidation of nitrobenzyl mercaptan, a change that is brought about by the influence of traces of iodine also formed as a product of hydrolytic change. In other words, we obtained no evidence of the formation by hydrolysis of the sulfide  $\text{NO}_2\text{C}_6\text{H}_4\text{CH}_2\text{SCH}_3$ .<sup>5</sup>

<sup>5</sup> The study of these addition compounds will receive attention in the immediate future. (T. B. J.)

This is the first case to be described where we have been able to isolate an addition product of this type, and the result indicates that such combinations have probably resulted in previous condensations and that their formation is a partial explanation of the low yields and abnormal results obtained in many cases. Johnson and Jones<sup>6</sup> have shown that the pyrimidine, 2-ethyl-mercapto-3-methyl-5-ethoxy-6-oxypyrimidine, combines with potassium iodide to form a characteristic addition product. Our addition product, II, was absolutely free from inorganic material.

The fact that iodine is formed by hydrolysis of the addition product (II) in acid solution is strong evidence that the alkyl halide has dissociated in the process of addition to the pyrimidine and this condition is expressed by the structural formula assigned. The identification of this addition product is strong evidence in support of the assumption that all these alkylations in the pyrimidine series probably operate through the intermediate formation of addition compounds.

Ethyl bromide and allyl bromide interact with the sodium salt of the mercapto-pyrimidine in an entirely different manner from methyl iodide. In neither case did we observe the formation of nitrogen-substituted derivatives, but both halides interacted to form imido ester combinations. The structures of these compounds are expressed by Formulas VIII and IX respectively. The constitution of both of these pyrimidines was established by the fact that they underwent hydrolysis with formation of 4-methyluracil and nitrobenzyl-mercaptan.

In the experimental part of this paper are recorded some new facts bearing on the chemistry of *p*-nitrobenzyl-mercaptan and its corresponding sulfide derivatives.

### Experimental Part.

**2-Thio-4-methyluracil and *p*-Nitrobenzyl Chloride.**—The method employed for the preparation of 2-thio-4-methyluracil was that used by Wheeler and McFarland;<sup>7</sup> *p*-nitro-benzyl chloride was prepared according to the directions of Alway.<sup>8</sup>

**2-*p*-Nitrobenzyl-mercapto-4-methyl-6-oxypyrimidine. (I).**—This pyrimidine was obtained in quantity by the action of *p*-nitrobenzyl chloride upon the sodium salt of 2-thio-4-methyl-uracil.

To sodium ethylate solution, prepared by dissolving a molecular proportion of sodium in absolute alcohol, finely pulverized 2-thio-4-methyl-uracil was added. On heating this mixture for two hours and shaking occasionally, the sodium salt separated and the solution became reddish-yellow in color. *p*-Nitrobenzyl chloride was then added and the resulting solution was heated until it became neutral. The solution, turned green at first and then dark red. After it had been heated for about 20 minutes it solidified to a white cake. At the end of the reaction, the mixture was cooled, filtered with the aid of suction and the crystalline product was treated with cold water to dissolve the sodium chloride formed in the reaction. The yield of crude pyrimidine was

93%. This compound is only slightly soluble in hot alcohol and difficultly soluble in hot water. It was purified by recrystallization from glacial acetic acid, from which it separated in the form of rosetts of colorless needles. These were collected on a filter, washed, first with a little acetic acid and then with water, and dried at 115° for 10 to 15 hours. By this procedure, an 80% yield of the pure compound was obtained; it melted at 220° to give a clear yellow oil.

*Analyses.* Calc. for  $C_{12}H_{11}O_3N_3S$ : N, 15.16; S, 11.55. Found: N, 15.24, 15.6; S, 11.42.

#### Alkylation of 2-*p*-Nitrobenzyl-mercapto-4-methyl-6-oxypyrimidine.

##### Action of Methyl Iodide.

To a sodium methylate solution, made by dissolving a molecular proportion of sodium in methyl alcohol, finely pulverized 2-*p*-nitrobenzyl-mercapto-4-methyl-6-oxypyrimidine was added and the clear greenish-yellow solution thus obtained was heated for one hour. By means of a dropping funnel, slightly more than the calculated quantity of methyl iodide was then added slowly to the warm solution of the sodium salt and the solution was heated until it became neutral. Upon removal of the alcohol by evaporation under diminished pressure, a greenish-yellow solid separated which had the odor of parsnips. This product was triturated with cold water to dissolve sodium iodide, and the insoluble material collected on a filter was dried in a vacuum desiccator over sulfuric acid for several days. This substance gave a very strong test for iodine on treatment with sulfuric acid. When the finely pulverized product was extracted in a Soxhlet apparatus with dry ether free from alcohol for 25 hours, it was separated into two distinct compounds, one of which (A) was soluble in ether and the other (B) insoluble.

(A) 1,4-Dimethyl-2-*p*-nitrobenzyl-mercapto-6-oxypyrimidine. (V).—On evaporating the ether solution containing the soluble compound (A) to dryness in the air, a yellow solid was obtained which represented 71.5% of the weight of the total alkylated products. This compound was free from iodine and melted between 90° and 111°. Upon recrystallization from glacial acetic acid, it was obtained in the form of rosetts of white needles which melted sharply at 136° to give a clear yellow oil. It was identified as a monomethyl derivative of the original pyrimidine.

*Analyses.* Calc. for  $C_{12}H_{13}O_3N_3S$ : N, 14.4. Found: 14.14, 14.16.

**HYDROLYSIS WITH HYDROCHLORIC ACID.**—The structure of this compound was established by its behavior on hydrolysis with conc. hydrochloric acid. One to three g. of the compound was digested in 100 cc. of the acid for several hours. In about 10 minutes, the boiling solution became turbid and a yellowish-brown oil separated on the surface of the liquid. At the end of the reaction period, the solution was filtered to remove the oil and the filtrate evaporated to dryness. By this procedure, a yellowish-white residue was obtained which melted at 256–258°; the yield was nearly quantitative for 1,4-dimethyluracil. After recrystallization from hot water and treatment with Norite, the substance was obtained in the form of colorless prismatic needles free from sulfur. These crystals melted sharply at 259–260° to give a clear red oil.

*Analyses.* Calc. for  $C_8H_8O_2N_2$ : N, 20.0. Found: 19.93, 19.72.

The yellowish-brown oil insoluble in water solidified as it cooled to give a pearl-white solid. Dried in a vacuum desiccator over sulfuric acid the substance was obtained in quantity corresponding very closely to the quantitative yield for *p*-nitrobenzyl-mercaptan. This compound is only very slightly soluble in water, but is very soluble in ether. It was purified by recrystallization from alcohol from which it separated in the form of white transparent plates melting sharply at 58° to a clear yellow oil. A molecular-weight determination was made by the freezing-point method.

*Analyses.* Calc. for  $C_7H_7O_2NS$ : N, 8.28; S, 18.93; Mol. wt., 169.0. Found: N, 8.13, 8.47; S, 18.54; Mol. wt., 160.2, 164.8.

A further description of this compound is given below in the section devoted to the chemistry of nitrobenzyl-mercaptan.

(B) The Addition Product of Methyl Iodide and 1,4-Dimethyl-2-*p*-nitrobenzyl-mercapto-6-oxypyrimidine. (II).—The insoluble amorphous compound (B) which was yellowish-brown in color, was observed to turn red slowly on exposure to the air, a behavior which was due evidently to the liberation of iodine. After drying this compound in a vacuum desiccator over sulfuric acid for several days, the weight was found to correspond to 28% of the weight of the total alkylated products. In a repetition of the alkylation with methyl iodide with a quantity of the iodide greater than that previously used, as high as 50% of the insoluble addition compound was obtained in this reaction. This product did not melt sharply; the melting point ranged between 79° and 136°. It gave a very strong test for iodine when treated with sulfuric acid and left no residue when heated on platinum foil. When boiled in 50% alcohol, it was found to dissociate, and the cool solution deposited white needle-like crystals. The compound formed melted at 136° and was identified as 1,4-dimethyl-2-*p*-nitrobenzyl-mercapto-6-oxypyrimidine.

The addition compound was purified by dissolving it to saturation in hot 80% alcohol, filtering off any undissolved material and cooling the solution immediately in an ice-bath, with stirring. By this procedure the compound was obtained in the form of a light brown colloidal precipitate. It was collected and washed with a little 80% alcohol, and dried in a vacuum desiccator over sulfuric acid for several days. Yield, 61%. It melted between 65–75° with slight decomposition.

*Analyses.* Calc. for  $C_{14}H_{16}O_4N_2SI$ : N, 9.69. Found: 9.50, 9.39.

**HYDROLYSIS WITH HYDROCHLORIC ACID.**—From 1 to 5 g. of the addition compound was hydrolyzed by digestion with 50 cc. of conc. hydrochloric acid for several hours. During this operation a yellowish-brown oil separated which solidified immediately when cooled. The yellow solution was then filtered and the residue dried and saved. This compound was identified as *p*-nitrobenzyl disulfide. The yield was nearly quantitative. Two recrystallizations from alcohol gave a product which separated in the form of colorless needles melting at 126° to give a clear yellow oil. A molecular-weight determination was made by the boiling-point method.

*Analyses.* Calc. for  $C_{14}H_{12}O_4N_2S_2$ : N, 8.33; S, 19.05; Mol. wt., 336.0. Found: N, 8.02, 8.34; S, 19.02, 19.09; Mol. wt., 334.5, 346.2.

A further description of this compound and its properties is given in the section dealing with the chemistry of *p*-nitrobenzyl-mercaptan.

The yellow acid filtrate was extracted several times with ether. On evaporating the solvent a crystalline solid was obtained which was identified as free iodine.

When the filtrate from the ether extractions was evaporated to dryness, a grayish-black solid was obtained. The residue was treated with a little cold alcohol to remove traces of iodine, and then recrystallized twice from hot water and decolorized by treatment with Norite. As the solution cooled, the compound separated in the form of white prismatic needles. The melting point, 259–260°, indicated that we were dealing with dimethyluracil.

When the pyrimidine, 1,4-dimethyl-2-*p*-nitrobenzyl-mercapto-6-oxypyrimidine (A) was hydrolyzed with conc. hydrochloric acid to which a little free iodine had been added, the results were similar to those obtained by hydrolysis of the above addition compound. That is, *p*-nitrobenzyl disulfide and 1,4-dimethyluracil were formed in this reaction.

**Synthesis of the Addition Product from its Components.**—To synthesize the addition

compound, methyl iodide (3 moles) was added to a warm alcohol solution of 1,4-dimethyl-2-*p*-nitrobenzyl-mercapto-6-oxypyrimidine and the solution was boiled for 12 hours. As it cooled, yellow needle-like crystals separated. These were found to be free from iodine and after recrystallization from glacial acetic acid, melted at 136°, which corresponds to the melting point of the unaltered mercapto-pyrimidine. After the removal of the methyl alcohol and methyl iodide from the filtrate by distillation, a light brown product was obtained. This gave a very good test for iodine. Digestion with hydrochloric acid transformed it smoothly into *p*-nitrobenzyl disulfide, which melted at 135.5°, and 1,4-dimethyluracil, melting at 260°.

#### Alkylation with Ethyl Bromide.

**2-*p*-Nitrobenzyl-mercapto-4-methyl-6-ethoxy-pyrimidine.** (VIII).—2-*p*-Nitrobenzyl-mercapto-4-methyl-6-oxypyrimidine was added to a sodium ethylate solution made by dissolving a molecular proportion of sodium in absolute alcohol, and the solution was heated for 3 hours. A little more than the molecular quantity of ethyl bromide was then added slowly through a dropping funnel and the solution was heated until it became neutral. The hot solution was filtered to remove sodium bromide, and as the filtrate cooled, rosetts of needle-like crystals separated. After filtering and treating the residue with a little water to remove any traces of sodium bromide, the above pyrimidine was obtained; it melted between 90° and 96°. Recrystallization from alcohol gave a product which melted sharply at 104°. Yield, about 32%.

*Analyses.* Calc. for  $C_{14}H_{15}O_3N_3S$ : N, 13.77. Found: 13.70, 13.90.

**HYDROLYSIS WITH HYDROCHLORIC ACID.**—From 1 to 3 g. of this compound was hydrolyzed by digestion with 100 cc. of conc. hydrochloric acid for 3 hours. The solution was filtered to remove the oil which separated and evaporated to dryness, yielding a yellowish-white solid. This compound was identified as 4-methyluracil. It was obtained in the form of white prismatic needles which crystallized from water and did not melt below 300°. The yield was quantitative.

*Analyses.* Calc. for  $C_5H_6O_2N_2$ : N, 22.22. Found: 22.24, 22.38.

When the oily product formed in this reaction was cooled, it solidified to form a pearl-white solid which corresponded in quantity very closely to the calculated yield for *p*-nitrobenzyl-mercaptan. After recrystallization from alcohol, it was obtained in the form of white transparent plates melting at 57° to give a clear yellow oil. A mixture of this compound with *p*-nitrobenzyl-mercaptan obtained in a previous experiment melted at 57–58°.

#### Alkylation with Allyl Bromide.

**2-*p*-Nitrobenzyl-mercapto-4-methyl-6-allyloxy-pyrimidine.** (IX).—To sodium ethylate solution made by dissolving a molecular proportion of sodium in absolute alcohol, 2-*p*-nitrobenzyl-mercapto-4-methyl-6-oxypyrimidine was added and the solution was heated for 2½ hours. Allyl bromide (1 mol.) was then added slowly through a dropping funnel and the resulting solution was heated until it became neutral. On removal of the alcohol by distillation, a soft, sticky, dark red solid separated. This was dried in a vacuum desiccator over sulfuric acid for several days, and then extracted in a Soxhlet apparatus with dry ether free from alcohol. By this procedure two compounds were obtained; a compound insoluble in ether, which proved on purification to be unaltered material, and a compound soluble in ether.

When ether solution of the soluble compound was evaporated to dryness in the air, a reddish-yellow residue was obtained. After two recrystallizations from ligroin the compound was isolated in the form of light yellow needles which melted at 77–78° to form a clear yellow oil.

*Analyses.* Calc. for  $C_{13}H_{13}O_2N_3S$ : N, 13.25. Found: 13.42, 13.52.

**HYDROLYSIS WITH HYDROCHLORIC ACID.**—A small quantity of this compound was hydrolyzed by digestion with 100 cc. of conc. hydrochloric acid for  $1\frac{1}{2}$  hours. The hot solution was filtered to remove the oil which separated and the filtrate was evaporated to dryness. A nearly quantitative yield of 4-methyluracil was thus obtained which, on recrystallization from water, did not melt below  $300^\circ$ .

By recrystallization of the oily product from alcohol, white transparent plates were obtained which melted at  $57^\circ$  to give a clear yellow oil.

### The Chemistry of *p*-Nitrobenzyl-mercaptan.

When we endeavored to identify *p*-nitrobenzyl mercaptan ( $NO_2C_6H_4CH_2SH$ ), formed in the hydrolysis of some of the 2-mercapto-pyrimidines, unexpected results were obtained. We obtained a product which melted consistently at  $58^\circ$ , while the melting point assigned to this compound in the literature is  $140^\circ$ . This marked discrepancy led us, therefore, to an investigation of the properties of this mercapto compound and its corresponding sulfide derivatives. We found that our product melting at  $58^\circ$  gave analytical results in complete agreement with those required for the mercaptan. When this compound was subjected to oxidation in the presence of iodine, or with potassium permanganate, or air in the presence of ammonia, it was transformed into the disulfide  $(NO_2C_6H_4CH_2)_2S_2$  melting at  $126.5^\circ$ . Price and Twiss<sup>9</sup> give the melting point of this compound as  $126.5^\circ$ . It was prepared by these chemists by the action of sodium carbonate upon *p*-nitrobenzyl thiosulfate.

Strakosch,<sup>10</sup> who investigated the preparation of *p*-nitrobenzyl-mercaptan, prepared it by the action of potassium hydrosulfide and ammonium sulfide upon *p*-nitrobenzyl chloride and states that these reactions lead to the formation of *p*-nitrobenzyl-mercaptan melting at  $140^\circ$ . He also states that, in the case of the action of ammonium sulfide upon *p*-nitrobenzyl chloride, prolonged boiling leads to the formation of *p*-nitrobenzyl disulfide which he describes as melting at  $89^\circ$ . On repeating his work, with potassium hydrosulfide as a reagent, it was impossible to isolate any of the compounds which he describes. Furthermore, it was found that ammonium sulfide reacts with *p*-nitrobenzyl chloride in alcoholic solution to give only the sulfide  $(NO_2C_6H_4CH_2)_2S$  melting at  $158$ – $159^\circ$ .

When *p*-nitrobenzyl chloride was treated with sodium hydrosulfide in alcoholic solution, we obtained two compounds; the disulfide melting at  $126^\circ$ , and the sulfide melting at  $158$ – $159^\circ$ . This compound corresponds to *p*-nitrobenzyl sulfide described by O. Fischer.<sup>11</sup>

The interesting results obtained with *p*-nitrobenzyl-mercaptan raise the question whether the corresponding *ortho* and *meta* isomers of this mercapto compound have been correctly described.

### Summary.

1. Methyl iodide interacts with the sodium salt of 2-*p*-nitrobenzyl-mercapto-4-methyl-6-oxypyrimidine to give first a nitrogen substituted derivative, which then interacts with another molecule of methyl iodide to form an addition product. The methyl group substitutes in the 1-position of the pyrimidine ring.

2. Ethyl bromide and allyl bromide interact with the mercapto-pyrimidine in a manner entirely different from that with methyl iodide. In both of these cases, an oxygen ether is formed, and no evidence was obtained of substitution of the alkyl groups on a nitrogen atom of the pyrimidine ring.

3. In the hydrolysis of 2-*p*-nitrobenzyl-mercapto-pyrimidines with acids, *p*-nitrobenzyl-mercaptan is formed melting at 57–58°. If, however, free iodine functions during hydrolysis, this mercaptan is destroyed and the disulfide, melting at 126.5°, is formed by oxidation.

4. The literature concerning *p*-nitrobenzyl-mercaptan is incorrect; in this paper the melting points of this compound, its disulfide and corresponding monosulfide are described correctly.

## PARA-CYMENE STUDIES. III. THE BROMINATION OF 2-AMINO-PARA-CYMENE.

BY ALVIN S. WHEELER AND IRA W. SMITHEY.<sup>1</sup>

Received August 1, 1921.

The previous two papers dealing with *p*-cymene concerned (1) the production of toluene<sup>2</sup> by the action of aluminum chloride on a mixture of benzene and *p*-cymene and (2) *p*-cymene as a solvent.<sup>3</sup> This paper describes the action of bromine upon 2-amino-*p*-cymene and the preparation of certain derivatives of the monobromo-amino-cymene obtained. The research began with the isolation of cymene from spruce turpentine, a by-product in the manufacture of paper by the sulfite process. In addition to the steps given by one of us in the second paper of this series on the purification of *p*-cymene we find it necessary to shake out the cymene with a limited amount of conc. sulfuric acid. When this is not done the cymene, even though it be a fraction of narrow range in boiling point (176–178°), acquires a yellow color on standing, and fully satisfactory

<sup>1</sup> This paper forms a portion of a thesis submitted by Ira W. Smithey to the faculty of the Graduate School of the University of North Carolina in partial fulfillment of the requirements for the degree of Doctor of Philosophy.

<sup>2</sup> *J. Ind. Eng. Chem.*, 10, 359 (1918).

<sup>3</sup> *THIS JOURNAL*, 42, 1842 (1920).

reactions such as nitration and bromination cannot be carried out with it. Cymene was nitrated by the method of Andrews,<sup>4</sup> modified by the Eastman Kodak Co., who introduce some glacial acetic acid to prevent the product from freezing out. The nitro-cymene was reduced with tin and hydrochloric acid. 2-Amino-*p*-cymene was prepared by Lloyd<sup>5</sup> who heated carvacrol at 350–360° with ammonium bromide and zinc ammonia bromide. Soderbaum and Widman<sup>6</sup> reduced nitrocymene with tin and hydrochloric acid. Goldschmidt<sup>7</sup> treated *isocarvoxime* dissolved in alcohol with zinc dust and acetic acid. Semmler<sup>8</sup> mixed boiling alcoholic solutions of tanacetone-acetoxime and sulfuric acid. Wallach and Schrader<sup>9</sup> heated at 235° carvoxime with conc. aqueous potash. Wallach and Neumann<sup>10</sup> heated *isocarvoxime* with potash at 235°. The method for quantity production is the reduction of nitro-cymene, now that cymene is available in large amounts.

The acetyl derivative of amino-cymene which melts at 71° is smoothly brominated in carbon tetrachloride solution and less satisfactorily in glacial acetic acid solution. Hydrolysis of the brominated product is best effected with conc. hydrochloric acid. The monobromo-amino-cymene thus obtained is a liquid boiling at 169–170° at 20 mm. Its hydrochloride and hydrobromide were prepared.

Considerable effort was made to locate the position of the bromine atom. It did not enter any of the side chains for the product does not possess any properties characteristic of such compounds. The problem was therefore to determine whether it is in Position 3, 5 or 6. The acetyl derivative was oxidized with neutral permanganate and analysis indicated the oxidation of the *isopropyl* group to a carboxyl, forming therefore an acetyl-amino-bromotoluic acid. Hydrolysis gave the hydrochloride of the amino acid and its analysis indicated two acid hydrogens. Finally analysis of the free amino acid agreed with that calculated for a toluic acid. It happens that only one amino-bromotoluic acid is known, the one with bromine at Position 5, melting at 186–187°; whereas our acid melts at 151°. Since an *ortho* compound is far more likely to be formed than a *meta*, we have placed the bromine atoms provisionally at Position 3 and not at 6. We had expected to find it at Position 5. A fuller discussion is reserved for a special part preceding the summary.

Diazo derivatives of amino-bromocymene were prepared by combining it (1) with itself, (2) with aniline and (3) with *p*-nitro-aniline in two

ways, (a) by diazotizing the amino-bromocymene and (b) by diazotizing the *p*-nitro-aniline. The azo derivatives of *p*-nitro-aniline are yellow and dissolve in alkaline solutions, with the formation of a rich magenta color which disappears on acidification. This marked color change indicates a change of structure and is well explained by a shifting of the hydrogen of the imino group to the nitro group, forming a pseudo acid, the alkaline salt having the group:  $\text{NOONa}$ . Thus:  $\text{C}_3\text{H}_7\text{CH}_2\text{BrC}_6\text{H}_2\text{N}:\text{NNHC}_6\text{H}_4\text{NO}_2 \rightarrow \text{C}_3\text{H}_7\text{CH}_2\text{BrC}_6\text{H}_2\text{N}:\text{NN}:\text{C}_6\text{H}_4\text{NOONa}$ . Meldola<sup>11</sup> noticed the same color change with *p*-dinitro-diazo-amino-benzene but he believed that the sodium atom merely replaced the hydrogen of the imino group. Hewitt and Mitchell<sup>12</sup> proposed the better explanation of a pseudo or nitronic acid where the hydrogen of the imino group wanders to the *para* nitro group. A similar change of structure may be assumed in Grandmougin and Leeman's<sup>13</sup> hexanitro-hydrazo-benzene, the dipotassium salt giving a blue solution.

### Experimental Part.

**Nitration of *p*-cymene.**—The method of Andrews was followed, but some modifications were necessary to obtain good yields. The nitration mixture was placed in an iron kettle of about 12 liters capacity, with a wooden lid provided with holes for stirrer, funnel and thermometer. The kettle was surrounded by ice and salt in a wooden tub of 40 liters capacity. An 18 cm. iron stirrer running at 200–250 r. p. m. was used to agitate the mixture. Two kg. of cymene was nitrated at one time. 2010 g. of cymene, b. p. 176–177°, was added slowly with stirring to 2010 g. of conc. sulfuric acid cooled to 0° or below with ice and salt. The mixture was well stirred to insure the formation of a good emulsion. Andrews calls it a solution but this is impossible, for in our experience it requires a week to dissolve cymene in sulfuric acid and then it is undoubtedly sulfonated. To the ice-cold emulsion a mixture of 1500 g. of conc. nitric acid and 3150 g. of conc. sulfuric acid was added from a dropping funnel at the rate of two drops a second, provided cooling by the freezing mixture was efficient. In order to prevent the freezing out of nitrocymene 300 cc. of glacial acetic acid was added to the cymene-acid mixture at the beginning. The operation of nitration required 15 hours. Stirring was continued for 30 minutes after the last of the acid had been added. The product was poured into 6 liters of water containing ice to keep the temperature below 10°. After thorough stirring the nitro-cymene collected on the surface as a red oil. It was separated, washed with water, very dilute sodium hydroxide (conc. alkali causes a troublesome emulsion), and again with water. It was dried with calcium chloride and distilled. The fraction boiling at 148–162° at 35 mm. represented a fairly pure nitro-cymene. Wheeler and Smith are now engaged in preparing a purer nitro-cymene by preliminary treatment with a small amount of bromine.

**Reduction of Nitro-cymene.**—Nitro-cymene was reduced with tin and hydrochloric acid, the process being the same as that used for nitrobenzene. Instead, however, of distilling the alkaline solution with steam, it was found better to add enough sodium hydroxide nearly to dissolve the tin salt and extract with benzene. After drying the solution with solid sodium hydroxide, the benzene was distilled. 350 g.

<sup>11</sup> Meldola, *J. Chem. Soc.*, 49, 626 (1886).

<sup>12</sup> Hewitt and Mitchell, *J. Chem. Soc.*, 91, 1254 (1907).

<sup>13</sup> Grandmougin and Leeman, *Ber.*, 49, 4384 (1906).

of nitro-cymene gave 260 g. of amino-cymene, the calculated yield being 290 g. A fraction boiling a little below and above  $240^{\circ}$  was used for acetylation with acetic anhydride. The pure acetyl derivative melted at  $71^{\circ}$ .

**2-Acetyl-amino-3-bromo-*p*-cymene**,  $C_9H_7CH_2NHCOCH_3BrC_6H_7$ .—One mol. of acetyl-amino-cymene was dissolved in 5 parts of carbon tetrachloride and treated with one mol. of bromine. The temperature rose to  $50$ – $60^{\circ}$  and considerable hydrogen bromide escaped. When the reaction had proceeded for a short time, a mass of white crystals separated from the solution, forming a seemingly solid mass. These crystals were filtered off and recrystallized from alcohol, forming needles which melted at  $122.5^{\circ}$ . The yield was practically quantitative. Bromo-acetyl-amino-cymene is soluble in ether, alcohol, benzene and acetic acid and insoluble in water. Glacial acetic acid may also be used as a solvent for the reaction but unless the temperature is kept down, some bromine will enter the side chains forming compounds which attack the eyes.

*Analyses.* Subs., 0.1818, 0.2614: AgBr, 0.1250, 0.1805. Calc. for  $C_{12}H_{16}ONBr(270)$ : Br, 29.62. Found: 29.26, 29.38.

A sample of crude acetyl-amino-cymene in carbon tetrachloride was boiled with bromine. A small quantity of greenish material separated from solution. It was recrystallized from alcohol and obtained in golden-yellow leaflets which melted at  $188^{\circ}$ .

**2-Amino-3-bromo-*p*-cymene Hydrochloride**,  $C_9H_7CH_2NH_2(HCl)BrC_6H_7$ .—The acetyl derivative above was so little affected by boiling alcoholic potash even after 6 hours, that hydrolysis was effected by boiling with conc. hydrochloric acid for 1 hour. The action could be hastened by decanting at intervals from the undissolved portion, cooling, filtering off the hydrochloride and returning the acid to the flask. The hydrochloride is almost completely insoluble in cold hydrochloric acid, moderately soluble in ether and very soluble in acetone and acetic acid. It dissolves readily in cold water but is hydrolyzed by hot water. It crystallizes from alcohol in silvery hexagonal plates which melt at  $205$ – $210^{\circ}$  with decomposition.

*Analyses.* Subs., 0.2301, 0.2106: AgCl, 0.1306, 0.1176. Calc. for  $C_{10}H_{14}NBr.HCl(264.5)$ : Cl, 13.41. Found: 14.04, 13.81.

**2-Amino-3-bromo-*p*-cymene Hydrobromide**,  $C_9H_7CH_2NH_2(HBr)BrC_6H_7$ .—Pure amino-bromo-cymene was treated with strong hydrobromic acid. A mass of crystals formed instantly. On recrystallizing from alcohol brilliant octagonal plates were obtained which melted at  $200$ – $205^{\circ}$  with decomposition. This salt is hydrolyzed even by cold water. It is fairly soluble in ether, benzene and acetone.

*Analyses.* Subs., 0.4333, 0.5221: AgBr, 0.2653, 0.3199. Calc. for  $C_{10}H_{14}NBr.HBr(309)$ : Br, 25.88. Found: 26.04, 26.07.

**2-Amino-3-bromo-*p*-cymene**,  $C_9H_7CH_2NH_2BrC_6H_7$ .—Pure amino-bromo-cymene hydrochloride is hydrolyzed with 20% sodium hydroxide and the free amine is distilled with steam. A colorless oil appeared in the upper part of the condenser but it rapidly assumed a yellowish color, being distinctly colored when it dropped from the condenser. The aqueous distillate was saturated with salt and extracted with ether. The ether solution was dried with sticks of sodium hydroxide and the ether was distilled. Pure amino-bromo-cymene was driven over at  $169$ – $170^{\circ}$  under a pressure of 20 mm. It is a colorless oil at first but soon becomes yellow and after some time red like aniline. It is very soluble in ether, alcohol and acids and insoluble in water. Its specific gravity, determined by the pycnometer method at  $21^{\circ}$ , is 1.30125. Its refractive index, determined with an Abbe refractometer at  $20^{\circ}$ , is 1.5781.

*Analysis.* Subs., 0.2432: AgBr, 0.2005. Calc. for  $C_{10}H_{14}NBr(228)$ : Br, 35.04. Found: 35.08.

## Diazo Derivatives.

bromo-cymene in 10 cc. of water containing 1.5 cc. of conc. hydrochloric acid, cooled to 0°, was treated with 0.4 g. of sodium nitrite in 5 cc. of water. To this solution was added 1 g. of the amine in 5 cc. of water containing 0.5 cc. of conc. hydrochloric acid. The yellow precipitate which formed was more completely precipitated by the addition of 5 g. of sodium acetate dissolved in 5 cc. of water. The product was recrystallized from petroleum ether from which it separated in yellow prismatic needles which melted at 143–146° with decomposition. Yield, 80%. It is slowly soluble in cold ether, glacial acetic acid, benzene and carbon tetrachloride. It is almost insoluble in cold alcohol.

*Analysis.* Subs., 0.1193: AgBr, 0.0966. Calc. for  $C_{20}H_{25}N_3Br_2$  (467): Br, 34.26. Found: 34.45.

amino-bromo-cymene was treated with 10 cc. of water containing 1.5 g. of conc. hydrochloric acid. The mixture was cooled to 0° and a slight excess of sodium nitrite solution was added. Some of the amine salt still remained undissolved. It was stirred for 15 minutes and then a solution of aniline hydrochloride was added. An orange-red precipitate was formed, the precipitation being furthered by the addition of 5 g. of sodium acetate in 5 cc. of water. The salt which separated was very soluble in hot alcohol, benzene and glacial acetic acid, and was best recrystallized from petroleum ether, from which it formed yellow needles melting at 161–162° with decomposition. The salt was hydrolyzed with dil. sodium hydroxide solution. The free amine crystallized in the form of flat yellow needles which melt at 152–154° with decomposition.

*Analysis.* Subs., 0.0960: AgBr, 0.0538. Calc. for  $C_{18}H_{19}N_3Br$ : Br, 24.09. Found: 23.85.

*p*-Nitrobenzene-diazo-2-amino-3-bromo-*p*-cymene. 0.96 g. of amino-bromo-

cymene hydrochloride was dissolved in 2 cc. of conc. hydrochloric acid and 2 cc. of water. On dilution to 40 cc. much of the salt crystallized. The mixture was cooled to 10° and 0.28 g. of sodium nitrite in 5 cc. of water was added all at once and the mixture stirred for 30 minutes. Five-tenths g. of *p*-nitro-aniline was dissolved in 2 cc. of conc. hydrochloric acid and 2 cc. of water, and diluted to 40 cc. The two solutions were mixed and stirred for 30 minutes. The solution was filtered from slight impurities and treated with sodium acetate, whereupon a yellow precipitate was formed. The diazo compound was recrystallized from alcohol and obtained in the form of bright yellow needles which melted at 158° with blackening.

*Analysis.* Subs., 0.0450: AgBr, 0.0228. Calc. for  $C_{16}H_{17}O_2N_4Br$ : Br, 21.22. Found: 21.56.

This bright yellow compound dissolves in ammonium or sodium hydroxide to form a solution with a rich magenta color, and the color disappears on neutralizing or acidifying the solution. If the neutral colorless solution is warmed, the magenta color comes back, though it is then of less intensity. If the solution is cooled with ice the color disappears again. As suggested in the theoretical part of this paper, the marked change of color must be due to a change of structure, the best supposition being that the salt of a pseudo or nitronic acid has been formed.

On reversing the process by diazotizing the *p*-nitro-aniline an orange colored precipitate was obtained which was purified by recrystallizing from alcohol. The purified product consisted of orange-red needles with a steel-blue fluorescence, melting at  $163^\circ$  with decomposition. It is soluble in alcohol and benzene. It is soluble in conc. hydrochloric acid and does not readily dissolve in cold aqueous sodium hydroxide. The alkaline solution has a magenta-red color like the other nitro derivative. An analysis could not be made on account of lack of material. We believe that in this compound the azo and imino groups have exchanged places:  $C_6H_7CH_2BrC_6H_2NH.N : NC_6H_4NO_2$ .

#### Orientation of the Bromine Atom.

It seems well established that the amino-*p*-cymene is 2-amino-*p*-cymene. Bromination of its acetyl derivative in the cold introduces one bromine atom. It may occupy any one of 7 positions, 3 of which are in the nucleus and 4 in the side chains, *i. e.*, in the methyl, in the amino and 2 places in the *iso*-propyl group. Positions in the side chains are ruled out on account of the fact that the reaction is carried out at a moderate temperature thus indicating entrance into the nucleus and also since the product has no characteristics of the benzyl bromide type. Again, the side chains may be removed or converted into other radicals while the bromine atom remains unaffected.

The question therefore is whether the bromine is at Position 3, 5 or 6. The best hope of locating it seemed to lie in oxidizing the substance to a toluic acid. Oxidation might however produce a cuminic acid or a terephthalic acid. Of the three possible toluic acids, Formulas I, II and III, only II is known. Only one bromo-terephthalic acid having any bearing on the question is known, the 2,6-dibromo derivative, Formula IV. Two of the three possible cuminic acids, Formulas V, VI and VII, are known, those represented by Formulas V and VI.

Fileti and Crosa<sup>14</sup> having oxidized nitro-bromo-cymene with nitric acid to a toluic

<sup>14</sup> Fileti and Crosa, *Gazz. chim. ital.*, 18, 307 (1888).

acid, we tried nitric acid first. Nitric acid (1:2) converted acetyl-amino-bromo-cymene into an amino acid melting at  $196^{\circ}$ , soluble in acids and alkalies, in ether and benzene and very difficultly soluble in water and ligroin. This substance corresponds to none of the toluic or cuminic acids. Neutral permanganate was then tried.

Two g. of acetyl-amino-bromo-cymene and 4 g. of magnesium sulfate were added to 240 cc. of water, warmed to  $80^{\circ}$ , and 6 g. of powdered potassium permanganate was finally added. Heating was continued for an hour and a half. The manganese dioxide was filtered off, the excess of permanganate destroyed with alcohol, and the colorless filtrate acidified with sulfuric acid. The abundant white precipitate crystallized from dil. alcohol in fine needles which melted at  $215^{\circ}$ . The acidity of the product was determined by titration.

*Analysis.* Subs., 0.1013: KOH (0.05 *N* solution used), 0.02085 g.

Required for acid derivatives: Acetyl-amino-bromo toluic acid,  $C_{10}H_{10}O_2NBr$  (mol. wt. 272): 0.02085 g. Acetyl-amino-bromo-cuminic acid,  $C_{12}H_{14}O_2NBr$  (mol. wt.) 300): 0.01890 g. Acetyl-amino-bromo-terephthalic acid,  $C_{10}H_8O_4NBr$  (mol. wt. 302): 0.03753 g.

The product is therefore a toluic acid. It was then hydrolyzed, 0.5 g. being boiled for 30 minutes with 40 cc. of conc. hydrochloric acid. The hydrochloride crystallized in leaf-like crystals which melted at  $190^{\circ}$  with decomposition.

*Analysis.* Subs., 0.1054: KOH, 0.0419 g. Required for 2 acid hydrogens: 0.0427.

The analysis gives indication of a toluic acid. The substance was finally saponified with sodium hydroxide. From the solution acidified with acetic acid a white precipitate separated which turned pinkish after a time. It crystallized from dilute alcohol in yellowish needles which melted at  $151^{\circ}$ .

*Analysis.* Subs., 0.1022: KOH, 0.0247 g. Required for the 3 possible acids: Amino-bromo-toluic acid,  $C_8H_9O_2NBr$  (mol. wt. 230): 0.0248 g. Amino-bromo-cuminic acid,  $C_{10}H_{11}O_2NBr$ , (mol. wt. 258): 0.0221 g. Amino-bromo-terephthalic acid,  $C_8H_7O_4NBr$  (mol. wt. 280): 0.0440 g.

A toluic acid is again indicated. The 3 analyses point to a toluic acid of molecular weight of 272. We had expected to obtain toluic acid II with bromine in Position 5, but the acid melts at  $151^{\circ}$  instead of  $186-187^{\circ}$ . In choosing I instead of III, we are guided by the fact that the bromination of other amino compounds yields *ortho* and *para* compounds and not *meta*. The bromination of 4-amino-*m*-xylene<sup>15</sup> puts bromine *ortho* to the amino group. In this case the *para* place is already occupied. The bromination of 2-amino-*p*-xylene<sup>16</sup> puts bromine *para* to the amino group. Fischer and Windhaus<sup>16</sup> did not however prove it, merely stating that it was "wahrscheinlich." Everything considered we believe that the location of the bromine atom at Position 3 should be regarded as provisional.

### Summary.

1. The nitration of *p*-cymene is described and the reduction of 2-nitro-*p*-cymene.
2. The bromination of 2-amino-*p*-cymene yields the new compound, 2-amino-3-bromo-*p*-cymene. Its acetyl derivative, hydrochloride and hydrobromide are described.
3. Diazo derivatives were prepared, including the coupling of amino-

<sup>15</sup> Noelting, Braun and Thesmar, *Ber.*, 34, 2255 (1901).

<sup>16</sup> Fischer and Windhaus, *ibid.*, 33, 1974 (1900).

bromo-cymene with (1) itself, (2) aniline and (3) *p*-nitro-aniline in two ways.

4. Conversion of the amino-bromo-cymene into a hitherto unknown amino-bromo-toluic acid suggests that the bromine atom occupies Position 3.

5. A new toluic acid, 2-amino-3-bromo-*p*-toluic acid, was prepared; also its hydrochloride and acetyl derivative.

CHAPEL HILL, NORTH CAROLINA.

## SOME COMPOUNDS OF PIPERIDINE WITH HALIDES.

By CLIFFORD S. LEONARD.

Received August 4, 1921.

### I. Inorganic Halides.<sup>1</sup>

A series of new halide compounds may be prepared from piperidine by reaction with halides of trivalent arsenic, antimony, and phosphorus and of tetravalent silicon, tin, and titanium. The solvent used is normal heptane. The complete miscibility of most of the halides employed and of the piperidine with heptane, together with the inert nature of the latter, favor its use. In each case the reaction takes place with as many piperidine molecules as there are halogen atoms available (with the exception of tin chloride, of which two chlorine atoms are inactive).

The reaction appears to be an addition like the formation of ammonium halides from ammonia and hydrogen halides. In general, if *M* is the metalloid, *n* its valence and *X* the halogen, the reaction may be written

The behaviors of the complexes formed are like those of ammonium compounds, *i. e.*, they appear to be piperidinium compounds. We may write the equation and the structural formula in the following way, taking  $AsCl_3$  as the example:<sup>2</sup>

<sup>1</sup> This work comprises part of a thesis presented in June, 1920, to the University of Wisconsin in partial fulfilment of the requirements for the degree of Doctor of Philosophy. See the preliminary note, read by Prof. Edward Kremers before the American Chemical Society, in *Science*, 53, 145 (1920). The formula given in this note is incorrect; a typographical error adds an extra arsenic atom.

<sup>2</sup> Whether the mechanism is direct addition or a substitution followed by addition of freed HCl does not matter as to resultant product. It has been the habit to beg the question of the nature of organic amino-halides; thus aniline and HCl give aniline "hydrochloride." Since this work was completed, Schmidt at the University of Wisconsin has studied similar products from  $AsCl_3$  and aniline. He has named them as substituted aniline hydrochlorides, as is conventional. Obviously their nature must be similar, however, to the compounds here described. (See Schmidt, *This Journal*, 43, 2449 (1921).)

With tetravalent elements such as silicon the fourth halogen carries a fourth imino nitrogen to pentavalence in the same way. These salts may be expected to resemble any known addition products of ammonia itself to the various halides used. Such is borne out by the case of tin tetrachloride. This is described<sup>3</sup> as forming a complex with 2 mols of ammonia instead of 4 as might be expected. The complex with 4 mols is known but is much less stable than the one with 2 mols. So, with piperidine, the complex with tin tetrachloride, which forms even though 4 mols of piperidine are supplied, is the dipiperidyl compound.

If the above is the correct structure, complexes of the following formulas have been studied. (1)  $(\text{C}_6\text{H}_{10}\text{N} \cdot \text{HCl})_3\text{As}$ , which, if named in accordance with the organic "piperidinium" compound described below, is: arsine-tri-1-piperidinium chloride; (2)  $(\text{C}_6\text{H}_{10}\text{N} \cdot \text{HCl})_3\text{Sb}$ , stibine-tri-1-piperidinium chloride; (3)  $(\text{C}_6\text{H}_{10}\text{N} \cdot \text{HCl})_4\text{Si}$ , silicane-tetra-1-piperidinium chloride; (4)  $(\text{C}_6\text{H}_{10}\text{N} \cdot \text{HCl})_2\text{SnCl}_2$ , dichlorostannane-di-1-piperidinium chloride; (5)  $(\text{C}_6\text{H}_{10}\text{N} \cdot \text{HCl})_4\text{Ti}$ , titanane-tetra-1-piperidinium chloride. The phosphorus complex was too unstable for accurate analysis, but qualitative tests show the presence of both phosphorus and chlorine as well as piperidine, and if it is analogous to the arsenic salt it is (6)  $(\text{C}_6\text{H}_{10}\text{N} \cdot \text{HCl})_3\text{P}$ , phosphine-tri-1-piperidinium chloride. It is possible that similar compounds will form with the same readiness from lead tetrachloride, boron trichloride, germanium tetrachloride and vanadium tetrachloride, providing these are soluble in the heptane. These chlorides were not available for the present investigation.

Many halide compounds of piperidine have been prepared but none from these liquid halides of Groups IV and V. The compounds previously made have always been labeled as double salts. The writer believes that those which are made from *piperidine base* and a metallic or non-metallic halide may be likened to ammonium salts and named piperidinium compounds. The simplest would be exact analogs of ammonium chloride; thus, piperidine hydrochloride,  $\text{C}_6\text{H}_{10}\text{NH} \cdot \text{HCl}$ , probably is piperidinium chloride.

Here it may be noted that another type of complex may be formed from these piperidinium salts by further addition, just as double salts may be made from ammonium salts. In the literature this latter type has never been distinguished from the former simpler type. The simpler group will be designated in this paper as Type I, resulting from the combination of piperidine base with metal, metalloid or hydrogen halide. Its prototype

<sup>3</sup> H. Davy, *Schweigger's J. Chem. Physik.*, 10, 321 (1814).

is ammonium chloride,  $\text{NH}_4\text{Cl}$  (Werner's primary compounds). The other group, Type II, is formed from compounds of Type I by addition of another halide. Its prototype is ammonium zinc chloride,  $2\text{NH}_4\text{Cl} \cdot \text{ZnCl}_2$ , ammonium halide double salts (Werner's secondary compounds).

For Type I only the ordinary pentavalence of nitrogen need be invoked while Type II requires extra or subsidiary valences of either nitrogen or halogen to explain its structure. The writer does not intend to go into a discussion here of the valence difference between compounds such as represented by the formulas  $\text{NH}_4\text{Cl}$  and  $2\text{NH}_4\text{Cl} \cdot \text{ZnCl}_2$ . Whatever that is found to be, under Werner's theory or any other theory the same difference will hold between piperidinium salts and piperidinium salt addition compounds.<sup>4</sup>

As an example of Type II may be taken the complex formed from platinous chloride and piperidine hydrochloride and named by Cahours, piperidine chloroplatinate,  $\text{C}_5\text{H}_{10}\text{NH} \cdot \text{HCl} \cdot \text{PtCl}_2$ .<sup>5</sup> If he had taken, as did Williams<sup>6</sup> later, piperidine base and platinous chloride he would have obtained the Type I compound,  $\text{C}_5\text{H}_{10}\text{NH} \cdot \text{PtCl}_2$ . For the sake of brevity a list of piperidine halide compounds in which Type I has been separated from Type II is given at the end of this paper.

The new compounds are of surprisingly high stability. All but the antimony and the phosphorus complexes (the latter was unstable and deliquesced in the air) can be recrystallized from alcohol. The arsenic compound can be recrystallized from water and the hot solution even clarified with bone charcoal. It gives a neutral water solution.<sup>7</sup> The tin and silicon compounds can be recrystallized from alcohol but tend to hydrolyze in the presence of water to form the hydroxides. Addition of dilute alkalis precipitates tin and silicon more completely. The antimony complex is hydrolyzed by 99% alcohol, freeing piperidine hydrochloride.

Confirmation of the belief that these complexes are related to ammonium chloride is afforded by the fact that they themselves further add metal salts as does ammonium chloride. Thus this salt yields with the highly colored lead di-iodide a nearly colorless addition compound (Type II). In an analogous manner the piperidine-arsenic compound has been found to give a crystalline addition complex with lead di-iodide. It reacts similarly with mercuric iodide giving a pale yellow-green compound, which is very different from either yellow or red iodide of mercury. So, too, does arsenious iodide lose its orange color and give a white, crystalline

<sup>4</sup> The newer octet atom-structure theories provide for Type I, *i. e.*, for  $\text{NH}_4\text{Cl}$ . Probably further development of these theories in connection with crystal-structure work will throw light on the Type II structure. See papers by Langmuir and Sir J. J. Thompson.

<sup>7</sup> Conductivity determinations to show the type of ion present would be of interest.

addition product with the piperidine-arsenic compound. The Type I complex adds halides to form products of Type II.

Much difficulty was experienced in the analysis of the new compounds, as might be expected from the presence together of imino nitrogen, chlorine, metalloid, carbon and hydrogen. Arsenic was determined by Ewins' method.<sup>8</sup> Chlorine was determined by the Stephanoff-Bacon<sup>9</sup> method and gave good checked results. Carbon, however, could not be determined by total combustion. Possibly a combustion in the wet way would have succeeded, but a quicker method of analysis was devised as described below.

It was found that the compounds could be hydrolyzed with dilute alkali and the freed piperidine base distilled into standard acid. The acid could be titrated back against standard alkali, and the percentage of piperidine calculated. This method had the further advantage that chlorine could be determined in the distillation residues by simply acidifying with nitric acid and determining by the Volhard method. These latter chlorine determinations checked well with the determinations by the previously cited method. Results checked well in the case of the arsenic compound, so the piperidine and chlorine determinations were considered sufficient to identify the remaining complexes.

The arsenic compound was studied most carefully because of its possible value in medicine. No previously described arsenical compound has been investigated pharmacologically in which the arsenic is bound to the nitrogen of a heterocyclic ring.<sup>10</sup> The findings regarding pharmacological properties of the arsenic compound will be published elsewhere.

### Experimental.

**The Solvent.**—The solvent used in all these experiments was a purified normal heptane obtained from the oil of Jeffery pine. Purification was by the hydrochloric acid method of Sherck;<sup>11</sup> after drying over sodium, the heptane boiled between 97° and 98°. With these very reactive liquid halides the solvent must be dry and free from terpenes or other impurities. Fractions of heptane containing pinene give with arsenic trichloride a brown resin, very slowly precipitated on the wall<sub>15</sub> of the vessel. Even with pure solvent some of the halides react to a slight extent. Clear solutions were obtained with arsenic, silicon, and phosphorus halides. Tin and titanium tetrachlorides gave small amounts of red-brown flocculent pre-

<sup>8</sup> Ewins, *J. Chem. Soc.*, 109, 1356 (1916).

<sup>9</sup> Stephanoff, *Ber.*, 39, 4056 (1906). Bacon, *THIS JOURNAL*, 31, 49 (1909).

<sup>10</sup> One piperidine complex containing arsenic has recently been made by Jacobs and Heidelberger, (*THIS JOURNAL*, 41, 1593 (1919)), N-phenyl-4-arsenic-glycine piperidide, but the piperidine group is not attached to arsenic and the arsenic is in the oxidized form of an arsonic acid.

<sup>11</sup> Sherck, *J. Am. Pharm. Assoc.*, 9, No. 11, 1 (1921).

precipitate from which the clear solution could be decanted. Antimony trichloride (crystalline) reacts immediately with heptane to form a gummy red-brown resin. This tends to coat the crystals and prevent further solution. The antimony trichloride was shaken with solvent for from 12 to 24 hours; then the resin was allowed to settle and the clear solution decanted off.

**General Procedure in the Preparation of the Compounds.**—The halide was weighed out and diluted with solvent to a definite volume. Thus each cubic centimeter contained a known weight of halide. The piperidine was similarly prepared. Piperidine solution was then measured into the reaction vessel which was cooled with ice when a large quantity was employed, and the measured volume of halide solution was slowly poured in with stirring. Immediate precipitation occurred. Stirring was continued for some time, then the solution was allowed to stand and was warmed to room temperature. Refluxing at the boiling point of the heptane was not found to change the character of the material. As the precipitates were very voluminous and held much heptane either by capillarity or by adsorption, the reaction mass was usually a light yellow or white mud. The material was filtered and pressed. The precipitates were found to dry thoroughly with little decomposition on standing in the air. Final drying before analysis was in a desiccator over calcium chloride. No hydrochloric acid is given off at any stage of the preparation, which is evidence in itself that the reaction is an addition. The piperidine was commercial material. The halides were the purest obtainable reagents.

**Arsenic Compound,  $(C_6H_{10}N.HCl)_3As$ .**—By the above method arsenic trichloride was combined with piperidine. Preliminary experiments showed that the same white compound formed whether 1, 2 or 3 mols of piperidine were present, only in different amount. In the single case of this arsenic complex the heptane holds about  $\frac{1}{3}$  of the material in solution. This could be precipitated by adding an equal volume of ether. The total yield then approximated that calculated. The arsenic compound could be recrystallized from alcohol in long needles, nearly pure white in color, melting at  $238^\circ$ .

The compound was very soluble in water (about 1:1). On evaporating a water solution to dryness, no change of weight of arsenic compound was found to have occurred. Consequently the material was crystallized from water thereafter. Long heating in water caused the solution to darken in color. Such solutions could be boiled with bone charcoal, then filtered and would come through light yellow in color. In this way excellent crops were obtained, melting at  $240^\circ$ . Whether recrystallization was from alcohol or water, on redissolving the substance after air drying, small amounts of white, insoluble material were always present. Possibly, therefore, there is a slight hydrolysis or oxidation of the complex in the air.

The arsenic compound was soluble in chloroform, pyridine and carbon disulfide; somewhat soluble in heptane, insoluble in ether, petroleum ether, acetone and carbon tetrachloride.

Piperidine was determined by the distillation method described above. A Volhard chlorine determination was run on the distillation residue. Ewins' iodometric method was used for arsenic.

*Analyses.* Calc. for  $(C_5H_{10}N.HCl)_3As$ : piperidine, 58.4; Cl, 24.35; As, 17.20. Found: piperidine, 62.1; Cl, 24.78; As, 13.09; total, 99.97.

This was further checked by Dumas nitrogen determinations and by chlorine determinations by the Stephanoff-Bacon method. Although total combustions were not successful in determination of carbon, the water, and consequently the hydrogen from these checked well, and averaged very close to the calculated results. When carbon is calculated from the piperidine figure above and the other percentages are all taken from direct determinations, the following are the results.

*Analyses.* Calc.: C, 41.16; H, 7.67; N, 9.62; Cl, 24.35; As, 17.20. Found: C (from piperidine), 43.8; H (comb.), 7.92; N (Dumas), 11.17; Cl (Bacon), 24.78; As (Ewins), 13.09; total, 100.76.

Piperidine results are a little higher than the calculated and arsenic low by about the same amount.<sup>12</sup>

*Addition reactions* of the arsenic compound. Just as ammonium chloride and lead di-iodide give a white, crystalline addition product,<sup>13</sup> so the arsenic compound and colored halides react. *With lead iodide.* One g. of orange-yellow lead di-iodide was triturated with 2 g. of the arsenic compound and with 1 cc. of water. The reaction did not go to completion until the mixture was heated to boiling, but then the solution had a faint yellow color, and pale yellow needle crystals of a complex formed on cooling. The solution could be diluted to 15 cc. without decomposition and with the same crystals re-appearing after each heating and cooling. *With mercuric iodide.* One g. of red mercuric iodide was similarly triturated with the arsenic compound and on boiling gave a green solution. When cooled, pale yellow-green needle crystals formed of different color from crystals of yellow mercuric iodide. The solution could be diluted to about 5 cc. without change, but beyond this dilution red mercuric iodide precipitated and on heating, collected as yellow liquid on the bottom, solidifying as yellow mercuric iodide on cooling, and gradually changing to the red form. *With arsenic iodide.* One g. of arsenic tri-iodide was similarly triturated with the arsenic compound and while a clear solution was not obtained as in the previous cases, on heating to boiling, then cooling, rose colored to white crystals formed above the permanent precipitate (the latter probably from impurities in the tri-iodide used). On dilution to 5 cc. this white complex continued to come out on cooling after short boiling. With great dilution it did not appear, but the deep orange color of arsenic tri-iodide did not reappear.

The arsine-tri-1-piperidinium chloride does not give a precipitate with the general alkaloidal reagents except with phosphomolybdic acid, when the precipitate is of light yellow color.

*Antimony Compound,  $(C_5H_{10}N.HCl)_3Sb$ .*—Antimony trichloride dissolved in heptane (see difficulty under "solvent") was added to piperidine solution in the ratio of one mol to three. The white solid which precipitated had a melting point of 235° after air-drying. The white precipitate was recrystallized from 99% alcohol. The recrystallized product, however, analyzed not as the antimony complex expected but as piperidine hydrochloride with just enough antimony to give a qualitative test.

*Analyses.* (Recrystallized material). Calc. for  $(C_5H_{10}N.HCl)_3Sb$ : piperidine, 52.99; Cl, 22.07. Calc. for  $C_5H_{10}N.HCl_3$ : piperidine, 70.06; Cl, 29.1. Found: piperidine, 68.14; Cl, 29.47.

On analysis, the unrecrystallized material was found to approach the formula which had been expected.

<sup>12</sup> Schmidt (Ref. 2) discards Ewins' method for arsenic, as giving low results for the aniline-arsenic-chloride compound.

<sup>13</sup> "U. S. Pharmacopeia," VIII, p. 309 (1890).

Calc. for  $(C_5H_{10}N.HCl)_3Sb$ : piperidine, 52.99; Cl, 22.07. Found: piperidine, 49.81; Cl, 21.85.

**Silicon compound**,  $(C_5H_{10}N.HCl)_4Si$ .—This was prepared in the same manner as the arsenic compound but using 4 mols of piperidine to each mol of silicon tetrachloride. The melting point of the product recrystallized from 99% alcohol was  $238^\circ$ . The substance was also soluble in chloroform. A small amount of flocculent precipitate filtered from the alcohol solution, was dried and found to be wholly inorganic. Probably the percentage of water in the alcohol hydrolyzed a little of the compound to silicic acid. Possibly it may have come from oxychloride in the reagent, however.

*Analyses.* Calc. for  $(C_5H_{10}N.HCl)_4Si$ : piperidine, 66.66; Cl, 27.78. Found: piperidine, 65.97; Cl, 28.18.

**Tin Compound**,  $(C_5H_{10}N.HCl)_2SnCl_2$ .—Prepared by the general method from 4 mols of piperidine and 1 mol of tin tetrachloride. The white precipitate was recrystallized from alcohol, and melted at  $201^\circ$ . (On adding more stannic chloride to the heptane mother liquor a further precipitate of the material was obtained, indicating the presence of excess of piperidine). The tin compound did not analyze for  $(C_5H_{10}N.HCl)_4Sn$  as had been expected in analogy with the arsenic and silicon compounds. It was found to approximate to  $(C_5H_{10}N.HCl)_2SnCl_2$ .

*Analyses.* Calc. for  $(C_5H_{10}N.HCl)_4Sn$ : piperidine, 56.64; Cl, 23.6. Calc. for  $(C_5H_{10}N.HCl)_2SnCl_2$ : piperidine, 39.54; Cl, 32.91. Found: piperidine, 36.51; Cl, 36.17.

Chlorine is thus present in greater amount, and piperidine in less amount, than calculated for the di-piperidyl compound.

**Titanium compound**,  $(C_5H_{10}N.HCl)_4Ti$  (?).—Only a small amount of titanium tetrachloride was available for this work. On mixing 1 mol with 4 mols of piperidine in heptane a leaf-green precipitate formed. This was filtered on a Büchner funnel but began to lose color as it dried. Within a few minutes it had become white. The melting point was  $238-240^\circ$ . On analysis of the unrecrystallized product, the result for piperidine was found to be quite low for the formula  $(C_5H_{10}N.HCl)_4Ti$ , and nearer in fact to that for  $(C_5H_{10}N.HCl)_2TiCl_2$ . However, the chlorine result was nearer that calculated for the first formula and much lower than for either dipiperidyl or tri-piperidyl complexes.

*Analyses.* Calc. for  $(C_5H_{10}N.HCl)_4Ti$ : piperidine, 64.21; Cl, 26.73. Calc. for  $(C_5H_{10}N.HCl)_2TiCl_2$ : piperidine, 47.38; Cl, 39.37. Found: piperidine, 51.68; Cl, 24.83.

Probably the unrecrystallized material as analyzed was more or less a mixture, but more titanium tetrachloride was not available, so that this could not be determined.

**Phosphorus compound**,  $(C_5H_{10}N.HCl)_3P$  (?).—Phosphorus trichloride was found to give a white precipitate with 3 mols of piperidine. No hydrogen chloride came off in this reaction. The precipitate on filtering was found to be very susceptible to the moisture of the air, turning yellow and gummy. It was dried in a vacuum desiccator but had then deteriorated too much for analysis. Qualitative tests showed the presence of both phosphorus and chlorine. If the analogy with the other compounds holds the formula should be  $(C_5H_{10}N.HCl)_3P$ . Michaelis and Luxembourg<sup>14</sup> prepared in ether solution a substance of the formula  $(C_5H_{10}N)_3P$ , but this was by precipitating in the presence of a large excess of piperidine. Probably the addition of 3 mols' excess of piperidine would convert the hydrochloride into the free phosphine by virtue of the stronger basicity of piperidine. The phosphorus compound may be worthy of further investigation.

<sup>14</sup> Michaelis and Luxembourg, *Ber.*, 28, 2207 (1895).

II. 1-( $\alpha$ -methylamyl)piperidinium-iodide.

It was thought that piperidine should give addition compounds similar to those with inorganic halides described above, by reaction with organic halides of longer chain than the simpler carbon halides, carbon tetrabromide, and acetylene iodide, etc., which Dehn<sup>15</sup> had investigated.  $\alpha$ -Methylamyl-iodide, being at hand, was tried.

The halide freshly distilled was mixed with a heptane solution containing one mol of piperidine. The mixture was refluxed for one hour. White crystals began to appear at the edge of the liquid and later a red oil was seen on the bottom. On cooling the mixture and shaking, the red oil crystallized to yellow needles. These were filtered out and dried. The yield was about  $1/3$  that calculated for the monopiperidyl complex. The mother liquor was distilled and could be separated into a fraction containing heptane and piperidine, and a fraction containing  $\alpha$ -methylamyl iodide. On remixing these and after standing, more of the yellow crystals appeared. Possibly, therefore, longer refluxing would have increased the original yield. The  $\alpha$ -methylamyl iodide compound was very soluble in alcohol and in water. The melting point was unchanged after recrystallization with alcohol, 133°. The substance was also soluble in chloroform and slightly soluble in ether, insoluble in heptane, carbon tetrachloride or carbon disulfide.

Analysis by the piperidine distillation method described in the previous paper showed it to be a substance of the formula  $(C_5H_{10}N.HI)C_6H_{12}$ .

Analyses. Calc.: piperidine, 28.18; I, 42.71. Found: piperidine, 29.01; I, 43.15.

If the structure of this compound is to be explained on the same basis as that of the metalloid compounds, it is a *sec*-hexyl-piperidonium iodide  $(C_5H_{10}N(HI)-CH(CH_3).CH_2CH_2CH_2CH_3)$ . This reaction opens up possibilities in the coupling of organic halides and organic bases in heptane solution. If other aliphatic monohalides give similar addition products with piperidine, and these have sharply defined melting points, these may be useful in identification of the different aliphatic halides. There are further possibilities of preparation of various organic compounds from these piperidinium halides, for instance, by replacement of the halogen. The results of Grignard reactions might be interesting if this treatment were found not to decompose the original complex.

## Summary.

A series of new addition compounds of piperidine with halides of elements of the fourth and fifth group of the periodic system have been prepared. They comprise substances of the following formulas:  $(C_5H_{10}N.HCl)_3As$ ,  $(C_5H_{10}N.HCl)_3Sb$ ,  $(C_5H_{10}N.HCl)_4Si$ ,  $(C_5H_{10}N.HCl)_2SnCl_2$ , and titanium and phosphorus compounds which are probably of similar structure.

Reasons are advanced for assigning to these the structure of piperidinium chlorides, and known piperidine addition compounds are assigned to two groups, according to whether they are (Type I) compounds of piperidine free base and a halide or acid or salt, or (Type II) compounds of piperidine hydrohalides with halides.<sup>16</sup>

<sup>15</sup> Dehn, THIS JOURNAL, 34, 286 (1913); 33, 1588 (1912).

<sup>16</sup> Piperidine addition compounds. ### TETRAPROPYL-ETHANE.

BY JEAN PICCARD AND RAY Q. BREWSTER.<sup>1</sup>

Received August 9, 1921.

The number of heavier hydrocarbons with side-chained structures described in the literature is very small. Yet these hydrocarbons are of interest not only to the physical chemist in view of their surface tension and other constants, but also to the organic chemist for the identification of the carbon skeleton of unknown compounds. While in recent years many new methods have been found for the determination of characteristic groups in organic molecules, practically no progress has been made toward the determination of the carbon skeleton since Baeyer's distillation with zinc dust and its famous application to the identification of alizarin. So many good reducing agents have been found in the last few years, however, that it should be possible in most cases to reduce, in well defined successive steps, any organic compound to the corresponding saturated hydrocarbon.

Several years ago Baeyer and Piccard,<sup>2</sup> while working on dimethylpyrone, discovered an interesting violet dye of unknown constitution. The identification of its carbon skeleton was attempted by the oxidation methods in general use. A considerable number of new derivatives were thereby obtained without any progress toward the solution of the problem, since all the oxidation products obtained were unknown.

The problem was later attacked by Piccard and Edmond Wallach and still later by Piccard and McLauren, who applied successively different reduction methods with the purpose of obtaining a saturated hydrocarbon. Unfortunately this work was twice interrupted by the military obligations of the collaborators. Since there are reasons for believing that the hydrocarbon which would result from complete reduction of the violet dye would be symmetrical tetrapropyl-ethane, and since this hydrocarbon is not yet described in the chemical literature, the present work was begun parallel to the work of our collaborators Wallach and McLauren, with the

<sup>1</sup> The material presented here is used by Ray Q. Brewster in his dissertation presented in partial fulfillment of the requirements for the degree of Doctor of Philosophy in the University of Chicago.

<sup>2</sup> Baeyer and Piccards, *Ann.*, **384**, 208 (1911); **408**, 332 (1915).

purpose of synthesizing the new hydrocarbon by the Wurtz reaction. Since the reduction of the violet dye has thus been indefinitely delayed this synthesis of tetrapropyl-ethane is now published separately.

### The Synthesis of Sym. Tetrapropyl-ethane.

The plan of the work was as follows. Butyrene (A) obtained by the dry distillation of calcium butyrate, was reduced by means of metallic sodium and a little water, forming as the chief product  $\delta$ -oxyheptane (B) and a smaller quantity of the pinacone, tetrapropyl-glycol (C). The  $\delta$ -oxyheptane (dipropyl-carbinol) was transformed into its iodide<sup>3</sup> (D) which, when boiled with sodium in ether solution, gave the desired hydrocarbon, tetrapropyl-ethane, (E). However, the fact that the Wurtz reaction is sometimes liable to proceed with rearrangements led us to look for another method for the synthesis of the tetrapropyl-ethane. For this purpose the reduction of the symmetrical tetrapropyl-glycol was selected.

The reduction of the pinacone was a difficult piece of work but there was finally obtained a pure hydrocarbon in quantities sufficient for comparison with the hydrocarbon first prepared from the  $\delta$ -heptyl iodide. Both compounds were found to be identical. Hence the new tetradecane is the desired *sym.* tetrapropyl-ethane or bis- $\delta$ -heptyl.

### Experimental Part.

Butyrene was prepared by the distillation of calcium butyrate. In the first experiments the calcium butyrate, in 200 to 300g. lots, was distilled from a large copper tube heated in a combustion furnace. However, there was some difficulty with the tube becoming clogged; and the yield of the butyrene was not so large as when the calcium butyrate was distilled in smaller portions. This observation is in agreement with the experiments of Chancel.<sup>4</sup>

In the method finally adopted the calcium butyrate was distilled from a 500cc. copper flask in portions of 50 g. each. Before beginning the operation the air was swept out of the flask by a stream of carbon dioxide. The carbon dioxide was then shut off and the flask heated with the full heat of one Bunsen burner. At the end of the process the volatile products remaining in the flask were carried over into the condenser by a stream of carbon dioxide. The average yield was about 26 cc. of crude butyrene

<sup>3</sup> Friedel, *Jahresber.*, 1869, 514.

Kurtz, *Ann.*, 161, 214 (1872).

<sup>4</sup> Chancel, *Ann.*, 52, 295 (1844).

with 2.5-3.0 cc. of water. The time used for the complete operation was about 25 minutes.

The crude butyrone (465 cc.) was subjected to a steam distillation, dried and fractionated. The fraction boiling at 140-146° was collected. Yield, 200, g. The moistened butyrone was reduced to dipropyl-carbinol and tetrapropyl-glycol by means of metallic sodium.<sup>5</sup> In order to increase the relative yield of the pinacone the butyrone was diluted with as little ether as possible. From 120 g. of butyrone there was obtained 84 g. of  $\delta$ -oxyheptane and 23.5 g. of the tetrapropyl-glycol, boiling at 150° and 260° respectively. The latter solidified in the receiver, and after recrystallization from ether melted at 68°.

$\delta$ -Heptyl iodide,  $(\text{CH}_3\text{CH}_2\text{CH}_2)_2\text{CHI}$ .—Fifty g. of  $\delta$ -oxyheptane (dipropyl-carbinol) was mixed with 10 g. of red phosphorus and to this was added 60 g. of iodine in small portions. After 3 hours the reaction product was washed with dil. sodium hydroxide solution, dried and distilled. It passed over with partial decomposition at 180-185°. Distillation under reduced pressure gave the heptyl iodide in almost colorless form. It distills at 65-67° under 9 mm. pressure with only very slight decomposition.<sup>6</sup>

*Analyses.* Subs., 0.1322, 0.2245: AgI, 0.1363, 0.2323. Calc. for  $\text{C}_7\text{H}_{15}\text{I}$ : I, 56.19. Found: 55.73, 55.93.

*Sym. Tetrapropyl-ethane*,  $(\text{CH}_3\text{CH}_2\text{CH}_2)_2\text{CHCH}(\text{CH}_2\text{CH}_2\text{CH}_3)_2$ .—For the preparation of symmetrical tetrapropyl-ethane by the Wurtz reaction, 58 g. of  $\delta$ -heptyl iodide was dissolved in 150 cc. of absolute ether. Twenty g. of sodium wire was added and the solution was boiled for 20 hours. The ether solution was then separated from the sodium iodide and unchanged sodium, washed with water and dried. After removal of the ether the remaining oil was fractionated. The first portion of the distillate consisted of 8 cc. of a hydrocarbon boiling at 98-100° which undoubtedly was *n*-heptane. The main fraction distilled at 215-225° and was considered to be the desired tetrapropyl-ethane. After purification with conc. sulfuric acid and redistillation the product gave the boiling points 220° at 760 mm. and 105-106° at 12 mm. It was halogen-free (copper oxide test), and the pink coloration produced by a trace of iodine showed that it was also free from oxygen. The liquid is remarkably thin for a hydrocarbon of such a high molecular weight. This low viscosity is due to the fact that the molecule contains two side chains. On cooling with solid carbon dioxide and ether the oil became extremely viscous but did not crystallize.

The combustion was made in an atmosphere of nitrogen.

*Analyses.* Subs., 0.1200, 0.1383:  $\text{CO}_2$ , 0.3730, 0.4297;  $\text{H}_2\text{O}$ , 0.1630, 0.1912. Calc. for  $\text{C}_{14}\text{H}_{30}$ : C, 84.75; H, 15.25. Found: C, 84.77, 84.74; H, 15.20, 15.47.

The molecular weight was measured by the freezing-point method in benzene solution.

*Analyses.* Wt. of benzene, 16.22 g. Subs., 0.0812, 0.1984, 0.3367: depression, 0.129°, 0.327°, 0.539°. Mol. wt., calc.: 198. Found: 198.6, 187.5, 192.5; mean, 193.

Measurements of the density, the surface tension and the index of refraction were also made. These constants will be given together with the constants of the hydrocarbon prepared from tetrapropyl-glycol.

#### Preparation of Tetrapropyl-ethane from Tetrapropyl-glycol.

Three g. of tetrapropyl-glycol was reduced to the parent hydrocarbon by being heated at 180° in a sealed tube with 15 cc. of conc. hydriodic acid for 10 hours. The

<sup>5</sup> Kurtz, Ref. 3.

<sup>6</sup> Kurtz, Ref. 3, did not obtain the iodide in pure condition. He reported only 47.72% of iodine in his product.

reaction mixture of 6 combined lots was treated with sodium hydroxide and the remaining oil taken up with ether. The ether solution was washed with water and dried. After removal of the ether the main fraction distilled at 210–230°. The formation of free iodine and hydriodic acid showed that the product still contained some iodide. Another treatment with hydriodic acid removed all but traces of iodine. This last small amount was removed with zinc dust, acetic acid and alcohol.<sup>7</sup> The product thus obtained was halogen-free but with iodine it gave a brown color indicating the presence of an oxygen-containing compound. For the removal of this the oil was shaken with pure conc. sulfuric acid, separated and distilled over sodium. There was then obtained about 7 cc. of pure hydrocarbon which boiled at 220°. It gave a pink color with iodine and did not decolorize a very dilute solution of potassium permanganate. At a pressure of about 12 mm. of mercury it boiled at 107°. The hydrocarbon is a very thin liquid, which on cooling with solid carbon dioxide and ether became quite viscous but did not crystallize.

*Analyses.* Subs., 0.1187, 0.1502: CO<sub>2</sub>, 0.3690, 0.4680; H<sub>2</sub>O, 0.1610, 0.2045. Calc. for C<sub>14</sub>H<sub>30</sub>: C, 84.75; H, 15.25. Found: C, 84.79, 84.98; H, 15.18, 15.24.

The molecular weight was measured by the freezing-point method in benzene solution.

*Analyses.* Wt. of benzene, 16.27 g. Subs., 0.0944, 0.2137, 0.3919: depression, 0.149°, 0.333°, 0.617°. Mol. wt., calc.: 198. Found: 194, 197, 195; mean, 195.

The physical constants were measured under the same conditions under which they had been measured for the hydrocarbon prepared by the Wurtz reaction. The following table shows the identity of both hydrocarbons. The slight differences may be accounted for by traces of impurities that might be produced in either process. We assume that the hydrocarbon produced by the Wurtz reaction is the purer.

	Prepared by the	
	Wurtz Reaction.	Reduction of Pinacone.
B. p. at atm. pressure.....	220°	220°
B. p. at 12 mm.....	105–106°	107°
Density, 25°.....	0.7785	0.7749
Surface tension (measured with a Traube stalagmometer).....	25.64	25.31 dynes/cm.
Index of refraction (Abbe refractometer) at 25°.....	1.4322	1.4335
Consistency at room temperature....	very liquid	very liquid
Consistency at –80°.....	very viscous	very viscous.

### Summary.

Sym. tetrapropyl-ethane has been prepared by two synthetic methods and its physical properties measured. These data will be of value in further work on the reduction products of dimethyl-pyrone.

## THE THREE AMINO-TRIPHENYLAMINES.

BY JEAN PICCARD AND RAY Q. BREWSTER.<sup>1</sup>

Received August 9, 1921.

The three mononitro-triphenylamines are known. The *para* compound has been prepared by Richard Herz,<sup>2</sup> while the *o*- and the *m*-nitro-triphenyl amines were obtained by Piccard and Larsen.<sup>3</sup> Up to the present only the *para* compound has been reduced to the corresponding amino derivative.<sup>4</sup> Believing that the description of a nitro compound was not complete without the description of the corresponding amine and its acetyl derivative, the reduction of the nitro-triphenylamines newly prepared by Piccard and Larsen was undertaken. The reduction was carried out by Gambarjan's method with zinc dust in a solution of acetic acid and alcohol but the nitro compound was added very gradually to the reducing agent. In this way one avoids having simultaneously the nitro compound and an amino compound in the same solution. These two compounds are often able to react with the formation of disagreeable by-products.

### Experimental Part.

***m*-Amino-triphenylamine Hydrochloride.**—A solution of 1.9 g. of *m*-nitro-triphenylamine in 20 cc. of glacial acetic acid was added during the course of 10 to 15 minutes to a mixture of 8 g. of zinc dust, 6 cc. of absolute alcohol and 6 cc. of glacial acetic acid. Heat was evolved at each addition and the red color of the nitro compound faded rapidly. The liquid was filtered from the excess of zinc at the pump and washed with hot glacial acetic acid. Care was taken to draw as little air as possible through the zinc. The filtrate was made alkaline with a dilute solution of sodium hydroxide, and the precipitated base was removed by filtration, dissolved in ether and dried. Saturation of the ether solution with dry hydrogen chloride precipitated the hydrochloride of the *m*-amino-triphenylamine; yield, 1.9 g. This was dissolved in 400 cc. of hot water to which 15 cc. of conc. hydrochloric acid had been added. The solution was then decolorized with charcoal and cooled in a freezing mixture. About 1 g. of the hydrochloride crystallized in glistening colorless plates. An additional quantity (0.5 g.) could be precipitated out of the mother liquor by hydrogen chloride.

**Analyses.** Subs., 0.1374: 4.70 cc. of 0.1 *N* NaOH (methyl orange). Subs. 0.2287: AgCl, 0.1081.

<sup>1</sup> The material presented here is used by Ray Q. Brewster in his dissertation presented in partial fulfilment of the requirements for the degree of Doctor of Philosophy in the University of Chicago (1919).

<sup>2</sup> Herz, *Ber.*, 23, 2537 (1890).

<sup>3</sup> Piccard and Larsen, *THIS JOURNAL*, 39, 2006 (1917).

<sup>4</sup> Herz, Ref. 2, was the first to prepare *p*-amino-triphenylamine although he published only a rough analysis of the hydrochloride and the acetyl derivative. Haussermann, *Ber.*, 39, 2763 (1906), isolated the base itself in a pure and stable form and published a good nitrogen determination. This work must have been overlooked by Gambarjan, *ibid.*, 41, 3507 (1908), who published a new description and analysis.

Calc. for  $C_{18}H_{17}N_2Cl$ : Cl, 11.96. Found: 12.12, 11.69.

The hydrochloride is very slightly soluble in water.

*m*-Amino-triphenylamine.—The *m*-amino-triphenylamine was precipitated from the aqueous solution of its hydrochloride by the addition of ammonium hydroxide. The base was dissolved in 95% ethyl alcohol, boiled with charcoal, filtered and allowed to crystallize. The substance was thus obtained in nearly colorless form, m. p.  $116^\circ$ . It is readily soluble in alcohol, ether and benzene.

*Analyses.* Subs., 0.1800, 0.1837: dry  $N_2$ , 17.0 cc. ( $15^\circ$  and 739 mm.), 17.6 cc. ( $19^\circ$  and 743 mm.). Calc. for  $C_{18}H_{15}N_2$ : N, 10.77. Found: 10.88, 10.94.

*m*-Acetyl-amino-triphenylamine.—One g. of the *m*-amino-triphenylamine was boiled for 15 minutes with 10 cc. of acetyl chloride. Water was added and the precipitated acetyl derivative recrystallized from alcohol, m. p.  $167^\circ$ .

*Analyses.* Subs., 0.1323:  $CO_2$ , 0.3865;  $H_2O$ , 0.0698. Calc. for  $C_{20}H_{15}ON_2$ : C, 79.49; H, 5.96. Found: C, 79.68, H, 5.94.

*o*-Amino-triphenylamine.—The *o*-nitro-triphenylamine was reduced in the manner just described for the *meta* compound. The crude yield was practically the calculated quantity. After recrystallization from alcohol the base was obtained in thin plates which had only a slight pink tint, and melted at  $145^\circ$ . It is readily soluble in alcohol and benzene but only fairly soluble in ether or ligroin.

*Analysis.* Subs., 0.1878: dry  $N_2$ , 17.7 cc. ( $16^\circ$  and 740 mm.). Calc. for  $C_{18}H_{15}N_2$ : N, 10.77. Found: 10.84.

*o*-Acetyl-amino-triphenylamine.—This compound was prepared in the same manner as the corresponding *meta* derivative. It is quite readily soluble in ether, alcohol and benzene, but only fairly soluble in ligroin; m. p.  $130^\circ$ .

*Analyses.* Subs., 0.1340:  $CO_2$ , 0.3905;  $H_2O$ , 0.0725. Calc. for  $C_{20}H_{15}ON_2$ : C, 79.49; H, 5.96. Found: C, 79.37; H, 6.10.

### Reduction of Nitro-triphenylamines in Concentrated Sulfuric Acid Solution.

L. Gattermann<sup>5</sup> has obtained *p*-aminophenol by the electrolytic reduction of nitrobenzene in conc. sulfuric acid solution. The same author has applied this method for the reduction of many other nitro compounds. Piccard and Larsen used it for the reduction of *m*-nitro-diphenylamine. It is surprising, that *m*-nitro-triphenylamine and *o*-nitro-triphenylamine cannot be reduced by this method to the corresponding *p*-oxy derivatives. We obtained in both cases only high molecular compounds with a lower nitrogen content than the one calculated for the diphenylamino-*p*-aminophenols.

### Summary.

1. The *o*- and *m*-amino triphenylamines have been prepared and characterized. Since the *para* derivative is already known the series is now complete.

2. Attempts to reduce the nitro-triphenylamines to their corresponding amino phenols met with no success.

## UNIFORMITY IN INVERTASE ACTION.

BY J. M. NELSON AND DAVID I. HITCHCOCK.

Received August 13, 1921.

## I. Introduction.

The study of the nature of enzymes has developed chiefly along two distinct lines. So far all attempts to isolate an enzyme as a pure substance of definite chemical composition have been without satisfactory results. Accordingly considerable work has been done to gain an insight into the nature of the enzyme itself by studying the velocity of the reaction which is catalyzed by the enzyme. The object in all these researches on the chemical kinetics of enzyme action has been to find some general law governing the rate of the reaction, and by means of this to make deductions concerning the mechanism of the action and the nature of the enzyme.

In all such work the tacit assumption has been made that any two preparations of the same enzyme, if the same amount of active enzyme is present, and other conditions are the same, will catalyze the reaction at identical rates at corresponding points throughout. In other words, if the course of the reaction were plotted, the two curves should be superimposable. While this assumption has not been definitely stated in the past, it is a necessary implication of the attempt to find a general law for the rate of the catalyzed reaction. Accordingly it seemed desirable, before going further in the attempt to obtain a general law for the hydrolysis of cane sugar by the catalytic action of invertase, to find out by direct experiment whether several different enzyme preparations would really give the same quantitative course to the reaction.

## II. Differences in Invertase Action.

In order to make this comparison, it was necessary to have all the conditions alike except for the use of different invertase preparations. The conditions adopted were a temperature of 25°, an initial sucrose concentration of 10 g. per 100 cc., and a hydrogen-ion concentration of  $10^{-4.4}$  to  $10^{-4.5}$  secured by 0.01 *M* buffer solution of acetic acid and sodium acetate. The amounts of invertase were so adjusted in each experiment that the reaction started off at the same rate. This was accomplished by a few preliminary experiments, making use of the fact noted by Nelson and Vosburgh,<sup>1</sup> that the velocity of inversion is directly proportional to the concentration of the enzyme. The extent of inversion was determined by the polariscopic method. That this method is justifiable has been established by Vosburgh<sup>2</sup>.

<sup>1</sup> Nelson and Vosburgh, *THIS JOURNAL*, 39, 790 (1917).

<sup>2</sup> Vosburgh, *ibid.*, 43, 219 (1921).

Table I contains the results of 10 experiments with 4 different invertase preparations. These preparations were all obtained from yeast by modifications of the method of Nelson and Born. No differences in the method of preparation are known which might account for the abnormality of No. 3. Further description of the method of preparation will be found under the heading "Experimental Details."

2 to 4 days	16.85	16.85	16.85	16.85	16.85	16.85	....	

<sup>a</sup> The high values of these figures are due to the fact that invertase No. 2 itself had an unusually high rotation.

It will be noticed that the results indicate that in 6 experiments with 3 different invertase preparations the invertase is acting alike throughout

the course of the reaction. The results of the last 4 experiments, on the other hand, while agreeing among themselves, do not agree well with the other results beyond about the first 20% of the inversion. This indicates that invertase preparation No. 3 is in some way different from the other preparations, since the latter part of the reaction is noticeably slower. These results therefore show that not all preparations of invertase have, under a given set of conditions, the same degree of activity. It was thought at first that this retardation might be due to spontaneous destruction of the enzyme. That this was not the case is shown by the results of experiment B15, for in this case the invertase was kept in the thermostat for 5 hours before the start of the reaction. It has been shown by O'Sullivan and Tompson<sup>3</sup> that invertase suffers spontaneous destruction less rapidly in the presence of sucrose than in its absence. Since the results of Expt. B15 indicate no loss in activity of the invertase in 5 hours without the presence of sucrose, it is evident that the difference in the action of invertase preparation No. 3 cannot be due to spontaneous destruction of the enzyme. Table I proves, therefore, that while there seems to be a normal course for invertase action, there are also exceptions or abnormal invertase preparations.

### III. Discussion of Equations for Invertase Action.

If a general equation for normal invertase action were available, it would be comparatively easy to ascertain from experimental data whether any given preparation were normal or abnormal. Nelson and Vosburgh<sup>1</sup> and others have shown that the rate of hydrolysis of cane sugar by invertase is not proportional to the concentration of the substrate, or, in other words, the reaction does not obey the unimolecular law,

$$\frac{1}{t} \log \frac{a}{a-x} \quad (1)$$

where  $k$  is the velocity coefficient,  $t$  time in minutes,  $a$  the initial cane sugar concentration and  $x$  the amount hydrolyzed.

Henri<sup>4</sup> proposed an empirical equation containing only one constant.

$$k = \frac{1}{t} \log \frac{a+x}{a-x}. \quad (2)$$

When this equation was applied to the results with normal invertase given in Table IA, decreasing values for the constant were obtained.

Equations of the form

$$t = k_1 \log \frac{a}{a-x} + k_2 x. \quad (3)$$

<sup>3</sup> O'Sullivan and Tompson, *J. Chem. Soc.*, 57, 834 (1890).

<sup>4</sup> Henri, "Lois générales de l'action des diastases," Hermann, Paris, 1903, p. 59.

were deduced by Henri<sup>5</sup> and Bodenstein,<sup>6</sup> by Barendrecht,<sup>7</sup> Michaelis and Menten,<sup>8</sup> and Van Slyke and Cullen.<sup>9</sup> On applying the method of least squares to the present results (Table IA) to determine the constants for an equation of this type, it was found that such an equation would not hold satisfactorily for the whole course of the reaction. However, by using the values obtained for the first half of the hydrolysis only, the following equation, obtained by least squares, was found to hold for the first 50% of the hydrolysis.

$$t = 135.2 \log \frac{100}{100-p} + 0.9724 p. \quad (4)$$

Here  $t$  is the number of minutes required for  $p$  per cent. of the sucrose to be inverted. When  $p$  is expressed in the notation of Equation 1 it is equal to  $100 x/a$ . The accuracy with which the equation fits the results may be seen from the following figures.

$p$ .	$t$ (calc.).	$t$ (obs.).	$p$ .	$t$ (calc.).	$t$ (obs.).
3.15	4.94	5	18.52	30.0	30
6.35	10.0	10	35.43	60.1	60
9.37	14.9	15	50.27	89.9	90
13.77	22.1	22			

By considering the hydrolysis of sucrose as a reversible reaction, uni-molecular in one direction and bimolecular in the other, Visser<sup>10</sup> deduced an equation which, in the symbols previously used, takes the form

$$\frac{dx}{dt} = k_1(a-x) - k_2x^2. \quad (5)$$

On applying this to his experiments he obtained increasing values for a quantity which should theoretically have been constant. In order to correct for this increase he introduced a factor  $I$  to which for some reason he attributed a chemical significance, and called it "the intensity of the enzyme," giving the equation:

$$\frac{dx}{dt} = [k_1(a-x) - k_2x^2]I. \quad (6)$$

The values of  $I$  he obtained from the increasing values of the constant obtained from Equation 5, and he found they could be expressed by the empirical formula

$$I = \frac{k_3}{7a^2 - 4ax + x^2}. \quad (7)$$

By substituting this expression in Equation 6 and integrating he obtained

<sup>5</sup> *Op. cit.*, p. 79.

<sup>6</sup> Bodenstein, *ibid.*, p. 92.

<sup>7</sup> Barendrecht, *Z. physik. Chem.*, 49, 456 (1904).

<sup>8</sup> Michaelis and Menten, *Biochem. Z.*, 49, 333 (1913).

<sup>9</sup> Van Slyke and Cullen, *J. Biol. Chem.*, 19, 141 (1914).

<sup>10</sup> Visser, *Z. physik. Chem.*, 52, 257 (1905).

a complicated equation which gave constants satisfactory to about  $\pm 10\%$ . Since Hudson<sup>11</sup> has shown Visser's theory of reversibility to be unsound, no attempt was made to apply this equation to the present results.

Visser also proposed a simpler equation for invertase action, obtained by neglecting the reverse reaction, but putting the same factor  $I$  into the unimolecular equation.

$$\frac{dx}{dt} = k(a-x)I = k(a-x) \frac{d_2}{7a^2 - 4ax + x^2} \quad (8)$$

This on integration becomes

$$2k_1 k_2 t = 8a^2 \ln \frac{a}{a-x} + x(6a-x) \quad (9)$$

Visser's application of this equation to his own experiments gave "constants" which showed an extreme variation of 30% (0.00108 to 0.00139) and an application of the same equation to the experiments of Table IA likewise gave increasing values for the constant.

An equation of similar form,

$$t = k_1 \log \frac{a}{a-x} + k_2 x + k_3 x^2, \quad (10)$$

was obtained from the data of Table IA by the method of least squares, but did not fit the experimental data well enough to be of any use in the present work.

In order to get satisfactory agreement with the experimental data, it was found necessary to use an equation containing four constants. The following equation was obtained by applying the method of least squares to the mean results of the 6 experiments in Table IA.

$$t = 222.9 \log \frac{100}{100-p} + 0.5890p - 0.001975p^2 - 0.00002034p^3. \quad (11)$$

The applicability of this equation may be seen from the following figures.

#### IV. An Equation for Experiments with Different Amounts of Invertase.

Nelson and Vosburgh<sup>1</sup> showed that, in their experiments in which the initial sucrose concentration was constant, the time required for a given percentage of sucrose to be inverted was inversely proportional to the amount of invertase used. In other words, letting  $t$  represent the time for 80% inversion, and  $y$  the invertase concentration, in experiments in which only the invertase concentration was varied they found the product  $ty$  to be constant. In another series of experiments with a different invertase preparation they called  $t$  the time for 40% inversion, and here again  $ty$  was constant. They did not, however, compare the times for different degrees of inversion in any one experiment, say  $t$  for 40% and  $t$  for 80% inversion, because they did not know the law governing the relationship between the time and the percentage of inversion, or, mathematically, the form of the function,  $t=f(p)$ .

It is obvious that one may plot the values for the amounts hydrolyzed in various times against the times, obtaining curves for the hydrolyses which are graphical representations of the function,  $t=f(p)$ . This was done by Michaelis and Davidsohn<sup>12</sup> in such a way as to compare the form of the function in three experiments with invertase concentrations in the ratio 2:1:0.4. They plotted the product of the enzyme concentration and the time,  $ty$ , against the change in rotation, which is proportional to the percentage inverted,  $p$ . They claimed that the points all fell on a smooth curve, and that therefore the form of the hydrolysis curve was independent of the amount of enzyme. However, only 3 experiments were given of which one was represented by only 2 points. Moreover, their whole curve did not appear to extend much beyond the first half of the inversion, and in addition several of their points did not fall on the curve, even on the small scale used in their printed article. Because of these deficiencies, and because the shape of the curve is a fundamental point in the present investigation, it seemed best to amplify their data by the use of the more extensive experiments of Nelson and Vosburgh.

Accordingly the results of the latter were plotted in a similar way on a large scale. The curves were brought together at one point by using a different time scale for each experiment. When the remainder of each curve was plotted on this new scale, it was found that the curves for experiments with the same initial sucrose concentration did superimpose, falling on a single smooth curve. Thus the conclusion drawn by Michaelis and Davidsohn was more firmly established by the results of Expts. 6, 7, 8, 9, 10, 22 and 23 of Nelson and Vosburgh, each experiment including at least 6 samples and extending over 95% or more of the inversion. This means that the function,  $t=f(p)$ , representing a single experiment, can be generalized as  $nt=F(p)$  for experiments with varying amounts of invertase.

<sup>12</sup> Michaelis and Davidsohn, *Biochem. Z.*, 35, 386 (1911).

Here  $n$  is a constant in any one experiment, but varies in different experiments, being proportional to the amount of effective invertase. Moreover the form of the function  $nt = F(p)$  is, within the limits of these experiments, independent of the amount of invertase or of the rate of the hydrolysis.

A more exact verification of this relationship was obtained by the use of Equation 11, which gives a definite form to the function,  $t = f(p)$ , for one particular invertase concentration. In order to make this equation generally applicable to experiments with other invertase concentrations, the coefficient of the logarithmic term was placed equal to  $1/n$  and factored out, giving

$$t = \frac{1}{n} \left[ \log \frac{100}{100-p} + 0.002642p - 0.000008860p^2 - 0.0000001034p^3 \right]. \quad (12)$$

If it is generally true that the times for any given percentage of inversion are inversely proportional to the amounts of invertase used, then Equation 12 gives a definite form to the function,  $t = f(p)$ , for any invertase concentration. Whether or not this is the case can be tested by substituting in Equation 12 the experimental values for  $p$  and  $t$ , and calculating the values of  $n$ . If the latter are constant, the equation applies and the general law holds, and the values of  $n$  should be directly proportional to the amounts of active invertase present.

To recapitulate, we have, if this is true, first an empirical relation between time and percentage inverted which holds for experiments in which different amounts of invertase are used; and, second, we have in the value of  $n$  a relative measure of the amount of the effective invertase.

In order to decide whether or not Equation 12 applies to a given experiment, it is necessary to decide whether or not the values of  $n$  are constant. The values of  $n$  for the experiments of Table IA, from which the equation was derived, are given in the last column of Table II. The average deviation from the mean, 0.36%, is an indication of the extent to which the equation fits these original experiments. To determine about what magnitude of deviation from the mean might be due to experimental error in applying the equation to other experiments, the following calculations were made.

From the agreement of duplicate experiments in Table I and subsequent experiments, the average error in determining any change in rotation was estimated as  $0.02^\circ$ . To determine what error in  $n$  could be caused by such an error, the value  $0.02^\circ$  was added to all the changes in rotation of Table IA, and the values of  $n$  recalculated, with the results shown in Table III.

Evidently the form of the relationship is such that errors are magnified in the values of  $n$  calculated from the data on the early part of the hydrolysis. Since in all the experiments of the present work except those of Table I the first sample was taken at about 10% inversion, while the

other 7 samples were distributed about as before, it was decided that a fairer measure of the average error in  $n$  would be given by the mean of the last 8 of the above values. This gives an average deviation of 0.59% from the individual values of  $n$ , or of 0.70% from the mean value of  $n$  as the deviation caused by an error of  $0.02^\circ$  in the value of each change in rotation. Hence it may fairly be decided that any experiment giving an average deviation from the mean of 0.7% or less is fitted by the equation, and its curve has the same shape or the function,  $nt = F(p)$ , has the same form as in the case of the original experiments of Table IA.

Since the results of Nelson and Vosburgh were available, including experiments in which the concentration of invertase was varied, it was thought that these results might well be used as a test of the general applicability of Equation 12. Accordingly Table IV was prepared by using those of their experiments in which the initial sucrose concentration was 10 g. per 100 cc.

In the last three of these experiments the average deviation from the mean of the values of  $n$  is below the value 0.7%. As has been already pointed out, this deviation might be caused by experimental error, and accordingly the equation fits these three experiments satisfactorily. In Expts. 6, 8, and 9 the first sample was taken before the inversion was 10% complete. Now it has been already pointed out that in this part of the inversion a small experimental error may cause a large error in the value of  $n$ . Accordingly for these experiments the mean of the remaining values of  $n$  was calculated, omitting the first, and the average deviations were found to be 0.64%, 0.40%, and 0.10% for Expts. 6, 8 and 9, respectively. Therefore the equation really does fit 6 of the 7 experiments in Table IV, and it may be concluded with more certainty than before that the shape of the hydrolysis curve or the form of the function,  $nt = F(p)$ , is independ-

ent of the invertase concentration, and that Equation 12 gives a definite form to this function,  $F(p)$ .

In view of the fact that the extreme variation in the invertase concentration in these experiments was from 6 cc. to 2 cc. or in the ratio 3:1, while the range covered by the rather unsatisfactory experiments of Michaelis and Davidsohn was 5:1, it seemed best to try the effect of a wider variation

in invertase concentration on the shape of the curve. The highest concentration used was selected so as to make the hydrolysis as rapid as possible without causing error in the timing of samples, and the lowest concentration was such that the first and last samples could just conveniently be taken on the same day. In view of the difficulty encountered in a previous investigation<sup>13</sup> in obtaining reproducible results with very dilute invertase solutions, it seemed unwise to attempt to study slower reactions than this. The results of the experiments with the extreme invertase concentrations used, in the ratio 12:1, are given in Table V.

The values of  $n$  are sufficiently constant so that the equation may be said to hold for these concentrations.

If the time for any given percentage of inversion is inversely proportional to the concentration of invertase, the value of  $n$  divided by the number of cubic centimeters of invertase used per 100 cc. of solution should be a constant for any given invertase preparation. For Expts. B1 and B2 (Table IA) this value is 0.00292; for Vosburgh and Nelson's Expt. 1B (Table VI), it is 0.00290; for B60 and B61, 0.00278; and for B62, 0.00270. These experiments were all made with Invertase 8. The difference between the former two and the latter two values is due to slow deterioration of the invertase, even when kept in the ice-box, for a period of 8 months had elapsed between the two sets of experiments. The smaller difference between the latter two values can hardly be so explained, as the experiments were run on successive days, but must be taken to mean that for this range of concentrations the effective activity of the invertase is not strictly proportional to the actual concentration used. However, since the equation applies equally well in both cases, it may be stated as a fact

<sup>13</sup> Nelson and Hitchcock, "The Activity of Adsorbed Invertase," *THIS JOURNAL*, 43, 1956 (1921).

that over this range of invertase concentrations (12:1) the form of the function,  $nt = F(p)$ , is the same and is expressed by Equation 12, while the value of  $n$  represents accurately the true activity of the invertase even better than its relative concentration.

### V. Effect of Temperature.

Since the experiments of Nelson and Vosburgh were carried out at 37° while the present experiments were run at 25°, it seemed that the effect of temperature differences in any two experiments might be constant for all stages of the reaction. Inasmuch as some experiments on the course of the hydrolysis at various temperatures had recently been made in this

laboratory by Vosburgh and Nelson,<sup>14</sup> it seemed inadvisable to repeat this work. Accordingly the effect of temperature on the shape of the hydrolysis curve was tested by applying Equation 12 to these experiments, with the results shown in Table VI.

In all of these experiments the first sample was taken at a point considerably below 10% inversion. Therefore, in order to compare the average deviation with that which might be due to experimental error, the values obtained from the first sample should be omitted in taking the mean. If this is done the values for the average deviation are as follows: Expt. 11B, 0.68%; 15B, 0.91%; 1B, 0.34%; 5B, 0.43%; and 7B, 0.56%. All of these except that for Expt. 15B are less than 0.7%, and accordingly Equation 12 fits these experiments fairly well. This establishes for the first time the fact that temperature differences, at least between 15° and 35°, have no effect on the shape of the hydrolysis curve or the form of the function,  $nt = F(p)$ . In other words, an increase in the temperature has the same quantitative effect as an increase in the amount of the invertase used.

#### VI. Effect of Hydrogen-ion Concentration.

In his classical study of the effect of hydrogen-ion concentration on invertase action, Sørensen<sup>15</sup> found that the velocity coefficient  $k$  calculated according to the unimolecular law in the form

$$k = \frac{1}{t_2 - t_1} \ln \frac{a - x_1}{a - x_2}$$

increased considerably as the reaction progressed in nearly neutral solutions ( $C_{H^+} = 10^{-6}$  to  $10^{-7}$ ), increased less around the optimum ( $C_{H^+} = 10^{-4}$  to  $10^{-5}$ ), remained constant in slightly more acid solutions ( $C_{H^+} = 1.2 \times 10^{-4}$ ), and decreased in still more acid solutions ( $C_{H^+} = 2.1 \times 10^{-4}$ ). This means that the shape of the hydrolysis curve or the form of the function  $nt = F(p)$  was not the same, in his experiments, for different hydrogen-ion concentrations. Michaelis and Davidsohn<sup>12</sup> have pointed out that this variation may be explained in part by destruction of the invertase in the more acid solutions at the rather high temperature, 52°, at which Sørensen carried on his experiments. By using a lower temperature, 22.3°, they obtained values of  $k$  calculated from the equation

$$k = \frac{1}{t} \log \frac{a}{a - x}$$

which increased in experiments at hydrogen-ion concentrations less than  $3.0 \times 10^{-3}$ , where they remained constant. Nelson and Vosburgh,<sup>1</sup> on the other hand, found that at 37° the values of  $k$  increased in experiments

<sup>14</sup> Vosburgh and Nelson, "The Temperature Coefficient of Invertase Action," (to be published later).

<sup>15</sup> Sørensen, *Biochem. Z.*, 21, 131-304 (1909); also *Compt. rend. Lab. Carlsberg*, 8, 1 (1909).

at the optimum hydrogen-ion concentration,  $3.2 \times 10^{-5}$ , but increased more slowly or remained constant at  $3.2 \times 10^{-6}$ . They noticed, however, that there were some changes in the hydrogen-ion concentration during the latter half of the inversion at about  $3.2 \times 10^{-6}$ .

The equation of the present work will not fit experiments in which the values of the unimolecular " $k$ " are constant or decrease, because it was derived for experiments for which the unimolecular " $k$ " increased. In order to test the effect of hydrogen-ion concentration on the shape of the curve the equation was applied to some recent experiments of Vosburgh and Nelson (to be published later) in which the hydrogen-ion concentration was held constant at  $10^{-6}$  moles per liter by means of citrate buffers and the improved procedure recommended by Vosburgh<sup>18</sup> was used. These results are given in Table VII.

Except for the first value in Expt. 13B, the deviation of which may be due to a slight experimental error, as has been already pointed out, the constancy of  $n$  is very satisfactory. This means that at a hydrogen-ion concentration of  $10^{-6}$  moles per liter the curve has the same shape or the

<sup>18</sup> Vosburgh, "Some Errors in the Study of Invertase Action," THIS JOURNAL, 43, 1693 (1921).

function  $nt=F(p)$  has the same form as at the optimum hydrogen-ion concentration. The differences found by Nelson and Vosburgh<sup>1</sup> at  $C_{H^+} + 3.2 \times 10^{-6}$  must be ascribed to changes in the hydrogen-ion concentration or in the amount of active invertase due to the use of hydrochloric acid without buffer. The nature of the buffer, however, does not seem to affect the shape of the curve, for the experiments of this present work were made with a 0.01 *M* buffer mixture of acetic acid and sodium acetate, while the experiments of Vosburgh and Nelson (Tables VI and VII) were made with a similar concentration of sodium citrate. Very recently the range for which the equation has been extended to  $C_{H^+} + 3.2 \times 10^{-7}$  by some experiments of Bloomfield (not yet published). These results mean that within the limits given changes in hydrogen-ion concentration affect the activity of the invertase in just the same way as changes in temperature or in the amount of invertase used; either there is actually a change in the amount of the active substance present throughout the experiment or else the activity of the amount present is uniformly reduced or increased by the change and remains constant throughout the experiment.

### VII. A Criterion of Normal Invertase Action.

Above, in Part II of this paper, experiments were given which showed that not all invertase preparations impart the same shape to the hydrolysis curve. Equation 12 was made to fit the experiments in Table IA, made with invertase preparations which were classified as normal. Accordingly it seemed probable that it would not fit the experiments in Table IB, and hence might be used as a means of distinguishing between normal and

abnormal invertase preparations. Equation 12, therefore, was applied to the results of Table IB, and also to experiments with two other invertase preparations, Nos. 6 and 7, with the results shown in Table VIII.

				Av. dev., 0.56%.

It will be noticed in Expts. B12-15, Table VIII, that for those points where the data of Table IB coincided with those of Table IA, or up to 20% of the inversion, the values of  $n$  are fairly constant, even for abnormal invertase. The abnormality, however, shows up later in the decreasing values of  $n$ , and is indicated by the larger values of the average deviation of a single value of  $n$  from the mean, which is well above 0.7% for the experiments with Invertase 3. Expts. B17 and B18 indicate that Invertase 6 is also an abnormal invertase preparation, since the values of  $n$  decrease and the average deviation is well above 0.7%. Invertase 7, on the other hand, is a normal invertase preparation, as is shown by Expts. B20 and B21, since the values of  $n$  exhibit satisfactory constancy. These experiments indicate that Equation 12 may be used as a criterion of normal invertase action. In order to decide whether invertase preparations are normal or abnormal, then, it is no longer necessary to use them at initially equivalent effective concentrations, but the experiments may be made with any concentration, at least within the limits of the experiments in Table V. If the average deviation of the values of  $n$  is under 0.7%, the invertase preparation may be classified as normal; if the values of  $n$  decrease and the average deviation is much over 0.7%, then the invertase preparation is abnormal.

### VIII. Attempts to Make the Abnormal Invertase Act Normally.

There were no known differences in the method used in obtaining the normal and abnormal invertase preparations. However, it was deemed advisable to find out whether the abnormality could be due to some im-

purity which might be removed by further dialysis. Accordingly a sample of Invertase 6 was dialyzed for 3 days more in a collodion bag against running tap water. During the dialysis its volume was about doubled and its activity decreased by about  $\frac{1}{2}$  on that account; this was designated as Invertase 6B. To avoid this loss in activity, a sample of Invertase 3 was concentrated by evaporation in a collodion bag by fanning at room temperature<sup>17</sup> until it had lost about half its volume, and then dialyzed for 4 days, when it had regained about its original volume; this was designated as Invertase 3B. The results of experiments with these dialyzed preparations are given in Table IX.

		Mean,	466				
		Av. dev.,	1.76%.				

The decrease in the values of  $n$  and the large average deviations show that the invertase was still abnormal.

Since the abnormality could not be removed by purification by dialysis, it was thought that it might be due to the absence of some substance contained in the normal invertase. A sample of Invertase 8 was inactivated by boiling, and was proved to be totally inactive by the absence of any action on sugar solutions. Experiments were then conducted in which the solutions contained 10 cc. of this inactive invertase per 100 cc. in addition to the abnormal invertase under investigation. The results are given in Table X.

The figures in Table X indicate that the presence of boiled normal invertase caused preparation No. 3 to act normally, giving constant values of  $n$ , while it was practically without effect on preparation No. 6. This apparently means that there are different kinds of abnormality in different invertase preparations.

In order to show that preparation No. 3 had not become normal simply on standing, but that the normal course of the reaction was really produced by the presence of the boiled invertase, other experiments were run with Invertase 3 alone, and were found to give decreasing values of  $n$ , as before. These values, however, were somewhat smaller than those obtained in Expts. B12 to B15, indicating that this preparation had appreciably lost activity on being kept in the ice-box for less than 5 months.

Further experiments were made with the abnormal invertase preparations Nos. 3 and 6 in the presence of different concentrations of sodium chloride. The results are given in Table XI.

The figures in Table XI indicate that increasing concentrations of sodium chloride exert an increasing retarding effect on the action of the

invertase. This was not observed in the work of Fales and Nelson<sup>18</sup> at the optimum hydrogen-ion concentration, but this may be due to the fact that they worked with a very much smaller sugar concentration, 0.5 g. per 100 cc. This retardation, however, seems to have more effect at the beginning of the hydrolysis than at the end in the case of Invertase 3, for in Expt. B42, with 0.1 *M* sodium chloride, the values of  $n$  were constant and the action must be classed as that of normal invertase. Invertase 6, however, was not made normal by 0.1 *M* sodium chloride, for in Expt. B48 the values of  $n$  decreased as much as ever. An experiment with 0.5 *M* sodium chloride and Invertase 6 gave values which decreased somewhat less, but still were not constant enough for the action to be regarded

<sup>18</sup> Fales and Nelson, *THIS JOURNAL*, 37, 2769 (1915).

as normal. Unfortunately the supply of Invertase 6 became too low for further experiments to be carried out with it.

Further experiments were made with Invertase 3 to determine the effect of invertase concentration on the abnormal action. The results are given in Table XII.

These results show that in the case of Invertase 3 the abnormality decreases with increasing amount of invertase or increases with decreasing amount of invertase or increasing time of reaction.

It is not possible to explain these changes in the abnormality of Invertase 3 at the present time.

### IX. Attempts to Make Normal Invertase Become Abnormal.

Since the presence of sodium chloride had seemed to some extent to favor the normal course of invertase action, it seemed worth while to find out whether further dialysis, by removing any last traces of salt, could

make a specimen of normal invertase act abnormally. Accordingly a sample of Invertase 8 was dialyzed for a week in a collodion bag against 8 changes of distilled water. This was designated as Invertase 8A, and when tested was found to be still normal, as is shown by the results in Table XIII, Expt. B46.

Another sample of Invertase 8 was partially inactivated by heating for 1 hour on a water-bath at 50°, and then for 1/2 hour more at about 57°. This reduced its activity by about one-half. This invertase, No. 8E, was also found to be still normal, as is shown by Expts. B50 and B51, Table XII.

A further attempt to render Invertase 8 abnormal was made by exposing some of it for 2 hours, in a quartz flask, to the ultraviolet and other radiation given by a mercury arc lamp. The result, Invertase 8F, had about one-half the activity of Invertase 8, but was also found to be still normal, as is shown by Expts. B52 and B53, Table XIII.

				Av. dev., 0.38%.				

Since the values of  $n$  in Table XIII are constant in each experiment, having an average deviation from the mean in each case of less than 0.7%, the results show that the invertase was still acting normally. Hence it may be concluded that it is not possible by any of these three methods of treatment to render a normal invertase preparation abnormal.

### X. Experimental Details.

**Preparation of materials.**—The invertase used was all obtained from yeast by the method of Nelson and Born,<sup>19</sup> with slight modifications as described below. Preparations 6 and 7 had been made by previous workers in this laboratory and had been kept for several years in solution, saturated with toluene, in an ice-box. Preparations 1, 2 and 3 were made from yeast which had been permitted to autolyze for about a month and then filtered, and the filtrate had been treated with toluene and kept in stoppered bottles at room temperature for three years or more. During this time more solid matter had separated, and this was filtered off and the filtrate treated according to the method described by Nelson and Born<sup>14</sup> with the following modifications. Only one precipitation with alcohol was used and the kaolin treatment was omitted. After treatment with lead acetate and potassium oxalate, the filtrate was dialyzed for from 4 to 6 days in collodion bags against running tap water. The solutions become colorless and nearly clear during the dialysis. The dialyzed solutions were not precipitated again, but were preserved with toluene and kept in the ice-box until needed for the experiments. Preparation No. 8 was prepared by the same method from a new lot of 100 pounds of pressed yeast.<sup>20</sup> The preparation of Invertase No. 2 was carried out by Nelson and Simons,<sup>21</sup> who modified the treatment further by nearly neutralizing the solution with ammonia before the alcohol precipitation. No differences in the method of preparation are known which might account for the abnormality of invertase preparations Nos. 3 and 6.

Two lots of sucrose were used. In each case the starting point was the best commercial sugar, which was dissolved in distilled water and clarified with charcoal. The first lot was precipitated by alcohol by the method of Cohen and Commelin.<sup>22</sup> Its rotation was found to agree within 0.1% with that calculated from the formulas of Landolt and Schönrock.<sup>23</sup> The second lot was recrystallized from water by a procedure similar to that of Bates and Jackson.<sup>24</sup> Its rotation agreed with the calculated value within 0.04%.

Other chemicals were c. P. grades used without further purification.

<sup>23</sup> Browne, "A Handbook of Sugar Analysis," John Wiley and Sons, New York, 1912, pp. 177-8.

<sup>24</sup> Bates and Jackson, *Bur. of Standards Sci. Papers*, No. 268, 75 (1916).

**Apparatus.**—Constant temperature was obtained by the use of an electrically controlled water-bath which remained at  $25^{\circ} \pm 0.01^{\circ}$ .

The progress of the inversion was followed by means of a Schmidt and Haensch polarimeter reading to  $0.01^{\circ}$ . The tubes used were 200 mm. long, and were proved to be of the same length by observing the rotation of the same 10% sugar solution in each tube. The temperature of the tubes was kept constant by the thermostat described by Nelson and Beegle,<sup>25</sup> which maintained a temperature of  $25^{\circ} \pm 0.05^{\circ}$ .

Monochromatic light of wave length  $546.1 \mu\mu$  was obtained from a mercury vapor arc by purification through two Wratten filters, one a No. 77, and the other a No. 77 which had been re-cemented with a green film in place of the yellow one. Thanks are due to Dr. C. E. K. Mees of the Eastman Kodak Company for preparing these filters. This light made it possible to use the polariscope with a half-shadow angle of  $0.5^{\circ}$ .

Nonsol bottles were used to contain the solutions undergoing hydrolysis. All volumetric apparatus used in making up solutions was calibrated.

**Control of the Hydrogen-ion Concentration.**—The desired hydrogen-ion concentration was obtained by the use of a buffer mixture of 0.1 *M* acetic acid and 0.1 *M* sodium acetate in the proportions given by Michaelis.<sup>26</sup> One hundred cc. of the final solution always contained 10 cc. of this buffer, making the total concentration 0.01 *M*. This concentration was low enough so that any salt effect on the invertase action was negligible, especially at the optimum hydrogen-ion concentration.<sup>18</sup> In the experiments of Nelson and Vosburgh<sup>1</sup> the desired hydrogen-ion concentration was obtained by the use of diluted hydrochloric acid. In the experiments of Vosburgh and Nelson<sup>14</sup> a buffer of citric acid and secondary sodium citrate was used at a total citrate concentration of 0.01 *M*.

The hydrogen-ion concentration was measured during or after each inversion by the colorimetric method of Sørensen,<sup>15</sup> using  $\alpha$ -naphthyl-amino-azo-*p*-benzene sulfonic acid as indicator with citrate standards. The latter were standardized electrometrically with the hydrogen electrode and the saturated potassium chloride calomel cell<sup>27</sup> using a salt bridge of saturated potassium chloride solution. The hydrogen-ion concentrations were based on 0.1000 *M* hydrochloric acid as a standard, its ionization<sup>28</sup> being taken as 92.04% at  $25^{\circ}$ , the temperature at which the present determinations were made.

**Procedure.**—In general the procedure followed was that recommended by Vosburgh.<sup>16</sup> Duplicate experiments were run on different days with freshly prepared sugar solutions. A solution was made up containing

<sup>25</sup> Nelson and Beegle, *THIS JOURNAL*, **41**, 559 (1919).

sucrose and buffer in such concentrations that when a certain volume of this had been measured out it would be possible to add from a pipet a round number of cubic centimeters of invertase to start the reaction. For example, in Expt. B1 32.680 g. of sucrose and 32.68 cc. of buffer were diluted to 500 cc. at 25°. Of this solution 321.80 cc. was pipetted into a Nonsol bottle, and 5 cc. of invertase was added to start the reaction. This produced the initial concentrations given in Table I A. The solutions were stirred by a current of filtered air while being mixed, and samples were taken by pipets delivering in 10 seconds or less.<sup>21</sup> The time of mixing or of sampling was taken as the mean time of delivery of the pipet used. The reaction was stopped and mutarotation hastened by the use of sodium carbonate as recommended by Hudson,<sup>29</sup> a 25cc. sample being added to 5 cc. of 0.1 *M* sodium carbonate solution. The initial rotation of each solution was determined by preparing samples of identical composition in which the sodium carbonate was added to the sugar before the addition of the invertase, thus rendering the invertase entirely inactive. The rotation of each solution was determined by taking the mean of at least four concordant readings, the tube being rotated slightly after each reading to ensure the detection of any strain in the cover glasses.<sup>30</sup> The zero point of the polariscope was similarly determined by the use of a tube filled with distilled water. The final rotations were obtained by taking samples 2 days or more after the start of the reaction. Samples taken on the second and third days usually had the same rotation. In calculating the percentage inverted, the total change in rotation was always taken as 16.85°, since this value was obtained in all the experiments of Vosburgh and Nelson<sup>14</sup> as well as in the majority of the present experiments.

Since in several experiments the total change in rotation appeared to be a few hundredths of a degree more than 16.85°, it was thought advisable to test the effect of such differences on the values of  $n$  as obtained by the use of Equation 12. A sample calculation was made for Expt. B46, Table XIII, with the following results.

Using 16.85°, $n \times 10^4$ .		Using 16.89°, $n \times 10^4$ .	
505	501	504	498
504	502	503	497
501	499	500	492
499	Mean, 501	497	Mean, 498
497	Av. dev., 0.40%	495	Av. dev., 0.60%.

These results show that an error of 0.04° in determining the total change in rotation could not have caused sufficient error in the values of  $n$  to make a normal invertase preparation appear abnormal. Since this was the

<sup>29</sup> Hudson, *THIS JOURNAL*, 30, 1564 (1908).

<sup>30</sup> Browne, *Ref. 23*, p. 156.

extreme deviation noticed from the value  $16.85^\circ$ , the procedure adopted of taking the total change as  $16.85^\circ$  in all calculations is quite justified.

A calculation of the possible error in determining the rotation of any sample which might be due to errors in the various measurements of weight and volume involved in this procedure has been made by Messrs. G. Bloomfield and F. Hollander of this laboratory. Using estimates of these errors based on the present authors' calibrations, this calculation gave a maximum error of about  $0.01^\circ$  in the determination of the rotation of a sample. Since the duplicate experiments did not always agree so well as this, a fairer estimate of the precision of the measurements may be obtained from the agreement of the duplicates themselves. This would put the average difference between duplicate measurements of a change in rotation at about  $0.02^\circ$ . The effect of such an error on the values of  $n$  obtained by the use of Equation 12 has already been considered.

### Summary.

1. It has been shown that not all preparations of yeast invertase are alike in their action, but that some are abnormal in allowing the hydrolysis of cane sugar to slow up more than others after the first 20% of the inversion.
2. An empirical equation is given which fits the hydrolysis of cane sugar by normal invertase over an extreme range of invertase concentration of 12:1. By this means it has been shown that the hydrolysis-time curves for normal invertase are of the same shape for these different invertase concentrations and can be made to superimpose if the time scale be multiplied by the proper constant.
3. By the same method it has been shown that the hydrolysis curve with normal invertase has the same shape at temperatures varying from  $15^\circ$  to  $35^\circ$ , and at hydrogen-ion concentrations from  $4.0 \times 10^{-6}$  to  $3.2 \times 10^{-7}$ .
4. It was found that one abnormal invertase preparation could be rendered normal by the presence of boiled normal invertase or 0.1 *M* sodium chloride, while another was not affected by either. The former preparation also worked normally at a very high concentration.
5. It was found impossible to render a normal invertase preparation abnormal by further dialysis or partial inactivation by heating or ultra-violet light.

The authors are glad to acknowledge their indebtedness to the Harriman Research Laboratory, New York City, for financial assistance in this investigation.

## NITROGEN COMPOUNDS IN ALFALFA HAY.

BY HARRY G. MILLER.

Received August 22, 1921.

In an earlier paper results were reported on the distribution of nitrogen in the alfalfa seed. A similar study has now been made on a sample of alfalfa hay, although this phase of the investigation was begun before the work on nitrogen distribution in the seed was undertaken. The difficulty of separating the nitrogen compounds in the alfalfa hay prompted the writer to apply certain analytical methods to the seed to obtain information as to what nitrogen compounds might be present in the leaves and stems of the alfalfa plant. Results of the study to ascertain the nitrogen groups in alfalfa hay, while not complete, are reported in this paper, due to a discontinuance of this work for a year.

The sample of hay was grown in eastern Oregon and was cut at a time when the hay, according to agricultural practice, is best suited for feeding purposes. It contained 1.98% of nitrogen. Extracting 25 g. of finely ground alfalfa with ether followed by alcohol and then water in a Soxhlet extractor removed the following amounts of nitrogen given as percentages of the total nitrogen; ether, 0.85%; alcohol (95%), 5.32%; and water, 34.5%. In all 40.7% of the total nitrogen was removed. The residue from extraction weighed 15.71 g. and contained 1.86% of nitrogen. By difference, the solids dissolved would weigh 9.29 g. and contain 2.18% of nitrogen. In cold water 39.0% of the total nitrogen was soluble, 10% sodium chloride solution extracted an additional 9.8% and this followed by 0.2% potassium hydroxide solution brought the total up to 58.1%. Extracting directly with 0.2% potassium hydroxide solution removed 58% of the nitrogen of which 53% was precipitated with acetic acid leaving 27.3% of the total nitrogen in solution. Hot water extraction removed 28.7%; however, when this residue was further extracted with the potassium hydroxide solution only 4.5% of the total nitrogen was brought into solution compared to about 31% before. Heating the residue to the boiling point of water apparently changed the nature of the alkali-soluble nitrogen compounds. A 0.5% potassium hydroxide solution extracted more nitrogen from alfalfa which had been ground fine enough to pass through a 40-mesh sieve than from ordinary chopped alfalfa for feeding purposes. After the proteins were removed from these extracts the nitrogen content of the filtrates was the same, representing 27.7% of the total nitrogen. As an example 4 g. each of coarse and fine alfalfa were extracted with 0.5% potassium hydroxide solution; the total amounts of nitrogen extracted were 0.0325 g. and 0.0465 g. respectively. The weights of nitrogen precipitated as protein were 0.0111 g. from the coarse material and

0.0246 g. from the finely ground sample, leaving as non-protein 0.0214 g. and 0.0219 g., respectively. A cold-water extract of the fine material after removing the protein with acetic acid contained 28% of the total nitrogen, while a hot-water extract of the coarse alfalfa contained 27.8% of the nitrogen. Apparently there are certain nitrogen compounds which are very easily extracted with hot water, cold water or alkali, and after removing the protein from the two latter solutions the percentages of non-protein nitrogen extracted are the same regardless of the degree of fineness of the alfalfa. Alkali extracted about 100% more protein from the finer particles than from the chopped alfalfa.

Mixing the alfalfa flour with water and 0.5% potassium hydroxide solution and placing the sealed containers in a freezing mixture of ice and salt ( $-20^{\circ}$ ) did not cause more nitrogen to be extracted, but rather less; the water solution contained 29.2% of the total nitrogen and the alkali extract 40.8%. Subjecting a 3g. sample of alfalfa to the crude fiber determination did not extract all of the nitrogen, as 7.3% still remained. The dilute sulfuric acid (1.25%) removed only 8.5%, while the following sodium hydroxide solution (1.25%) extracted 49.1%. The preceding extraction with ether and water removed 0.9% and 30% nitrogen, respectively. The 4.2% not accounted for was most probably removed as ammonia in the sodium hydroxide digestion.

### Protein Nitrogen.

A preparation of protein for applying the Van Slyke method to determine certain nitrogen groups was obtained by extracting the alfalfa with 0.5% potassium hydroxide solution. Nearly all the extract was obtained by using a press. The solution after filtering was acidified with either acetic or hydrochloric acid to precipitate the protein. The protein was then extracted with absolute alcohol in a Soxhlet extractor until the extract was practically colorless, the alcohol was washed out with ether and the protein dried in a vacuum desiccator over sulfuric acid. Analysis showed for nitrogen, 12.9%; for sulfur, 0.85%; and for ash, 1.27%. No preparation of protein contained over 13% of nitrogen in spite of repeated precipitation and thorough alcohol extraction. After the protein was dried it would not dissolve in alkali in the cold and only with difficulty in an alcoholic-alkali solution (50.0 cc. of alcohol+50 cc. of 1% potassium hydroxide solution). Decomposition of the protein took place in the latter process.

After this work had been completed, Dowell and Menaul<sup>1</sup> reported results on nitrogen distribution of some proteins obtained by dilute alkali extraction. The protein they obtained from alfalfa contained 13.6% nitrogen ( $0.85 \times 0.16$ ). Chibnall and Schryver<sup>2</sup> obtained proteins from the green leaves of cabbage, spinach, bean, grass, etc., by extracting with water, using ether as a cytolytic agent. Their products sepa-

<sup>2</sup> Chibnall and Schryver, *Biochem. J.*, **15**, 60 (1921).

rated on warming this solution to 40°. When freshly prepared they were soluble in weak alkaline solutions from which they could be precipitated by acids. They contained about 13% of nitrogen. A protein preparation obtained by Osborne and Wakeman<sup>3</sup> from green spinach leaves contained 15.3% of nitrogen. They ground the fresh leaves with water, centrifuged out the cellular matter, after which they precipitated a substance containing 14% nitrogen. This was brought into solution with alkali and another precipitate obtained by adding acid which contained 15.3% nitrogen. This corresponds more nearly to nitrogen content of protein from seeds while in the results reported from the other workers the nitrogen content of the proteins in the leaves averages about 13.0%.

Results of analysis of the protein by the Van Slyke method are given in the following table. Two portions of Sample I weighing 3.2856 g. and 3.6353 g., equivalent to 0.4230 and 0.4681 g. of nitrogen, were hydrolyzed for 20 hours with 20% hydrochloric acid; 3.31 g. of Sample II, containing 0.4145 g. of nitrogen, was hydrolyzed for 30 hours. The percentage nitrogen distribution of the protein of the seed reported in an earlier paper<sup>1</sup> is given in the last column for comparison. So far as the writer knows there are no other data showing a comparison of the nitrogen distribution between a seed protein and the protein existing in the stems and leaves of the same plant, both obtained by the same method.

<sup>b</sup> Total nitrogen corrected for solubility of bases.<sup>4</sup>

An explanation as to why the nitrogen content of the leaf protein (13.0%) was lower than that of seed protein (15.6%) may be found in these data. The protein from the seed yielded a larger quantity of the basic amino acids

<sup>3</sup> Osborne and Wakeman, *J. Biol. Chem.*, 42, 1 (1920).

<sup>4</sup> Plimmer, "The Chemical Constitution of the Proteins. I. Analysis," Longmans, Green and Company, 1917, p. 107.

than the leaf protein; especially is this significant in the arginine content of the two proteins. Calculating the weight of arginine present from the above nitrogen distribution, 1 g. of seed protein contains 0.1032 g. of arginine, while the same weight of leaf protein contains 0.0558 g. of arginine. As arginine contains more nitrogen than any other amino acid thus far isolated, its replacing other amino acid groups in the protein molecule or direct addition to the same would increase the nitrogen content of the protein. Of course low arginine content does not mean low nitrogen content of the protein or *vice versa*, which is shown in tables<sup>5</sup> giving the nitrogen distribution in proteins. However, as further evidence will be given, analytical results show that there is an increase in concentration of the arginine group to total nitrogen as the nitrogen compounds pass from the leaves into the seed and this may explain the higher nitrogen content of the seed protein over the leaf protein. Distribution of nitrogen in the hydrolytic products of the whole alfalfa seed reported in the earlier paper<sup>6</sup> shows that 14.98% of the total nitrogen reacted as arginine nitrogen, and that this could all be calculated as coming from the protein present in the seed. Grindley, Joseph and Slater<sup>7</sup> report 7.68% arginine in the hydrolytic products of alfalfa hay. This compared with the arginine content of the seed shows the large difference in arginine concentration. In the Van Slyke method of determining arginine in the hydrolytic products of alfalfa hay and the whole seeds there may be other nitrogen compounds present liberating ammonia when boiled with the alkali solution, thus giving a higher arginine content than the actual amount present. This does not appear to be the case with alfalfa seed for reasons already mentioned. With hay this undoubtedly takes place as will be shown later in the discussion of the water-soluble nitrogen compounds, which would make the difference between the actual ratio of arginine to total nitrogen greater than the above figures show. Roxas<sup>8</sup> found that arginine gave up 2.3% of its nitrogen for humin formation; this reaction would have a tendency to lower the actual arginine nitrogen in the solution, although it should not interfere seriously with the above results.

Chibnall and Schryver<sup>2</sup> state that the protein isolated from cabbage was acidic in properties and on hydrolysis yielded an amount of ammonia corresponding to 5% of the total nitrogen. They comment as follows: "These results indicate that acidic proteins exist in the leaves, which when they pass into the resting stage in the seed, undergo amidization. Such proteins should contain a relatively small amount of nitrogen." The higher percentage of amide nitrogen in the seed protein compared to the

<sup>5</sup> Ref. 4, p. 107.

<sup>6</sup> Miller, *THIS JOURNAL*, 43, 906 (1921).

<sup>7</sup> Grindley, Joseph and Slater, *ibid.*, 37, 1778 (1915).

<sup>8</sup> Roxas, *J. Biol. Chem.*, 27, 71 (1916).

leaf protein recorded in the above table gives support to this view. It appears logical to assume from the presence of these groups with a high nitrogen concentration in the seed protein and the appreciable quantities of ammonium salts and other soluble nitrogen compounds in the green plant that as the plant matures these simple nitrogen compounds are gradually incorporated into the protein molecule, thus increasing the nitrogen content of the latter. The spinach used by Osborne and Wakeman may have reached a more advanced stage of maturity than the sample used by Chibnall and Schryver and on the above assumption should contain more nitrogen. No study has yet been made pertaining to the equilibrium existing between ammonium salts, amino acids and proteins during different stages of growth. A study of this kind would help solve the problem. The possibility of the leaf protein being combined with a nitrogen-poor prosthetic group must not be overlooked and the larger yield of humin nitrogen from the leaf protein may be due to a group of this nature. The percentage distribution of the nitrogen groups in the protein from alfalfa obtained by Dowell and Menaul<sup>1</sup> varies somewhat from our results. This is probably due to a different compound, the difference being caused by the isolation of the protein at a different stage of growth.

#### The Water-Soluble Nitrogen Compounds.

As indicated before there was a certain class of nitrogen compounds, not protein, easily extracted with hot water, cold water or dil. alkali. Little is known of the nature of these non-protein nitrogen compounds. Hart and Bently,<sup>9</sup> in their work on the character of water soluble nitrogen compounds in feeding stuffs determined the ammonia nitrogen, amide nitrogen and amino nitrogen. Steenbock<sup>10</sup> isolated stachydrin from a hot-water extract of alfalfa hay. Following the same method the writer was unable to obtain any stachydrin hydrochloride from the sample of alfalfa hay used in this investigation. In removing the purines by precipitating with silver nitrate in dil. nitric acid solution a heavy flocculent precipitate formed. A similar precipitate formed with silver nitrate in an ammoniacal solution. A portion of the solution obtained from the phosphotungstic acid precipitate of the water extract of alfalfa, which reacted strongly alkaline, was slightly acidified with nitric acid and 5% silver nitrate added until a test portion gave a brown precipitate with barium hydroxide. The resulting precipitate was filtered off, washed and suspended in warm water. Hydrogen sulfide was passed in to remove the silver as silver sulfide, and the filtrate was boiled to remove excess of hydrogen sulfide. A portion of this filtrate did not give the color reaction for the murexide test. Adenine and hypoxanthine do not respond to this test.<sup>11</sup> A portion of the solid obtained by allowing

<sup>9</sup> Hart and Bentley, *J. Biol. Chem.*, 22, 477 (1915).

<sup>10</sup> Steenbock, *ibid.*, 35, 1 (1918).

<sup>11</sup> Walter Jones, "Nucleic Acids," Longmans, Green and Company, 1914, pp. 89, 95.

the above filtrate to evaporate gave the characteristic ruby-red coloration with hydrochloric acid, zinc and sodium hydroxide.<sup>12</sup> Hypoxanthine and adenine give this test. A purine precipitate was obtained again by precipitating with small quantities of solid silver sulfate in the solution slightly acidified with sulfuric acid. The sulfuric acid alone gave no precipitate, so that the alkalinity of the solution or the carbon dioxide evolved could not be attributed to the presence of barium hydroxide or carbonate not removed. The silver precipitate was suspended in water to which a few drops of hydrochloric acid were added. This solution was made ammoniacal, the precipitate filtered off and thoroughly washed. It was then suspended in nitric acid, 1.10 sp. gr., and boiled. Particles of silver chloride were filtered off and the filtrate was allowed to stand for 24 hours. Small orange colored crystals separated, weighing 0.0780 g. and containing 23.50% of nitrogen. Nitrogen calculated in the hypoxanthine salt of silver nitrate corresponding to the formula  $C_5H_4ON_4 \cdot AgNO_3$  is 22.88%.

Aeration of water extract of alfalfa removed ammonia equal to 2.0% of the total nitrogen. After hydrolyzing with 10% hydrochloric acid for 10 hours, the clear extract, after filtering off the humin nitrogen, yielded ammonia nitrogen by aeration equal to 3.75% of the total nitrogen, and amino nitrogen equivalent to 14.0% of the total nitrogen.

In preparing the phosphotungstic precipitates used in this work, the quantity of the acid required to precipitate the basic nitrogenous compounds was exceedingly great when compared to the amount required in the hydrolyzed solution of the protein. A quantity of extract containing 0.4287 g. of nitrogen was hydrolyzed with 10% hydrochloric acid for 10 hours. This was then treated in the same way as in the Van Slyke method of protein analysis. Fifteen g. of phosphotungstic acid which precipitates the basic amino acids from protein containing the same amount of nitrogen did not precipitate all the compounds that form precipitates with the acid from this hydrolyzed water extract. A further addition of 200 cc. (15 g. of phosphotungstic acid per 100 cc.) did not precipitate all the above compounds after 48 hours' standing. The precipitates formed by further separate additions of two 50cc. quantities were filtered off and the total nitrogen determined. The first contained 6.16 mg. of nitrogen, and the second 5.0 mg. These results show what small proportions of nitrogen, the nature of which permits its precipitation by phosphotungstic acid, are removed by a large quantity of the acid, especially when compared to a hydrolyzed protein solution.

The residues obtained from decomposing the phosphotungstate precipitates with barium hydroxide and removing the excess of barium, as

<sup>12</sup> Allen, "Commercial Organic Analysis," P. Blakiston's Son and Co., 1913, Vol. 7, p. 335.

the carbonate never contained over 3.5% nitrogen. Using a similar water extract made alkaline with sodium carbonate, and adding mercuric chloride solution, a precipitate was obtained, which, after removing the mercury with hydrogen sulfide and evaporating the solution to dryness, left a residue containing 13% nitrogen. The high concentration of nitrogen in the residue from the mercury precipitation was partly due to ammonium salts. The phosphotungstic precipitate was decomposed in an alkaline solution and later heated when the carbon dioxide was passed in. This process would free the ammonia while the mercury precipitate was decomposed in an acid solution.

In order to compare the mercuric chloride and phosphotungstic acid precipitations, 1000 cc. of water extract from 200 g. of alfalfa hay was treated with a 20% lead acetate solution until no further precipitate formed. Excess of lead in the filtrate was removed by adding sodium carbonate in excess. After filtering off the lead carbonate this alkaline solution was heated in a water-bath in an evaporating dish for 12 hours to drive off the ammonia, and made up to 1000 cc. To a 200cc. portion, 20 g. of mercuric chloride was added and the mixture warmed to dissolve all the chloride. Another 200cc. portion was acidified with sulfuric acid to 5% strength and 200 cc. of a 20% phosphotungstic acid solution in 5% sulfuric acid was added. After 24 hours the precipitates were decomposed in the usual way. The mercury precipitate dissolved in dil. hydrochloric acid with the formation of a white crystalline salt which contained no nitrogen and was filtered off before the hydrogen sulfide was passed in. The residue from the mercury precipitate weighed 0.79 g. and contained 8.83% of nitrogen; the phosphotungstic acid residue weighed 1.02 g. and contained 3.3% of nitrogen. Time did not permit a comparison of the total quantity of nitrogen removed when phosphotungstic acid was added until no further precipitate formed. Excess of mercury was present in the above precipitation.

The precipitate formed by the addition of lead acetate was decomposed with dil. sulfuric acid and the total nitrogen determined in the filtrate from lead sulfate; 2.75% of the total nitrogen in alfalfa or 9.82% of the non-protein nitrogen was precipitated by lead acetate. Twenty per cent. of the nitrogen from the lead precipitate was given off as ammonia when boiled with 25% potassium hydroxide, which, calculated as arginine nitrogen, would be 40% of the nitrogen in the lead precipitate. The mercury precipitate contained 8.88% of the total nitrogen. The residue from the mercury precipitate was dissolved in water and the total nitrogen determined on precipitates obtained by adding silver sulfate to the solution slightly acidified with sulfuric acid, and when it was rendered alkaline with barium hydroxide. The purine fraction contained 36% of the total nitrogen and the histidine-arginine fraction 35%; 3.2% of the total nitrogen

was in the purine fraction. Whether all of this fraction is composed of purines would have to be determined by analysis; this amount of nitrogen separated in the purine fraction by following the analytical procedure recommended.<sup>13</sup> The presence of these purines would increase the percentage of arginine as determined by the Van Slyke method on hydrolyzing the whole alfalfa hay. This was pointed out by Brewster and Alsberg<sup>14</sup> in their work with yeast nucleic acid.

### Summary.

1. Certain non-protein nitrogen compounds composing about 28% of the total nitrogen were easily extracted with water regardless of the degree of fineness of the alfalfa hay.

2. Alkali extracted more protein from the finely ground material than from the coarse.

3. The protein from alfalfa hay extracted by dilute alkali, had a nitrogen content of 13.0% and contained the basic amino acids arginine, histidine, lysine and cystine.

4. The protein from the seed yielded larger quantities of arginine and amide nitrogen than the leaf protein, which may account for the difference in the total nitrogen of the two proteins.

5. The purine fraction contained 3.2% of the total nitrogen. A crystalline salt corresponding to the nitrogen content of hypoxanthine silver nitrate was obtained.

6. Mercuric chloride precipitation of the water extract gave a residue high in nitrogen after removing the mercury, apparently suitable for further investigation pertaining to the nitrogen compounds in alfalfa hay.

## CASTOR BEAN LIPASE, ITS PREPARATION AND SOME OF ITS PROPERTIES.

BY D. E. HALEY AND J. F. LYMAN.

Received August 25, 1921.

In the extended studies on lipases by Falk<sup>1</sup> and his associates little attention has been given to the most favorable conditions for the preparation and activity of the enzyme material. Taylor,<sup>2</sup> von Hoyer,<sup>3</sup> Jalander,<sup>4</sup> Tanaka,<sup>5</sup> Barton<sup>6</sup> and others have proposed methods of preparing and using castor bean lipase. In an attempt to study the action of castor bean lipase on various esters we encountered difficulties, first, in obtaining an active, approximately fat-free preparation which would act as a good emulsifying agent for water and fats; and second, in adjusting the conditions so that rapid and nearly complete hydrolysis of the fat might occur.

We have found that it is comparatively easy to overcome both of these difficulties; but, as far as we have been able to find, no one has yet described methods that can be followed with entire satisfaction.

### Preparation of Lipase Material from the Castor Bean.

An attempt was made to modify the procedure of von Hoyer with the hope of obtaining a very active lipase, free from fat and cell residues. Lipase "cream" was prepared by the method described by von Hoyer.<sup>3</sup> This was dried at room temperature and extracted with ethyl ether. The small residue insoluble in ether is designated "cream residue." A sediment which settled from the castor bean "milk" was also separated, dried and extracted with ether. The main portion, representing the cell walls and other insoluble constituents of the beans, was likewise dried and extracted. There were thus three fractions: (1) fat-free residue from castor bean "cream," (2) fat-free sediment from castor bean "milk," and (3) fat-free residue of cellular materials not emulsified or dissolved by grinding and mixing the beans with water. A comparative test for lipolytic activity showed that Fraction 3 was high in lipase, while the small residue from the "cream" contained relatively little enzyme.

The materials were mixed in test-tubes in the amount and order named; 0.1 g. of lipase preparation, 1.0 g. of olive oil and 0.6 cc. of 0.1 *N* acetic acid. The tests were incubated at 38° for 12 hours and the free fatty acids then determined by titration against 0.1 *N* alcoholic sodium hydroxide using phenolphthalein as indicator. Before making the titrations the contents of the tubes were transferred to flasks by means

TABLE I.

RELATIVE LIPOLYTIC ACTIVITY OF FAT-FREE RESIDUE FROM VON HOYER'S CASTOR BEAN "CREAM," SEDIMENT FROM CASTOR BEAN "MILK" AND MAIN INSOLUBLE RESIDUE.

Fraction.	Extent of Hydrolysis.	
	0.1 N NaOH. Cc.	%.
"Cream" residue.....	18.0	53
"Milk" sediment.....	23.6	69
Main residue.....	22.8	67

of 50 cc. of neutral alcohol. Without the alcohol satisfactory results cannot be obtained on account of hydrolysis of sodium soaps formed in the titration and also because of the insolubility of the fatty acids in water. All tests reported in this paper were made in duplicate. Corrections were made for reagents and "blank" digestions.

Since the fat-free residue from the "cream" was small and its lipolytic action relatively low, this material does not seem promising. The main residue is easily obtained in quantity and has a good degree of activity. Its physical condition is likely to be unfavorable, however, because on drying there is a tendency for it to assume a tough horny consistency; and in this condition it does not mix readily with water, nor act as a good emulsifying agent. Alcohol and acetone were tried as dehydrating agents. While they gave a lipase material of good physical condition, the lipolytic action was entirely destroyed or lost in the process. It is probable that alcohol and acetone are destructive to castor bean lipase.<sup>4</sup>

The most satisfactory lipase material that we have prepared, judging by its physical condition and by its activity in hydrolyzing fats, was obtained by a slight modification of Taylor's<sup>2</sup> method. Castor beans<sup>7</sup> are shelled by cracking the hull with a small hammer and peeling off the outer covering of the seed by hand. The kernels are ground as finely as possible in a food chopper, and extracted in a Soxhlet extractor with petroleum ether. The extracted material is then passed through a 40-mesh sieve. We have found low-boiling petroleum ether more satisfactory as a solvent for this purpose than ethyl ether, although the latter can be used. We have not attempted to concentrate or isolate the lipase from the fat-free kernels.

#### The Solubility of Castor Bean Lipase in Ether and in Ether-Fat Mixtures.

Taylor<sup>2</sup> states that lipase of castor beans is insoluble in ethyl ether but that it dissolves in a mixture of ether and fat. The following experiment tends to verify this statement. Four portions of 3 g. each of extracted bean powder were treated as follows: (1) 25 cc. of olive oil was added; (2) 25 cc. of olive oil and 100 cc. of ethyl ether were added; (3) 100 cc. of ethyl ether was added; (4) nothing was added. All were allowed to stand at room temperature for 4 days. The solvents were then removed by decantation and filtration and all 4 residues extracted with petroleum

<sup>7</sup> The castor beans were donated by the Baker Castor Oil Co., N. Y.

<sup>8</sup> Kita, *J. Chem. Ind. Tokyo*, 21, 1-5 (1918).

# CASTOR BEAN LIPASE.

If the acid is added to the enzyme material before the oil a complete loss of lipase is likely to occur. Barton<sup>6</sup> notes the better emulsion obtained when the oil is added to the enzyme material before the acid is introduced. This is undoubtedly an important point, but the danger of destroying the active enzyme by acid in the absence of fat is a more serious consideration.

## The Concentration of Acid Most Favorable to the Hydrolysis of Fats by Castor Bean Lipase.

Although many experiments have been performed to determine the effect of acid on castor bean lipase we are not aware that the most favorable concentration, expressed in terms of actual acidity, has been determined. Barton's<sup>6</sup> conclusion that castor bean lipase has its optimum activity toward the three substances, lard, olive oil and ethyl butyrate at approximately 0.6% concentration of hydrochloric acid seems quite unjustified by his own data and in entire conflict with our results. We have repeated some of Barton's experiments and, under the conditions of his tests, find little if any activity. In view of the uncertainty of the accuracy of corrections made for "blank" experiments, small digestion values appear to us to have little significance. This is borne out by the fact that negative values were obtained in many of Barton's experiments. Table IV gives the lipolytic activity of our preparation at the acid concentrations used by Barton and for comparison his results obtained under similar conditions.

TABLE IV.

### EFFECT OF VARIOUS CONCENTRATIONS OF HYDROCHLORIC ACID ON CASTOR BEAN LIPASE IN HYDROLYZING OLIVE OIL.

In each experiment 0.2 g. of lipase powder, 0.3 cc. of olive oil and 25 cc. of the acid called for were mixed and incubated at 38° for 24 hours.

Concentration HCl added, %.	Amount of Hydrolysis Produced in Terms of 0.1 N NaOH. Cc.	As found by Barton. Cc.
0.0	0.7	0.2
0.1	0.8	2.0
0.2	0.7	1.2
0.3	0.5	1.1
0.4	0.6	1.3
0.5	0.7	1.6
0.6	0.5	-0.8
0.7	0.5	-0.8
0.8	0.5	-0.1
0.9	0.5	-0.5
1.0	0.5	-0.5

It occurred to us that Barton overstepped the optimum acidity in the lowest acidity, *viz.*, 0.1% of hydrochloric acid, that he used, since in his most active mixtures the amount of fat hydrolysis was very low. Accordingly we made the following experiment to find the effect of varying the concentration of acid between 0.0 and 0.1%. At the same time we

made another series of tests in which we added the same *strengths* of acid but used much smaller volumes. The following table shows the results.

TABLE V.

EFFECT OF VARIOUS CONCENTRATIONS OF HYDROCHLORIC ACID ON CASTOR BEAN LIPASE IN HYDROLYZING OLIVE OIL.

In Series A 0.2 g. of lipase powder, 0.3 cc. of olive oil and 25 cc. of acid were mixed as described by Barton. In Series B, 0.1 g. of lipase, 1.0 g. of olive oil and 0.6 cc. of acid were mixed. The essential difference in the two series is the *amount* of acid used.

Extent of Fat Hydrolysis.					
Series A.			Series. B.		
HCl Added.	0.1 N NaOH		0.1 N NaOH		
%.	Cc.	%.	Cc.	%.	Cc.
0.00	0.7	7	1.0		3
0.02	7.4	77	2.2		6
0.04	3.9	43	16.5		49
0.06	1.1	12	18.2		54
0.08	0.7	7	24.6		73
0.10	0.8	8	24.6		73
0.12	0.6	6	27.2		79
0.14	0.3	3	30.6		90
1.16	0.1	1	29.7		88
0.18	0.3	3	28.3		84
0.20	0.3	3	27.6		81

Table V shows that whether large or small volumes of acid are used the enzyme shows its maximum activity at a certain concentration and then falls off, rapidly when the volume of acid is large and slowly when it is small. At a concentration of hydrochloric acid of 0.1% in Series A there was practically no digestion. The slight hydrolysis indicated is probably without significance and within the limit of experimental error. It must be remembered that the amount of fat used in this series was small, only 0.3 cc., and the necessary corrections for blanks, etc., were relatively large. It is to be expected that the proteins and salts of the lipase powder would show a buffer effect, and hence that the actual concentration of acid in two tubes containing equal amounts of lipase material to which different volumes of the same strength acid had been added would be different. From Table V it appears that the optimum activity in Series A is about 0.02% of hydrochloric acid, while in Series B the optimum concentration is at 0.14. It was suspected that the actual hydrogen-ion concentrations in these two mixtures were about the same. A determination was made by the colorimetric method of Clark and Lubs<sup>9</sup> as follows. Lipase powder and hydrochloric acid were mixed in the following proportions: (1) 0.2 g. of lipase to 25 cc. of 0.02% hydrochloric acid and (2) 0.1 g. of lipase to 0.6 cc. of 0.14% hydrochloric acid. The mixtures were allowed to stand a few minutes, filtered and the hydrogen-ion concentration of the filtrate determined. Mixture 1 had a hydrogen-ion concentration of  $1.8 \times 10^{-5}$ ;

<sup>9</sup> Clark and Lubs, *J. Bact.*, 2, 1 (1917).

# CASTOR BEAN LIPASE.

Mixture 2,  $0.9 \times 10^{-5}$ . The optimum acidity for castor bean lipase activity, therefore, is close to  $C_{H+} 1 \times 10^{-5}$ . This is about the same as that found for gastric lipase by Davidsohn,<sup>10</sup> viz.,  $10^{-4}$  to  $10^{-5}$ . When organic acids, that ionize comparatively little, are used less care need be taken to adjusting the amount of acid to the enzyme. Both acetic and lactic acids can be used with good results over a fairly wide range of percentage concentration.

## The Action of Castor Bean Lipase on Hard Fats.

Fats with high melting points, obviously, do not form emulsions with lipase material and water; hence it is not surprising that they show a low rate of hydrolysis. In order to overcome this difficulty we introduced various fat solvents into the digestion mixtures in the hope of getting better physical contact between enzyme and substrate and thus accelerating hydrolysis. Paraffine oil and ethyl ether were unsatisfactory, comparatively little digestion occurring when either was present. Petroleum ether can be added to advantage in the hydrolysis of an oil by lipase and with marked effect in the hydrolysis of a hard fat. Table VI shows the results obtained with and without petroleum ether.

TABLE VI.

EFFECT OF PETROLEUM ETHER ON THE HYDROLYSIS OF FATS BY CASTOR BEAN LIPASE. The proportions used in each digestion were 0.1 g. of lipase powder, 0.2 g. of fat and 0.6 cc. of 0.1 *N* acetic acid. One cc. of petroleum ether was added to the mixtures containing ether.

Duration of Experiment. Hours.	Olive Oil.		Tallow.	
	Cc. of 0.1 <i>N</i> NaOH. Without ether.	With ether.	Cc. of 0.1 <i>N</i> NaOH. Without ether.	With ether.
24	5.1	5.8	0.2	6.5
48	5.8	5.8	0.2	6.6
72	5.8	5.8	0.2	6.6

## Summary.

A satisfactory method of preparing lipase material from castor beans is to extract the crushed, hull-free kernels with petroleum ether.

The lipase zymogen of castor beans appears to be somewhat soluble in fats or in a mixture of fat and ethyl ether. It is insoluble in ethyl ether in the absence of fats.

Lipase zymogen is activated by acid. The active enzyme is unstable and rapidly destroyed in an acid medium in the absence of fats. In the presence of fats the enzyme shows much greater stability.

The optimum hydrogen-ion concentration for castor bean lipase activity is about  $1 \times 10^{-5}$ . As acidity increases above this point lipolytic activity falls off. At a hydrogen-ion concentration of about  $1 \times 10^{-3}$  activity stops entirely.

<sup>10</sup> Davidsohn, *Biochem. Z.*, 49, 249 (1913).

Petroleum ether added to a mixture of a hard fat, acid, water and castor bean lipase accelerates hydrolysis to a great extent. The hydrolysis of oils is similarly somewhat hastened.

## RESEARCHES ON PYRIMIDINES. XCII. NEW METHODS OF IDENTIFYING THE PYRIMIDINE, THYMINE.

BY TREAT B. JOHNSON AND OSKAR BAUDISCH.

Received August 29, 1921.

Of the three pyrimidines which have so far been found as products of hydrolysis of nucleic acids only two, namely, uracil (I) and cytosine (II), can be identified by means of characteristic color reactions. Wheeler and Johnson<sup>1</sup> developed a delicate test for these two pyrimidines which

(I).

(II).

(III).

is applied by first oxidizing them in aqueous solution with bromine and then treating the resulting solution with an excess of barium hydroxide. A characteristic purple color develops under such conditions, due to the formation of the barium salt of dialuric acid, which permits of the identification of these two pyrimidines when present in very small quantities. Thymine (III) or any pyrimidine of this type containing alkyl groups in Positions 4 or 5 of the pyrimidine ring fails to respond to this characteristic test.

On account of the important rôle which thymine plays in the chemical processes operating during the growth and destruction of the living cell, it is very important to have available also a characteristic color reaction for the detection of this pyrimidine. A color test which would permit the identification of thymine in the presence of uracil, cytosine and sugar would be of the greatest value in any investigation dealing with the constitution of nucleic acids. The basic properties of cytosine permit its separation from uracil and thymine, but up to the present time we have had no method of identifying small quantities of thymine in the presence of uracil and sugars.

We are able to announce in this paper the discovery of color reactions which are as characteristic for thymine as the dialuric acid reaction is for the identification of the pyrimidine uracil. We find that the thymine molecule is completely destroyed at ordinary temperature, when subjected

<sup>1</sup> Wheeler and Johnson, *J. Biol. Chem.*, 3, 183 (1907).

in aqueous solution to the oxidizing and reducing action of the system, ferrous sulfate plus sodium hydrogen carbonate plus air,<sup>2</sup> with cleavage of the pyrimidine ring and formation of pyruvic acid, acetol, urea and formic acid. The urea is easily identified by the properties and melting point of its characteristic grouping with xanthydrol,<sup>3</sup> while the formic acid is recognized by its reducing action on silver salts.

For the detection of the two remaining products of oxidation namely, pyruvic acid and acetol, we have made use of reactions already described in the chemical literature, and it is on two specific reactions that we base our color tests, which we now bring forward as an indirect proof of the presence of thymine. The identification of pyruvic acid as a product of oxidation of thymine is shown conclusively by its behavior towards *o*-nitro-benzaldehyde in alkaline solution when, as is well known, they interact to form the dye indigo.<sup>4</sup> The color reaction of pyruvic acid with sodium nitroprusside cannot be utilized in our work as a direct test for this reagent on account of the presence of urea, which we find interacts also with the nitroprusside giving a similar highly colored solution. For the detection of acetol we utilize the very susceptible and specific reaction first developed by Baudisch,<sup>5</sup> who has shown that this ketone alcohol interacts smoothly in alkaline solution with *o*-amino-benzaldehyde with formation of 3-oxyquinaldine. Both of these reactions are extremely sensitive and applicable in very great dilution.

These reactions, which are applicable for the detection of these two aliphatic combinations resulting by oxidation of thymine, serve, therefore, for the indirect identification of this pyrimidine. The discussion of the mechanism of the change whereby thymine undergoes destructive oxidation is reserved for a future paper. At present we may represent this transformation as follows.

The discovery that the pyrimidine ring in such combinations as uracil, cytosine and thymine may be destroyed by oxidation at such low temperature in the presence of iron salts, and the identification of pyruvic acid and acetol as normal products of oxidation of thymine are new facts of the greatest biochemical interest in that they reveal possible fundamental chemical changes which the pyrimidine ring actually undergoes in the normal metabolic transformations of the cell.

<sup>5</sup> Baudisch, *Biochem. Z.*, 89, 279 (1918).

### Experimental Part.

While it has been shown that the oxidation of uracil, cytosine and thymine leads to products of physiological interest, a description of these experiments and the discussion of the theory of these oxidations will be deferred for publication in a later paper. At this time we shall confine ourselves to the practical method of applying our new color reactions for the detection of thymine in the presence of other pyrimidines.

A description of a single experiment will suffice to reveal the interesting behavior of thymine when subjected to the oxidizing action of the system, ferrous sulfate plus sodium hydrogen carbonate plus air. Two and six-tenths g. of recrystallized thymine was dissolved in about 100 cc. of hot water and this solution then poured into one of 200 g. of sodium hydrogen carbonate dissolved in 2 liters of water. A 5-liter flask serves best for this operation. To this solution of thymine and bicarbonate is then added 100 g. of crystallized ferrous sulfate dissolved in 500 cc. of water, and the resulting mixture then agitated violently. Colorless iron hydrogen carbonate precipitates at once and will remain in this condition if protected from the air. On agitation of the solution, however, with exposure to the air this carbonate precipitate gradually assumes a green color, due to the absorption of oxygen from the air, with formation of an unstable peroxide. One proceeds to agitate the mixture thoroughly when the oxidation of the thymine takes place immediately and the greenish-gray color of the carbonate precipitate disappears slowly and the carbonate finally assumes a brownish color and the appearance of iron hydroxide. This oxidation and change in the carbonate take about  $\frac{3}{4}$  hour. The mixture is now poured into a filtering jar and allowed to stand overnight when a clear colorless solution is obtained and the iron hydroxide deposits as a dense layer on the bottom of the jar. This clear solution is not characterized by any special odor and is colorless.

The final change in the process of oxidation is brought about by transferring the supernatant liquid to a large evaporating dish and heating the solution on a steam-bath. Hydrolysis takes place under these conditions and the solution acquires an odor characteristic of an alkaline sugar solution when heated. After heating long enough to bring about the above change, 100 to 200 cc. of the clear solution is evaporated to dryness; the residue dissolved again in distilled water and the evaporation repeated. Pyruvic acid is not volatile with steam while acetol vaporizes easily. The dry residue is then dissolved in a small volume of water and the indigo test for pyruvic acid applied as follows: to 5 to 10 cc. of the cold solution are added a few drops of *o*-nitro-benzaldehyde, and the mixture is shaken with chloroform after the addition of 1 to 2 cc. of conc. potassium hydroxide solution. On shaking, the indigo forms immediately and dissolves in the chloroform giving a characteristic blue solution. The formation of indigo

is hastened by warming the solution to be tested and agitating this with the nitro-benzaldehyde until an emulsion is formed and then shaking with chloroform and alkali. Under these conditions a deep blue chloroform solution is obtained and the reaction is so delicate that this characteristic blue color can be obtained easily with solutions representing as low as 2 to 5 mg. of thymine.

In order to apply successfully the test for acetol the remainder of the original thymine solution is subjected to distillation by boiling over a free flame. The distillate at first possesses no reducing properties and is odorless, but as the distillation is continued the characteristic sugar smell develops and finally the distillate acquires the property of reducing Fehling's solution and also ammoniacal silver solution. In order to test for acetol the total distillate is combined with a few drops of *o*-amino-benzaldehyde, potassium hydroxide solution is added until the mixture is distinctly alkaline, and the solution is finally boiled for a few minutes in a beaker. After cooling, the solution is acidified directly with dil. hydrochloric acid, and then made it alkaline again with sodium hydrogen carbonate solution when a characteristic blue fluorescence develops as a result of the formation of 3-oxyquinaldine. For a more exact determination of the acetol the sodium hydrogen carbonate solution is extracted with ether, the ether solution carefully dried and finally distilled when nearly colorless needles are obtained, which have the correct melting point and possess the characteristic properties of 3-oxyquinaldine. An alcoholic solution of the quinaldine develops after dilution with water a deep blue fluorescence, and on adding an alcoholic solution of iron chloride the characteristic deep red complex iron salt of 3-oxyquinaldine is obtained. This red salt is destroyed immediately by addition of acid.

The formation of 3-oxyquinaldine from acetol and *o*-amino-benzaldehyde is a reaction which was first discovered by Baudisch<sup>5</sup> and is one which is specific for this ketone alcohol. The formation of the quinaldine in the distillate of the oxidized thymine proves the formation of acetol as a product of oxidation of this pyrimidine, which is a discovery of the greatest biochemical interest.

Uracil behaves in an entirely different manner from thymine towards the system ferrous sulfate plus sodium hydrogen carbonate plus air. Both pyrimidines are oxidized apparently in a similar manner, but uracil cannot lead to the production of pyruvic acid on account of the absence of a methyl group in Position 5 of the pyrimidine ring. Consequently according to our procedure uracil and thymine can be tested for in the presence of each other, which has not been possible hitherto.<sup>6</sup> In fact, we have been able to demonstrate that it is possible to detect thymine easily in the presence of uracil and cytosine by application of our method. Mixtures of 0.5 g.

<sup>5</sup> See *J. Biol. Chem.*, **4**, 407 (1908).

each of uracil and cytosine and also of uracil and cytosine with small quantities of thymine (0.15 g.) were oxidized according to the procedure described above, and the test for thymine applied. In no case were we able to obtain the characteristic blue color reactions except in those mixtures into which thymine had been introduced.

In this paper we have recorded only the qualitative characteristics of our colorimetric test for the pyrimidine, *thymine*. When the pyrimidine has been prepared in quantity and, therefore, sufficient material is available for research this oxidation reaction will be investigated more carefully and from a quantitative point of view.

Our work to date shows that the system, ferrous sulfate plus sodium hydrogen carbonate plus air, is characterized by its specific oxidizing and reducing action, which may be utilized for bringing about fundamental changes in organic combinations of biochemical interest. The writers are now engaged in the study of several of these transformations and will extend the investigation to new fields of research in which it is anticipated that the ferrous hydroxide-peroxide reagent will reveal still further new transformations of biochemical interest.<sup>7</sup>

### Summary.

1. It has been shown that ferrous hydroxide-peroxide is a sufficiently strong oxidizing agent to destroy the pyrimidine ring at a very low temperature.

2. Uracil, thymine and cytosine are completely destroyed by interaction with this reagent leading to the formation of products which are easily hydrolyzed to urea and aliphatic combinations.

3. In the case of thymine it has been definitely established that pyruvic acid and acetol are normal products of oxidation. These compounds can be identified easily by characteristic color reactions, which serve indirectly as reliable tests for thymine.

NEW HAVEN, CONNECTICUT.

---

<sup>7</sup> Our methods of testing for uracil, cytosine and thymine will find immediate practical application in the study of constitution of nucleic acids, and in the research on *tubercle bacillus* now in progress in this laboratory (T. B. Johnson).

# THE C<sub>4</sub>-SACCHARINIC ACIDS. II. THE PREPARATION AND RESOLUTION OF dl-1,3-DIHYDROXY-BUTYRIC ACID. SOME DERIVATIVES OF THE OPTICALLY-ACTIVE ACIDS.

By J. W. E. GLATTFELD AND FRANK V. SANDER.<sup>1</sup>

Received August 29, 1921.

The first two C<sub>4</sub>-saccharinic acids to be prepared in this laboratory and studied in detail, were the two optically-active 2,3-dihydroxy-butyric acids.<sup>2</sup> The present paper is a report of the results of a similar study of the optically-active 1,3-dihydroxy-butyric acids. The object of this work is to provide material with which to study the properties of the saccharinic acids, to find means of identifying the individual acids, and to devise methods for separating them from each other in such mixtures as are obtained when sugars are treated with alkalies.

The acid under consideration has been obtained in its inactive form by Nef<sup>3</sup> and his students in the course of their work on the effect of alkalies on the various sugars. Nef not only obtained the *dl*-acid but resolved it into the active components and proved the configuration of the *d*-acid

to be CH<sub>2</sub>.OH.C.C.-COOH by oxidation to *d*-malic acid. He also gives

some information as to constants of the brucine salt, phenylhydrazide and lactone of the *dl*-acid, as well as the brucine salt, quinine salt and lactone of the *d*-acid and the brucine salt of the *l*-acid. His study of the *l*-acid was apparently very superficial.

The *dl*-acid and the *dl*-calcium salt have been prepared also by Raske<sup>4</sup> in the course of his investigation of the action of cyanides on chlorinated aldehydes. He obtained from 2-chloro-propionaldehyde and cyanides, 1-oxy-3-chloro-butyric acid which was converted into 1,3-dihydroxy-butyric acid when boiled with water.

The above is a summary of all the work that has been published on the acid under consideration. Neither of the methods by which the acid had been prepared was considered suitable for the object of the work below. It was therefore prepared, by a method similar to Raske's, from 2-hydroxy-propionaldehyde by the addition of hydrogen cyanide and subsequent

<sup>1</sup> The dissertation of which this paper is a condensation was presented by Frank V. Sander as part fulfilment of the requirements for the degree of Doctor of Philosophy in the University of Chicago. The original dissertation is on file in the University of Chicago Library.

<sup>3</sup> Nef, *Ann.*, **376**, 1-120 (1910). Upson, *Am. Chem. J.*, **45**, 458 (1911).

<sup>4</sup> Raske, *Ber.*, **45**, 725 (1912).

hydrolysis of the nitrile. In the course of this study, Nef's entire work on this acid was repeated and the study of the *l*-acid completed.

### Experimental Part.

The starting material for the synthesis was acrolein which had been prepared from dry glycerin and anhydrous magnesium sulfate, according to the method of Witzemann.<sup>5</sup> The crude acrolein was introduced into a steel cylinder with 4 volumes of water<sup>6</sup> and heated in a boiling water-bath for 20 hours. The solution was then subjected to complete distillation at 60° and 14 mm. in one operation by siphoning liquid into the distilling flask as fast as water distilled. The gummy residue was then distilled from an oil-bath at a low temperature and pressure. It was found that a much higher yield could be obtained when the total quantity of gummy residue was subjected to distillation in one operation than if divided into 4 portions, as suggested by Nef, and each portion subjected to distillation separately. The best results were obtained when the temperature of the oil-bath was kept about 10° above that of the vapor in the flask, and it was only by very slow and careful distillation that maximum yields could be obtained from the crude aldehyde. The yield of redistilled aldehyde of boiling range 80–86° at 14 mm. from 400 cc. of crude acrolein, averaged 95 g. The pure aldehyde can be redistilled with practically no decomposition and may be considered a fairly stable substance.

The pure aldehyde dissolved in water was treated with hydrogen cyanide, etc., in the usual manner. The hydrolysis of the nitrile was effected with conc. hydrochloric acid. The black gum which remained after subjecting the reaction mixture to complete distillation was extracted with boiling ethyl acetate and with hot ether. The acid recovered from these solutions was again extracted with hot ether. The average yield of the clear, yellow, mobile acid recovered from the ether was about 70% of the amount calculated from the pure aldehyde. The crude acid was converted into the calcium salt by means of calcium carbonate, and trituration with alcohol, etc. From 92 g. of crude acid there was obtained an average yield of 92 g. of dry powdery salt.

*Pure dl-Acid.*—The acid gum obtained from the calcium salt by means of oxalic acid, etc., was first dried as completely as possible in a boiling water-bath at 14 mm. A glycerine-bath was then substituted for the water-bath and the water pump was replaced by an oil pump. A perfectly clear, mobile, and in some cases odorless, liquid distilled over, boiling point at 4 mm. 104°, and at 3 mm. 102°. The distillate was titrated with 0.1 *N* sodium hydroxide with the following results.

I	0.2462	0.05	24.18	24.14
II	0.2832	0.05	27.90	27.77

It is evident that the liquid was practically pure lactone. It is soluble in about 12 parts of warm ether.

Five g. of the lactone, with phenyl hydrazine, etc., gave 8.53 g. of crystals, m. p. 130°. The melting point was unchanged when the substance was recrystallized. As Nef reports a melting point of 130° for his *dl*-hydrazide from *l*-arabinose, these two substances were evidently identical.

**The Resolution of the *dl*-1,3-Dihydroxy-butyric Acid.**—To 36 g. of the acid lactone which had a boiling point of 102° at 3 mm., was added, in one liter of water, 165 g. of brucine. After the usual procedure<sup>8</sup> 182 g. of crude brucine salts was obtained. A sample of this crude salt after a treatment with benzene to remove any free brucine and drying to constant weight over sulfuric acid *in vacuo*, was found to have a specific rotation of -26.73°, *i. e.*, 1 g. in 24 g. of water at approximately 20° gave  $\alpha = -2.16^\circ$  in a 2 dcm. tube; sp. gr. 1.010.

The *dl*-brucine salt was now dissolved in twice its weight of hot water. The solution was allowed to stand overnight during which time crystals were deposited (Crop I from water, see below) which were removed by filtration. The filtrate was concentrated until the ratio of water to salt was again 2:1. This solution again yielded a crop of crystals. When no more crystals could be obtained in this way from water, the solution was subjected to complete distillation at 60° and 14 mm. and the residue dissolved in 10 parts of boiling absolute alcohol. When the solution had cooled, the crystals deposited (Crop I from alcohol, see below) were removed by filtration, and the filtrate concentrated until the ratio of salt to alcohol again was 1:10. This process was continued until no more crystals could be obtained. The following table shows the results. The crystals were dried to constant weight *in vacuo* over sulfuric acid, and in each case a 1g. sample was dissolved in 24 g. of water. The specific gravity was found to be 1.010 and readings were taken in a 2dcm tube at approximately 20°.

Crops I, II and III from water were united and recrystallized from 2 parts of water. This process gave 65 g. of crystals. The specific rotation was -20.79. Six subsequent recrystallizations from 2 parts of water gave crops each of which had a specific rotation of -20.79°. This indicates that the substance was the pure brucine salt of one of the optical components of the *dl*-acid. The melting point of this brucine salt was 169°.

FROM WATER.	Parts of water used.	Weight. G.	$\alpha$ . Observed.	$[\alpha]_D^{20}$ .
I	2	49	$-1.68^\circ$	$-20.79^\circ$
II	2	8	$-1.71^\circ$	$-21.16^\circ$
III	1	20	$-1.72^\circ$	$-21.28^\circ$
Residue		104		
FROM ABSOLUTE ALCOHOL.	Parts of alcohol used.	Weight. G.	$\alpha$ . Observed.	$[\alpha]_D^{20}$ .
I	10	75	$-2.77^\circ$	$-34.28^\circ$
II	10	18	$-3.09^\circ$	$-38.23^\circ$
III	10	1	$-3.18^\circ$	$-39.35^\circ$
Residue		9.2		

Crops I, II and III from alcohol were united and recrystallized from 10 parts of alcohol, and thus 78 g. of crystals was obtained with a specific rotation of  $-32.67^\circ$ . Six subsequent recrystallizations from 10 parts of absolute alcohol gave crops each of which had a specific rotation of  $-32.67^\circ$ . This indicates that the substance was the pure brucine salt of the other optical component of the *dl*-acid. The melting point of this acid was  $169^\circ$ .

In all cases of recrystallization from alcohol, the mother liquors when concentrated *in vacuo* at  $60^\circ$  yielded second crops of crystals, the specific rotations of which were much higher than  $-32.67^\circ$ , the invariable rotation of the first crops. That this was due to free brucine was shown as follows. When separate samples from Crops I, II and III, from alcohol,  $[\alpha]_D^{20}$   $-34.28$ ,  $-38.23$ ,  $-39.35$ , respectively, were refluxed for 2 hours with benzene, the specific rotations of the extracted brucine salts fell in each case to  $-32.67^\circ$  and the benzene was shown to contain brucines. Hydrolysis was not observed in the case of recrystallization of the pure brucine salt of low rotation from water. This salt is apparently perfectly stable in water solution. Furthermore the specific rotation of this salt was not changed after it had been boiled for 2 hours with benzene under a reflux condenser.

**The Optically-active 1,3-Dihydroxy-butyric Acids.**—The active acids were obtained by the usual method<sup>9</sup> from the pure brucine salts by treatment with barium hydroxide, etc. The crude acid was distilled at 3 mm. and the distillate in each case was a perfectly colorless, transparent, mobile, odorless liquid with a boiling point of  $96^\circ$ . The yield from 100 g. of brucine salt  $[\alpha]_D^{20} -20.79^\circ$ , was 18.0 g. and from 100 g. of brucine salt  $[\alpha]_D^{20} -32.67^\circ$ , was 17.8 g.

The specific rotations of the two acids were now determined with the following results. In each case an exactly 4% solution was used in a 2dm. tube. The specific gravity was 1.010 and observations were made at approximately  $20^\circ$ .

The figures show that equilibrium between free acid and lactone was reached in water solution at ordinary temperatures in 7 days. Experi-

II.....	0.2001	0.05	19.48	19.62

The above results show that the acids were practically entirely in the form of lactone.

**Proof of Configuration of the Optically-active Acids.**—Although Nef<sup>10</sup> had already proved the configuration of the acid of positive rotation, which he obtained from *l*-arbinose, by oxidizing it to *d*-malic acid, his work was repeated and the acid of negative rotation also oxidized. The procedure outlined by Glattfeld and Miller in the first paper,<sup>2</sup> was followed. In each case 5 g. of the optically-active acid was oxidized, and the experimental data thus obtained are tabulated below. An exactly 4% solution was observed in a 2cm. tube at approximately  $20^\circ$ . The specific gravity was determined as 1.010.

II.....	0.3893	29.21	29.05

When natural or *l*-malic acid was purified in the same way as the acid obtained above by the oxidation of the dihydroxy-butyric acid of negative

<sup>10</sup> Nef, *Ann.*, 376, 36 (1910).

rotation, it was found to have a specific rotation of  $-3.34^\circ$  and a melting point of  $101^\circ$ . These constants are practically the same as those of the crystalline acid from the oxidation of the dihydroxy-butyric acid of negative rotation. That the two acids were identical was finally shown by a mixed-melting-point determination. A mixture of the 2 acids melted at  $101^\circ$ .

The above facts show that the acid having  $[\alpha]_D^{20} - 14.86^\circ$  gives natural or *l*-malic acid which has the following configuration, as was shown by Fischer.<sup>11</sup>

Of the two 1,3-dihydroxy-butyric acids only the one with the configuration I (above) can give *l*-malic acid. This must then be the configuration of the dihydroxy-butyric acid  $[\alpha]_D^{20} - 14.86^\circ$  and it must be called *l*-1,3-dihydroxy-butyric acid. In the same way Configuration II (above) must be the configuration of the acid  $[\alpha]_D^{20} + 14.97$  since it gives by oxidation *d*-malic acid, and it must be called *d*-1,3-dihydroxy-butyric acid

### Some Derivatives of the Active Acids.

*The Strychnine Salts.*—The strychnine salts were obtained as well defined crystals from alcohol, but seemed to be hydrolyzed quickly by water.

*The Quinine Salts.*—The quinine salts were made from the pure *d*- and *l*-acids in the usual manner except that the solutions were extracted with chloroform instead of benzene to remove free quinine. The quinine salt of the *d*-acid crystallized from 2 parts of absolute alcohol and the salt of the *l*-acid from 4 parts of absolute alcohol. Thus the solubilities of these 2 salts are the reverse of those of the brucine salts, a fact which may be of value in some cases of separation. The following constants were determined.

	Quinine salt.	$\alpha$ . Observed.	$[\alpha]_D^{20}$ .	M. p. ° C.
(a)	<i>d</i> -acid	$-4.30^\circ$	$-106.4^\circ$	149
(b)	<i>l</i> -acid	$-9.93^\circ$	$-122.9^\circ$	149

(a) 0.3000 g. present in 7.5 g. of water. The angle of rotation was observed in a 1dcm. tube at approximately  $20^\circ$ ; sp. gr. taken as 1.010.

(b) 1.000 g. present in 25.00 g. of water. The angle of rotation was observed in a 2dcm. tube at approximately  $20^\circ$ ; sp. gr. taken as 1.010.

*The Calcium Salts.*—The calcium salts of the pure *d*- and *l*-acids were

<sup>11</sup> Fischer, *Ber.*, 29, 1378 (1896).

made. After treatment with excess calcium carbonate, filtration, and complete distillation of the clear filtrate *in vacuo*, a solid porous white mass was obtained, whereas with the *dl*-acid a clear yellow gum was obtained at this point. The crude salts were recrystallized from water. When 2 parts of water were used a moist pliable mass of interwoven needle-like crystals was obtained, while in 3 parts of water very few crystals were formed.

From 5 g. of *d*-1,3-dihydroxy-butyric acid, there was obtained from water 5.57 g. of a beautifully crystalline salt which after several recrystallizations from 2 parts of water gave a constant specific rotation of  $+17.08^\circ$ , *i. e.*, an exactly 4% aqueous solution in a 1dcm. tube at approximately  $20^\circ$  gave  $\alpha + 0.69^\circ$ ; sp. gr. taken as 1.010. This salt decomposes when heated at  $220$ – $225^\circ$ .

The calcium salt of the *l*-acid was made in exactly the same way as that of the *d*-acid. This salt was made twice from the lactones of  $[\alpha]_D^{20} -20.91^\circ$  and  $-20.05$ , the rotation of each lactone being taken after 5 minutes in solution. The first crops from 2.5 parts of water had specific rotations of  $-8.66^\circ$  and  $-3.80$ . Evidently these crops were not the normal salts of the acid.<sup>12</sup> The filtrates from these first crops of crystals were concentrated and the residues dried completely at  $100^\circ$  and 14 mm. The gummy residues were then made crystalline by trituration with absolute alcohol. The salts so obtained were apparently the normal salts of the acid as was shown by their specific rotations  $-17.33^\circ$  and  $-17.01^\circ$ , respectively.

An analysis of the calcium salts of the *d*- and *l*-acids was made. The salts were ignited to constant weight in a platinum crucible with the following results.

Calcium salt. Rotation.	Sample. G.	Constant wt. dried at $100^\circ$ . G.	Loss of water %.	Constant wt. of ash. G.	CaO. %.
$+17.08^\circ$	0.3503	0.3103	11.42	0.0627	17.89
$-17.33^\circ$	0.3169	0.2806	11.45	0.0568	17.92
Calc. for $\text{Ca}(\text{C}_4\text{H}_7\text{O}_4)_2 \cdot 2\text{H}_2\text{O}$			11.46		17.83

The cinchonine and barium salts and the phenylhydrazides of the two pure acids were made but all proved to be gums.

### Summary.

*dl*-1,3-Dihydroxy-butyric acid has been prepared from 2-hydroxy-propionaldehyde. The resolution of the *dl*-acid, by means of brucine, into the optical components is reported. Configurations are assigned to the two forms of the acid and proofs of the correctness of these configurations are given. The following constants for the *d*- and *l*-forms of the acid, and some of the derivatives, are given.

<sup>12</sup> The exact nature of these salts has not been determined. A thorough investigation of the calcium salt formation in these cases will be taken up as soon as opportunity offers.

## THE PREPARATION OF OPTICALLY-ACTIVE HYDRAZINES.

II. THE PREPARATION OF *dl*-*p*-SECONDARY-BUTYL-PHENYLHYDRAZINE. THE RESOLUTION OF *dl*-*p*-SECONDARY-BUTYL-ANILINE.By J. W. E. GLATTFELD AND EDGAR WERTHEIM.<sup>1</sup>

Received August 29, 1921.

As stated in the first paper<sup>2</sup> of this series these attempts to prepare some optically-active phenylhydrazines have been undertaken in order to supply another set of reagents to supplement the alkaloids in the resolution of such *dl*-hydroxy acids as the saccharinic acids.<sup>3</sup> Furthermore the hope has been entertained that methods of preparation might be found which would make some of the optically-active hydrazines much less expensive than the alkaloids ordinarily used. In the previous attempt only the *dl*-*p*-trimethylethyl-phenylhydrazine was prepared, such attempts as were made to obtain one of the active forms having failed. In the work reported below it was again found impossible in the time at hand to isolate the active forms of the hydrazine prepared (*sec*.-butyl-phenylhydrazine) although the hydrazine was obtained in the *dl* form and the active forms of the corresponding aniline were isolated. In the light of our work up to the present time, it does not seem impossible ultimately to succeed in obtaining some of the active phenylhydrazines and our attempts will therefore continue. In the present paper we report as briefly as seems possible those results of our work that appear to us to be of some general interest or importance.

The plan for the preparation of the optically-active *p*-*sec*.-butyl-phenylhydrazines included first the preparation of *dl*-*sec*.-butyl-aniline, then the resolution of this compound into the two optical isomers, and finally the preparation from these, of the active phenylhydrazines.

In order to prepare *dl*-*p*-*sec*.-butyl-aniline it was necessary first to pre-

<sup>1</sup> The dissertation of which this paper is a condensation was presented by E. Wertheim as part fulfillment of the requirements for the degree of Doctor of Philosophy in the University of Chicago. The original dissertation is on file in the University library.

<sup>3</sup> Glattfeld and Miller, *ibid.*, **42**, 2314 (1920).

pare and in the order named, the following compounds: (1) "methopropenyl benzene" (1-phenyl-1-methyl-2-methyl-ethylene); (2) *dl-sec.*-butylbenzene; (3) *dl-p*-nitro-*sec.*-butylbenzene. The first two of these compounds are described in the literature,<sup>4</sup> and the methods there set forth have been modified somewhat in the unpublished work of R. J. Williams<sup>5</sup> and A. F. Hardman.<sup>6</sup> The third compound was first prepared by Williams,<sup>5</sup> and his work was repeated and extended by Hardman.<sup>6</sup>

In the present paper the preparation of these three compounds will not be described in detail; only departures from published work and from the ordinary course of synthesis will be noted.<sup>7</sup>

*dl-p-sec.*-Butyl-aniline has recently been prepared by Reilly and Hickinbottom<sup>8</sup> in the course of their investigations in rearrangements of the alkyl-aryl amines. They heated *sec.*-butyl alcohol, aniline and zinc chloride in an autoclave at a high temperature and isolated this compound, as well as other amines, from the reaction mixture. As they prepared and analyzed several derivatives of the compound, their work will be referred to again.

### Experimental Part.

"Methopropenyl benzene" was prepared by the method of Grignard, from acetophenone, ethyl bromide and magnesium turnings. The acetophenone was added to the thoroughly cooled (with ice and salt) and vigorously stirred ether solution of ethylmagnesium bromide and the impure hydrocarbon was obtained by hydrolysis of the reaction product with ice water and, later, dil. sulfuric acid. The product of the reaction consists in large part of methyl-ethyl-phenyl-carbinol. A fact which does not appear to have been noted before is that most of the carbinol can be changed to the olefine by heating to 100° for 20 minutes. Fractions which corresponded to the temperatures *t*-180°, 180-186°, 186-191°, 191-*t*° were taken and dried by means of calcium chloride. Practically the whole of the product after the second fractionation was found in the fraction which had the boiling range 186-191°.

The boiling point of the pure compound is variously reported in the literature. The writer's experience agrees with that of Tiffeneau<sup>4</sup> who gives 186-7° as the boiling point at ordinary pressure. For the purposes of this work the entire fraction 186-191° was used without further treatment for the next step in the synthesis. The best yield of the fraction 186-191° obtained in 12 runs was 82%; the average yield was 73%. These are calculated from the acetophenone used.

For the preparation of *sec.*-butylbenzene, "methopropenyl benzene" was reduced by the use of sodium and moist, but alcohol-free, ether.<sup>5</sup> Freshly cut sodium was dropped through the condenser and into the hydrocarbon which was dissolved in a layer of ether resting upon water. After 75% of the sodium had been introduced, the reduction

<sup>7</sup> Minute details of the procedure followed throughout this work will be found in the complete dissertation of E. Wertheim on file in the University Library, University of Chicago.

<sup>8</sup> Reilly and Hickinbottom, *J. Chem. Soc.*, 117, 120 (1920).

was interrupted, the ether layer separated from the aqueous layer, and the latter twice extracted with ether and then discarded. The reduction was then resumed as above with a fresh water layer. It was found that removing the alkaline water solution at this stage materially increased the yields. The fraction of boiling range 170–180° was then obtained from the ether layer and extracts and was used for the next step in the synthesis. Most of the liquid distilled at 173–4° which is the boiling point of *sec.*-butyl-benzene given in the literature.<sup>9</sup> The best yield obtained in 11 runs was 77%; the average was 67%.

In preparing the *p*-nitro-*sec.*-butyl-benzene the ordinary course of nitration with nitric and sulfuric acids was followed. The temperature of the reaction mixture was kept between 5° and 10°. The nitro compound was obtained by steam distillation, ether extraction of the distillate, etc. The fraction which had a boiling range of 130–140° at 12 mm. was largely *dl-p*-nitro-*sec.*-butyl-benzene.<sup>10</sup> This fraction was redistilled and the part which boiled at 130° at 9 mm. was pure *dl-p*-nitro-*sec.*-butyl-benzene. The best yield in four runs was 63%; the average was 57%.

The reduction of the nitro compound was carried out in the usual manner with conc. hydrochloric acid and granulated tin. The aniline was obtained from the reaction mixture by the addition of sufficient alkali to make it just alkaline (a large excess of alkali is to be avoided<sup>2</sup>), subsequent distillation with steam, extraction of the distillate with ether, etc. The boiling range of the crude compound was 120–130° at 18 mm. Redistillation yielded pure aniline which boiled at 112° at 11 mm. The boiling point at atmospheric pressure is given by Reilly and Hickinbottom<sup>8</sup> as 238°. The acetyl derivative was prepared by the use of acetyl chloride. It was recrystallized from a mixture of water and 95% alcohol and was found to have a melting point of 125–6°. This is the melting point reported by Reilly and Hickinbottom.<sup>8</sup>

The *dl-p-sec.*-butyl-aniline was analyzed in this laboratory by Mr. Williams.<sup>5</sup> The following results are quoted from his paper.

*Analyses.* Subs., 0.1437, 0.2311: CO<sub>2</sub>, 0.4241, 0.6843; H<sub>2</sub>O, 0.1276, 0.2046. Subs., 0.2938, 0.2994: N<sub>2</sub>, 24.65 cc. (20° and 751 mm.), 24.1 cc. (20° and 749 mm.). Calc. for C<sub>10</sub>H<sub>13</sub>N: C, 80.54; H, 10.07; N, 9.39. Found: C, 80.50, 80.75; H, 9.94, 9.90; N, 9.52, 9.11.

The preparation of *p-sec.*-butyl-aniline was also attempted by the Friedel and Crafts reaction, using acetanilide, *sec.*-butyl chloride, and aluminum chloride. The reaction seemed to go quite smoothly and the desired aniline was obtained by hydrolysis, etc., but in small quantity; the largest yield realized was 14%. The aniline had the proper boiling point, and the acetyl derivative had the proper melting point. When mixed with a sample of the acetyl derivative from the aniline made from acetophenone above, there was no depression of the melting point.

### Resolution of *dl-p-sec.*-Butyl-aniline.

Oxymethylene-camphor and bromo-camphor sulfonic acid were first tried as resolving agents for *dl-p-sec.*-butyl-aniline, but with only partial success. Camphor sulfonic acid was found to be a much better reagent. A typical experiment is described below.

*Levo-p-sec.*-butyl-aniline.—Ten g. of the *dl-p-sec.*-butyl-aniline was placed in a beaker and 10 cc. of 30% acetic acid added. To this mixture was added 17 g. (15.5

<sup>9</sup> Klages, *Ber.*, 35, 3509 (1902).

<sup>10</sup> The position of the nitro group as *para* was established in the work of R. J. Williams to which reference has been made. He oxidized the nitro compound with chromic acid to *p*-nitrobenzoic acid, and proved the identity of the latter substance.

g. required theoretically) of camphor sulfonic acid as a fine powder. The mixture was stirred until the acid had dissolved. This took place readily and with the production of a small amount of heat. The beaker was then kept on an electric hot-plate at 100° for 2 hours, or until a considerable part of the acetic acid had evaporated, and the residue was quite thick.

The mass was then allowed to cool, after which it was broken up with a pestle and twice well-washed by decantation with ice-water. The water which adhered was removed as quickly as possible by the use of a Büchner funnel. The moist compound was pressed between filter papers, and then placed in a vacuum desiccator over sulfuric acid. It was generally quite dry in 5 or 6 days. By this treatment the racemate obtained was fairly pure as shown by the following rotations. These rotations are from 5 different preparations of the racemate.<sup>11</sup>

*Rotations.* Subs., 0.9862, 0.9121, 0.5522, 0.2262, 0.2392.  $[\alpha]_D = +25.98, 25.77, 26.11, 25.97, 26.23$ .

The melting point of the dry racemate was 119–120°; it was a light pinkish-yellow powder, and weighed between 17 and 20 g.

The racemic compound was next treated with 50 to 75 cc. of pure ether, and allowed to stand with frequent stirring for about 2 hours. The supernatant liquid changed in this time to a pink color, and the powder became pure white. The mixture was then subjected to filtration by suction, and the white crystals were washed on the filter with dry ether, and then air-dried. The crystals were recrystallized from a mixture of about 5 parts of ethyl acetate to 1 part of acetone, and then had a melting point of 173–4°. A separation had therefore evidently been effected. The sample at this point usually weighed from 5 to 7 g. Rotations in chloroform showed no change after several crystallizations of the same crop from the solvents named above; the value was invariably near to +32.00. The following figures show the results of one such experiment.<sup>12</sup>

Crop.	Weight. G.	Subs. G.	$[\alpha]_D$
1	6.0	0.2740	+31.95
2	3.8	0.2282	+32.32
3	2.2	0.3038	+31.68
4	0.93	0.2305	+31.62

The following figures for a number of samples show the constancy of the rotation after the first crystallization. These are the rotations of 6 different preparations after the ether treatment of the racemate, and one recrystallization from acetone-ethyl acetate mixture of the crystals insoluble in ether.

*Rotations.* Subs., 0.3329, 0.6062, 0.6050, 0.8351, 0.4915, 0.5539  $[\alpha]_D = +31.47, 31.22, 31.76, 31.43, 31.54, 31.41$ .

From these figures it seems fairly certain that one of the pure components has a specific rotation between +31.5 and 32.00. The free aniline was obtained by treating the camphor sulfonic derivative of this specific rotation first with conc. hydrochloric acid, and treating the crystalline hydrochloride obtained with alkali, etc. The aniline was found to have a light yellow color and to boil at 116.5–118° at 15 mm. pressure. A

<sup>11</sup> All the rotations in this work were made, unless otherwise stated, in chloroform solution, in a 2dcm. tube and at room temperature. The solution was in each case made up to a volume of 25 cc. and quickly filtered, after which the readings were taken with the minimum loss of time.

<sup>12</sup> The 2nd crop (3.8 g.) was obtained by recrystallization of the 1st crop (6.0 g.). The 3rd crop (2.2 g.) was obtained by recrystallization of the 2nd crop (3.8 g.), etc.

sample of this aniline when examined in a 0.5dcm. tube gave  $\alpha = -0.26$ . Analysis of samples gave the following results.

Subs., 0.2986, 0.3022:  $\text{CO}_2$ , 0.8832, 0.8932;  $\text{H}_2\text{O}$ , 0.2724, 0.2796. Subs., 0.3386, 0.3422:  $\text{N}_2$ , 29.4 cc. ( $24^\circ$  and 740.5 mm.), 29.5 cc. ( $24.5^\circ$  and 748 mm.). Calc. for  $\text{C}_{10}\text{H}_{13}\text{N}$ : C, 80.54; H, 10.07; N, 9.39. Found: C, 80.67, 80.61; H, 10.14, 10.23; N, 9.49, 9.46.

The acetyl derivative was made by treating the aniline with acetyl chloride, and the resulting crystals were recrystallized from a mixture of water and 95% alcohol. The pure white crystals were found to have a melting point of  $123-4^\circ$ . When the rotation of a sample of 0.5376 g. was taken in chloroform solution, the specific rotation was found to be  $[\alpha]_D^{25} = +0.9301$ .

**Dextro-*p*-sec-Butyl-aniline.**—The dextro-rotatory aniline was obtained from the soluble camphor sulfonic acid derivative left in the filtrates after the crystalline derivative had been removed (see above). This soluble compound remained as a dark-brown or black semi-solid gum after all of the solvent had been removed by evaporation. Solutions were too dark for determination of the rotation.

The gum was first dissolved in sodium-dried ether and separated by filtration from a few crystals of the less soluble isomer which it contained. The ether was next removed by evaporation, and the gum covered with conc. hydrochloric acid and heated to  $100^\circ$  for 5 hours. Excess of sodium hydroxide was then added, and the aniline recovered as usual. The boiling point of the aniline was  $123-5^\circ$  at 20 mm. Part of this sample was placed in a 0.5dcm. tube and gave  $\alpha = +0.26$ . This rotation is equal and opposite to that of the aniline from the crystalline camphor sulfonic compound, and indicates that the sample was probably pure.

An attempt to convert 9.6 g. of the *l*-sec-butyl-aniline into the active phenylhydrazine failed entirely although the procedure under which the *dl*-aniline had been successfully converted into the *dl*-hydrazine (see below) was followed carefully. Furthermore, these conditions failed also in one instance in the making of the *dl*-hydrazine. No reason for these failures can be offered at the present time, but it is hoped that perfect conditions for the conversion will ultimately be found.

### Preparation of *dl*-*p*-sec-Butyl-phenylhydrazine.

This compound was prepared from the corresponding aniline as follows.

The aniline was first treated with conc. hydrochloric acid and diazotized. The addition of the nitrite solution took some time as it was found to be important to keep the temperature of the reaction mixture always below  $0^\circ$ . The diazonium salt solution was poured at once into a cold solution of sodium sulfite, giving a rich red solution, a sample of which was only slightly cloudy after having been boiled for one minute. This solution was then reduced in the usual way by the Fischer method<sup>13</sup> with zinc dust and acetic acid. The reaction mixture was heated nearly to the boiling point during the reduction in order to make sure of completeness of reduction. From the cooled solution the solid sulfonate was separated by filtration.

The *dl*-*p*-sec-butyl-phenylhydrazine sodium sulfonate crystallizes from a water solution in beautiful white plates with a pearly lustre. These are stable in the air for about 2 hours when they darken slightly. After one crystallization from 95% alcohol the crystals were well dried in a vacuum desiccator over sulfuric acid.

<sup>13</sup> Fischer, *Ann.*, 190, 67 (1877).

*Analyses.* Subs., 0.1743, 0.1626: N<sub>2</sub>, 15.4 cc. (19° and 753.4 mm.), 14.8 cc. (21.3° and 754.8 mm.).

Subs., 1.0948, 1.3103: BaSO<sub>4</sub>, 0.9557, 1.1544. Calc. for C<sub>10</sub>H<sub>15</sub>N<sub>2</sub>SO<sub>3</sub>Na: N, 10.53; S, 12.03. Found: N, 10.11, 10.36; S, 11.99, 12.10.

To obtain the hydrochloride of the hydrazine, the sulfonate was covered with conc. hydrochloric acid, and the mixture heated to boiling for 8 hours, during which time fresh acid was supplied as needed. The solid hydrochloride was obtained as a mass of white crystals from the cooled solution. These were treated with sodium hydroxide, etc., to give the hydrazine. The crude hydrazine was subjected to distillation at reduced pressure in an atmosphere of hydrogen and boiled at 145–158° at 16 mm. When redistilled it had a boiling range of 155–7° at 18 mm.

The *dl-p-sec.*-butyl-phenylhydrazine is a thick light-yellow oil when first distilled but soon turns to a maroon color in the air. In sealed tubes it keeps its light yellow color indefinitely.

*Analyses.* Subs., 0.2390, 0.2023: N<sub>2</sub>, 36.5 cc. (22.0° and 738.5 mm.), 31.4 cc. (25.8° and 745 mm.).

Calc. for C<sub>10</sub>H<sub>15</sub>N<sub>2</sub>: N, 17.03. Found: 16.85, 16.99.

Only a small amount of the *dl*-hydrazine was available for a study of derivatives and consequently only a few preliminary tests could be made. It seems to form only gummy derivatives with *d*-glucose and *l*-xylose. With *d*-galactose it apparently forms a crystalline derivative with a melting point of 152–155°. With *l*-arabonic and *d*-gluconic lactone no crystalline derivative could be obtained but there was indication of the formation of a crystalline derivative with *d*-mannonic lactone.

### Summary.

This paper describes the preparation and some of the properties of *dl-p-sec.*-butyl-phenylhydrazine; the preparation of *dl-p-sec.*-butyl-aniline, and the resolution of the latter into the *d* and *l* components. The following physical constants are given.

	Boiling point. ° C.	Pressure. Mm.	$\alpha$ in 0.5dm. tube.
<i>dl</i> -Aniline.....	112	11	
<i>d</i> -Aniline.....	123–5	20	+0.26

## EXPERIMENTAL STUDIES ON CYSTINE.

BY ALICE R. THOMPSON MERRILL.

Received August 29, 1921.

In preparing cystine for biological experiments it is of importance to know the conditions which favor the precipitation of pure cystine.

It has been shown by Mörner,<sup>1</sup> Embden,<sup>2</sup> Abderhalden<sup>3</sup> and others that cystine may be obtained by the acid hydrolysis of horn, wool and other protein substances containing cystine in combination. When the acid solution is neutralized with alkali or brought to weak acidity with acetic acid after neutralization, the cystine precipitates on standing.

Folin<sup>4</sup> adds sodium acetate to the acid solution of cystine using congo red as indicator. The sodium acetate acts as a buffer salt. He states that this method gives satisfactory results but does not give quantitative difections for the method.

The purpose of this investigation was (1) to determine the concentration of hydrogen ion of solutions of cystine which insures maximum precipitation of cystine; (2) to determine the amounts of sodium acetate to add to the hydrolyzed solution of wool in order to obtain the best yields of cystine and (3) to secure data in regard to purification of the crude cystine from the hydrolyzed solutions. The yield of cystine obtained by Folin's method is compared to the yield obtained by earlier methods.

## Experimental Procedure.

The wool used in this investigation was analyzed and found to contain 3.1% sulfur and 11.6% moisture. Two portions of 750 g. each were boiled with 1500 cc. of conc. hydrochloric acid in separate 3-liter flasks with large necks fitted with reflux water condensers. The solutions in the flasks were heated in oil-baths at a temperature of about 115°. In spite of the condensers, hydrogen chloride fumes poured out through the water-cooled tubes during the first part of the hydrolysis and continued to do so until the acid mixture approached the concentration of the acid-water mixture of constant boiling point. The time of hydrolysis was counted from the time at which all the wool was pushed into the hot acid. The hydrolysis was run for 3 hours, when the biuret test became negative.

The solutions on cooling and thorough mixing had a volume of 4065 cc. and an acidity of 6.9 molar strength. Aliquots of 500 cc. representing 188.0 g. of wool were taken and sodium acetate trihydrate crystals added to each aliquot as shown in Table I. The solutions were heated to boiling

<sup>1</sup> Mörner, *Z. physiol. Chem.*, **28**, 595 (1899).

<sup>2</sup> Embden, *ibid.*, **32**, 94 (1900).

<sup>3</sup> Abderhalden, *ibid.*, **52**, 348 (1907).

<sup>4</sup> Folin, *J. Biol. Chem.*, **8**, 9 (1910).

and boiled for 5 minutes with constant stirring. After standing for 3 days the precipitate of crude cystine was filtered by suction, removed, rubbed up with cold water, filtered and washed once on a Büchner funnel. This process was repeated. The undiluted mother liquors were kept in glass-stoppered bottles and the washings kept separately.

The mother liquors on standing for 2 weeks were filtered by suction and the second precipitates washed and filtered as the first were.

The precipitates were air dried, ground to a powder and kept in desiccators until they came to constant weights.

Sulfur was determined in these weighed precipitates by Osborne's peroxide method. Sulfur was also determined in pure cystine by the Carius method and the results compared with those obtained by the fusion method. It was found that the Osborne method gave results from about 0.2 to 0.3% lower than those obtained by the Carius method on cystine containing 26.69% sulfur. Half-gram samples were fused and an aliquot representing 0.1 g. taken for the precipitation of barium sulfate. Great care was taken to determine and subtract the sulfur in reagents used, to insure barium sulfate precipitates from reduction during ignition and to make determinations in duplicate.

In Table I are shown the grams of sulfur in each precipitate of crude cystine as calculated from the analysis; also the percentages of cystine obtained from the wool. It is considered here that the sulfur determined represents cystine sulfur. This assumption seems correct since these precipitates were almost completely soluble in 1.8 *M* (6.5%) hydrochloric acid and fairly insoluble in cold water as is cystine also, and the yield of pure cystine obtained by experiment corresponds closely to the yield indicated by calculations from sulfur as determined in the crude precipitates.

TABLE I.

SULFUR IN CRUDE CYSTINE PRECIPITATES FROM ALIQUOTS REPRESENTING 188 G. OF WOOL.

NaC <sub>2</sub> H <sub>3</sub> O <sub>2</sub> (3H <sub>2</sub> O). G.	(1) S in 1st ppt. G.	(2) S in 2nd ppt. G.	Total S in 1 and 2. G.	Total sulfur in wool. %.	Total cystine in wool calc. from sulfur found. %.
350	0.077	0.615	0.692	0.368	1.379
450	0.648	0.975	1.623	0.865	3.241
500	1.273	0.746	2.019	1.075	4.028
550	1.260	0.705	1.965	1.046	3.919
650	2.048	0.112	2.160	1.150	4.309
750	2.268	0.055	2.323	1.236	4.631
850	1.706	0.093	1.799	0.957	3.586
950	1.976	0.151	2.127	1.132	4.242

It is evident from Table I that 350 g. of sodium acetate trihydrate precipitated only traces of cystine after standing for 3 days, while 550 g. of sodium acetate gave a yield of only a little over  $\frac{1}{2}$  of the cystine given by 650 g. of acetate; 750 g. of salt gave the maximum yield of cystine.

The sulfur in the precipitates obtained from the mother liquors which stood for 2 weeks after the first filtration was greatest in those in which insufficient sodium acetate had been added to secure good yields of cystine in the first precipitation.

The total yield of cystine in the first and second precipitates from the aliquot in which 500 g. of acetate had been added was almost as large as with greater amounts of sodium acetate, but required 2 weeks' standing instead of 3 days.

### Determination of Hydrogen-ion Concentrations.

In order to determine the concentration of the hydrogen ion more accurately in the cystine solutions, a set of buffer solutions was made up. The acetic acid-sodium acetate mixtures of Walpole<sup>5</sup> were used in place of the potassium hydrogen phthalate solutions recommended by Clark and Lubs,<sup>6</sup> as the latter gave a decided drift when determining the hydrogen-ion concentration by the electrometric method, due possibly to reduction occurring. The set of standard solutions of Clark and Lubs<sup>6</sup> was also made up and used with the one exception stated above. The hydrogen-ion concentrations of these standard buffer solutions were determined directly in the solutions using the hydrogen electrode. By use of the indicators listed by Clark and Lubs the standard solutions were compared colorimetrically with the cystine solutions. It was considered inadvisable to determine the hydrogen-ion concentration in the cystine solutions by the electrometric method because of probable reduction by the hydrogen electrodes.

Since the hydrolyzed solutions were colored dark brown they were diluted to 5 times the original volume as recommended by Walpole.<sup>5</sup> Measured amounts of indicator were added to given volumes of cystine solutions and compared with standard solutions containing the same amount of indicator. That the tints might be comparable the standard solutions plus the indicator were superimposed against the dark solution according to the method of Walpole<sup>7</sup> but modified as follows.

**Modified Comparator Used.**—Difficulty was experienced in the use of the comparator of Humitz, Mayer and Ostenberg<sup>8</sup> due to the reflection of the light from the round sides of the glass tubes. It was believed that glass cells with flat sides and fitted together in pairs would give better results. Four flat-sided glass cells generally used with colorimeters were therefore picked out. These cells were 10×35×53 mm. inner dimensions and were placed together in pairs, the broad sides fitted and held together

<sup>5</sup> Walpole, *J. Chem. Soc.*, 105, 2501 (1914).

<sup>6</sup> Clark and Lubs, *J. Biol. Chem.*, 25, 479 (1916).

<sup>7</sup> Walpole, *Biochem. J.*, 5, 207 (1910).

<sup>8</sup> Humitz, Meyer and Ostenberg, *Proc. Soc. Exp. Biol. Med.*, 13, 24 (1915).

by elastic bands. The cells were filled with solutions and superimposed according to the Walpole combination.

The cells were placed on dull black card board, placed before the screen described by Clark and Lubs<sup>9</sup> and lighted by 4 electric bulbs. A dull black card board with vertical rectangular windows cut close together was drawn over the cells and the color of each as seen through the apertures compared. The cells were also compared in daylight when suitable indicators were used. This substitute for the black box comparator was very satisfactory as well as simple to use.

**Concentration of Hydrogen Ion of Hydrolyzed Solutions.**—Using the modified comparator and brom phenol blue indicator, it was found that the hydrolyzed solution giving maximum yields of cystine after addition of sodium acetate showed a concentration of hydrogen ion equal to  $10^{-4}$ .

It was noticed that congo red gives a red color when sodium acetate is added to a hydrolyzed solution in amounts still insufficient to give maximum yields of cystine, and therefore this red color does not indicate that sufficient sodium acetate has been added.

### Hydrolysis of Wool.

A series of hydrolyses of wool was next made to determine the effect of increasing the length of time of hydrolysis on the yield of cystine. Portions of 500 g. of wool were boiled with 1000 cc. of conc. hydrochloric acid for different periods of time and 750 g. of sodium acetate added to aliquots representing 185 g. of wool. Sulfur was determined in the precipitates formed on standing 3 days and also on precipitates in the mother liquor. Alcohol was also added to the mother liquors until they became turbid, and the precipitates thus formed were analyzed.

TABLE II.

HYDROLYSIS WITH CONCENTRATED HYDROCHLORIC ACID. SULFUR AND CYSTINE IN PRECIPITATES FROM ALIQUOTS REPRESENTING 185 G. OF WOOL.

Time of hydrolysis. Hours.	Sulfur. G.	Calc. cystine in wool. %
3	1.618	3.27
4	2.037	4.12
5	2.120	4.29
6	2.135	4.32
12	2.578	5.22
74	0.120	0.24

A study of Table II suggests that 3 hours' hydrolysis is not a sufficient length of time but that there is an increased yield of cystine up to the 12-hour period. The 74-hour period gives practically no yield of cystine. The addition of alcohol gave a slight increase in yield.

<sup>9</sup> Clark and Lubs, *J. Bact.*, 2, 134 (1917).

Hydrolysis was carried out with 6.8 *M* (22%) hydrochloric acid. Two hundred and fifty g. of wool was boiled with 900 cc. of dil. acid for 12 hours. From an aliquot representing 185 g. of wool only 1.532 g. of sulfur was precipitated, but on adding alcohol until the solution became turbid 1.354 g. of sulfur was further precipitated, giving a total calculated yield of cystine equal to 5.84% of the wool. This indicates that hydrolysis with dilute hydrochloric acid gives good yields of cystine, but as the mother liquors obtained from dilute acid contain less hydrolyzed wool per volume they tend to retain more cystine in solution after neutralization. The advantage of using dil. hydrochloric acid is that while pushing the wool into the hot acid no strong hydrogen chloride fumes are evolved to burn the hands.

### Preparation of Pure Cystine.

The quantitative yields of pure cystine obtained from the crude cystine precipitated by sodium acetate as above were determined.

Two portions of 500 g. of wool were boiled with 1000 cc. of conc. hydrochloric acid each, for 6 hours as usual. Sodium acetate sufficient to give a maximum yield of cystine was added. Each washed and dried precipitate was treated as follows. The precipitate was dissolved in 250 cc. of 1.8 *M* (6.5%) hydrochloric acid, filtered by suction, the insoluble portion digested with 2 portions of 50 cc. of hydrochloric acid and filtered. Norite freed from iron and calcium was added equal to 50 g. on the water-free basis, to the combined filtrates, heated and filtered. The Norite was boiled with 2 portions of 100 cc. of 5% hydrochloric acid<sup>10</sup> and filtered. The filtrates were practically colorless. Five hundred cc. of hot sodium acetate trihydrate solution (1:1) was added to the hot combined acid solution. Almost pure cystine was precipitated. Analysis of the white crystals of cystine showed them to be 98.6% pure. By analysis for sulfur before and after use it was found that the Norite had adsorbed 0.313 g. of sulfur. The yield of cystine thus obtained was 4.3% of the wool and practically equal to the yield as calculated from sulfur determined in the crude precipitate.

### Analysis of Pure Cystine.

Pure cystine was obtained by repeatedly dissolving in 1.8 *M* (6.5%) hydrochloric acid and precipitating with sodium acetate solution. Sulfur in one sample was found by 3 determinations by the Carius method to be 26.66%, 26.63% and 26.86% respectively; the calculated sulfur is 26.69%. By the peroxide method with the same sample 26.37% was obtained.

### Cystine Obtained by the Method used by Abderhalden.

Two hundred and fifty g. of wool was boiled under a reflux condenser with 900 cc. of 6.8 *M* (22%) hydrochloric acid for 12 hours, and evaporated to a gummy mass *in vacuo*. This was dissolved in water, made up to 1000 cc., decolorized with Norite, and 100 g. of sodium hydroxide in solution added to the cold filtrate. After standing for 3 days the fine white crystals were filtered with suction. The concentration of hydrogen ion in the filtrate was found to be  $10^{-4.4}$ . The filtrate was evaporated *in vacuo* and a further yield of cystine obtained.

<sup>10</sup> Miss Dennis recommends that bone-black used in decolorizing these precipitates be boiled with dilute acid. *J. Biol. Chem.*, 9, 369 (1911).

TABLE III.  
CYSTINE BY ABDERHALDEN'S METHOD.

	Sulfur. G.	Cystine. G.	Cystine in Wool. %
1st Ppt.	2.910	10.904	4.36
2nd Ppt.	<u>1.429</u>	<u>5.354</u>	<u>2.14</u>
Total	4.339	16.258	6.50

The total yield of cystine obtained by this method was 6.50% of wool. Here again it is noticed that concentration of the mother liquor results in further precipitation of cystine from solution.

The advantage of using sodium hydroxide solution over that of using sodium acetate is that less salt is formed in the mother liquor and concentration of the latter is easier. In Folin's method the mother liquors are saturated with salt.

### The Determination of the Concentrations of Hydrogen Ion in Solutions in which Maximum Yields of Cystine are Obtained.

The hydrogen-ion concentration of the solutions of hydrolyzed wool which on addition of sodium acetate had given the maximum yield was found to be  $10^{-4}$ .

Of special interest are the results obtained in determining the concentration of hydrogen ion in solutions which give maximum and minimum precipitates of cystine from a solution of pure cystine. Three series were run to obtain these results. In each, 10 g. of pure cystine was dissolved in 1.8 *M* hydrochloric acid and made up to 500 cc. with 1.8 *M* hydrochloric acid.

Fifty cc. aliquot portions containing 1 g. of cystine each were run into separate beakers. Sodium acetate trihydrate in solution (1:1) was added from a buret in various amounts to each beaker and distilled water added to make the volume in each case 150 cc. In another series 4.34 *M* sodium hydroxide solution was added first to 50 cc. of the acetate solution and rinsed with water into the aliquots of cystine solution; the volume was then made up as before to 150 cc. After standing for 48 hours at room temperatures the precipitates formed were filtered into weighed Gooch crucibles with asbestos pads, washed thrice with cold water and once each with alcohol and ether. The precipitates were dried at 100°, cooled in the desiccator and weighed.

The concentration of hydrogen ion was determined in the filtrates kept separate from the washings. Standard buffer solutions, the hydrogen-ion concentrations of which had been determined by the electrometric method, were used for comparison in determining the concentration of hydrogen ion in the filtrates by the colorimetric method.

In Table IV are shown the amounts of reagents used, the percentages of cystine obtained and the corresponding concentrations of hydrogen ion.

The maximum yield of cystine was 96.4%. It is clear that addition of the 1 : 1 sodium acetate solution to 1.8 *M* hydrochloric acid gives a maxi-

imum yield when 20 to 30 cc. of the acetate solution is added to 50 cc. of the dil. hydrochloric acid solution of cystine. As the iso-electric point of tyrosine, calculated from the values  $ka=4\times 10^{-9}$  and  $kb=2.6\times 10^{-12}$  as determined by Kanitz<sup>11</sup> and using the formula<sup>12</sup>  $L=\sqrt{\frac{ka}{kb}}\times kw$  is  $10^{-5.4}$ , it is well to precipitate the cystine at a hydrogen-ion concentration greater than that of  $10^{-5.4}$  to obtain it free from tyrosine.

The curve in Fig. 1 follows the values of Table IV. The iso-electric zone for cystine as indicated is a broad one and shows that cystine can be precipitated in solutions of quite varying strengths.

### Summary.

It has been shown that the zone of hydrogen-ion concentration most favorable for the precipitation of cystine from solution is between  $10^{-3}$  and  $10^{-6}$ . To obtain cystine free from tyrosine it is advisable to precipitate it from solution at a concentration of hydrogen ion of about  $10^{-3}$ .

The quantity of sodium acetate required as a buffer in the hydrolyzed solution of wool was determined. When 100 g. of wool is hydrolyzed with 200 cc. of conc. hydrochloric acid, sp. gr. 1.19, 750 g. of sodium acetate trihydrate crystals should be added to 500 cc. of the hydrolyzed solution to insure maximum precipitation of cystine. The concentration of hydrogen ion was determined and found to be  $10^{-4}$ . The highest yield of cystine thus obtained was 5.2% of the weight of the wool taken.

When sodium hydroxide solution was added to a hydrolyzed solution which had been evaporated *in vacuo* and taken up in water, the yield of cystine obtained was 6.5% of the wool. The filtrate contained less salt than that obtained by Folin's method and could therefore be concentrated with less difficulty. Cystine was obtained pure from the crude cystine precipitated by sodium acetate from the hydrolyzed solution of wool and the percentage yield of pure cystine actually obtained agreed with the yield calculated by determination of sulfur in the crude precipitate.

Comparisons were made between the yields of cystine obtained after boiling wool with conc. hydrochloric acid, sp. gr. 1.19, for from 3 to 12 hours with the yield obtained using 6.8 M (22%) hydrochloric acid for hydrolysis. It was found that boiling wool with conc. hydrochloric acid for 12 hours gave the highest yield of cystine. When about 20% hydrochloric acid was used, the solution was so dilute that alcohol had to be added to the buffered mixture. When alcohol was added, the yield of cystine was as high from the dilute acid hydrolysis as with the concentrated. Dil. hydrochloric acid does not evolve the strong acid fumes that the concen-

<sup>11</sup> Kanitz, *Z. physik. Chem.*, **47**, 476 (1906).

Michaelis and Davidsohn, *ibid.*, **30**, 143-50 (1911).

trated acid does and is therefore more convenient to handle although it takes more space.

The amount of cystine adsorbed by the Norite used in decolorizing the crude cystine was found to be small when the Norite had been boiled with dil. hydrochloric acid and filtered after decolorizing.

In determining the hydrogen-ion concentration of dark colored solutions a modification was made in the comparator used by Humitz, Meyer and Ostenberg.

The above investigation was suggested by Dr. H. C. Sherman. Appreciation is due also to Dr. A. W. Thomas and Dr. H. T. Beans for helpful advice.

NEW YORK CITY.

U. S. DEPARTMENT OF AGRICULTURE.]

## THE CHEMICAL COMPOSITION OF CORN OIL.

BY WALTER F. BAUGHMAN AND GEORGE S. JAMIESON.

Received September 1, 1921.

Corn oil is produced from the germ of the corn kernel which is obtained by degerminating corn in the hominy, starch and glucose industries. The germ represents approximately 10% of the dry kernel and contains about 50% of oil. However, the commercially separated germs contain considerable portions from other parts of the corn which reduce the percentage of oil. About 75% of the corn oil output is used after refining for edible purposes. The poorer grades are used for soap making. It has also been used for the preparation of rubber substitutes.<sup>1</sup>

Very little work on the composition of corn oil is reported in the literature. Lewkowitsch<sup>2</sup> states that the unsaturated acids consist of a mixture of oleic and linolic acids and quotes Vulte and Gibson as authority for the statement that the saturated acids consist of palmitic, stearic and arachidic acids. But Hehner and Mitchell<sup>3</sup> could not detect stearic acid. Leathes<sup>4</sup> states that hypogaecic acid occurs in corn oil.

The oil used in this investigation was pressed by means of an oil expeller from corn germs which had been produced by the so-called dry process.

**Physical and Chemical Characteristics.**—The more important physical and chemical characteristics are given in Table I. The saturated and unsaturated acids were determined by the lead-salt ether method.

TABLE I.  
PHYSICAL AND CHEMICAL CHARACTERISTICS.

Specific gravity 25°/25° .....	0.9185
Refractive index 20° .....	1.4717
Iodine number (Hanus) .....	117.2
Saponification value .....	187.3
Unsaponifiable matter% .....	1.7 <sup>a</sup>
Acid value .....	2.5
Acetyl value .....	10.0
Saturated acids (determined)% .....	12.3 <sup>b</sup>
Unsaturated acids and unsaponifiable matter (determined)% .....	83.8
Saturated acids (corrected)% .....	11.2
Unsaturated acids (corrected)% .....	82.5
Iodine number of unsaturated acids and unsaponifiable matter .....	136.9
Iodine number of unsaturated acids .....	137.2
<sup>a</sup> Iodine number .....	113.5
<sup>b</sup> Iodine number .....	12.3

Since a complete separation cannot be effected by this method, the percentages of saturated and unsaturated acids have been corrected for the small amount of unsaturated acids, as indicated by the iodine number of the saturated acid fraction, that contaminate and are weighed with the saturated-acid fraction.<sup>5</sup> The content of unsaponifiable matter represents 1.7% of the oil which is about the average figure for corn oil. When separating the saturated and unsaturated acids by the lead-salt ether method the unsaponifiable matter goes with the unsaturated-acid fraction. Therefore the percentage of unsaturated acids has also been corrected for the unsaponifiable matter content of the unsaturated-acid fraction. The iodine number of the unsaponifiable matter is 113.5 and of the unsaturated-acid fraction containing the unsaponifiable matter, 136.9. The iodine number of the pure unsaturated acids is therefore calculated to be 137.2.

**Unsaturated Acids.**—The bromine addition derivatives of the unsaturated acids (and unsaponifiable matter) were prepared by dissolving a portion of the unsaturated-acid fraction, obtained by the lead-salt ether method, which contained 2% of unsaponifiable matter in absolute ether, cooling the solution to 10° and adding bromine slowly after which the solution was allowed to remain for 2 hours at a temperature of 10–15°. No hexabromide, the bromo derivative of linolenic acid which is insoluble in ether, was found. The excess of bromine was removed from the ethereal solution by washing with an aqueous solution of thiosulfate. After drying with anhydrous sodium sulfate the ether was distilled and the residue dissolved in petroleum ether. This solution was allowed to remain overnight in the ice-box and then linolic tetrabromide which had crystallized was removed by filtration through a Gooch crucible.

<sup>5</sup> THIS JOURNAL, 42, 11, 2398 (1920).

<sup>6</sup> Lewkowitsch, Ref. 2, Vol. 1, p. 573.

The filtrate was reduced in volume, cooled in the ice-box and a second crop of tetrabromide crystals obtained and removed by filtration. The filtrate was evaporated to dryness, weighed, and the bromine content determined. This residue contained the oleic dibromide, the linolic tetrabromide that did not crystallize from the petroleum ether and the bromine derivative of the unsaponifiable matter. The iodine number of the unsaponifiable matter is 113.5 which is equivalent to a bromine number of 71.5. The bromine content of the brominated unsaponifiable matter is, therefore, 41.7%. From these data and the theoretical bromine contents of the linolic tetrabromide (53.33%) and oleic dibromide (36.18%) the percentages of tetrabromide and dibromide in the residue were calculated. The data of the analysis of the bromine derivatives are given below.

	G.	%.
Sample of unsaturated acids containing 2% unsaponifiable matter...	3.1035	....
Linolic tetrabromide insoluble in petroleum ether, m. p. 114°.....	2.0170	....
Residue (dibromide, tetrabromide and brominated unsaponifiable matter).....	3.7669	....
Brominated unsaponifiable matter in residue.....	0.1065	....
Bromine content of residue.....		41.7
Bromine content of mixture of oleic and linolic bromine derivatives .....		41.4
Dibromide in mixture of oleic and linolic bromides.....	2.5462	69.6
Tetrabromide in mixture of oleic and linolic bromides.....	1.1142	30.4
Total tetrabromide.....	3.1312	....
Linolic acid equivalent to tetrabromide.....	1.4612	48.0
Oleic acid equivalent to dibromide .....	1.6245	53.4

The percentage composition of the unsaturated acids, also the amounts of oleic and linolic acids and their glycerides in the oil are given below.

Acid.	Found. %.	Calculated to basis of 100%. %.	Original oil. %.	Glycerides in original oil. %.
Oleic	53.4	52.7	43.4	45.4
Linolic	48.0	47.3	39.1	40.9
Total	101.4	100.0	82.5	86.3

The calculated iodine number of the unsaturated acid mixture having the percentage composition represented in Col. 2 is 133.3, while the determined iodine number of the unsaturated acids after correcting for the unsaponifiable matter is 137.2.

**Test for hypogaeic acid,  $C_{16}H_{30}O_7$ .**—This is an unsaturated acid whose melting point is 33–34°. It was tested for by a method similar to that used for testing peanut oil for hypogaeic acid.<sup>7</sup> A 500g. portion of the unsaturated acid fraction was allowed to remain in a cold storage room where a temperature below 0° was maintained for several days. It had been completely solidified and was removed to another room where the temperature was slightly above 0°. After several days most of the

<sup>7</sup> THIS JOURNAL, 43, 6, 1372 (1921).

mass had liquefied. The small amount of solid material that remained was removed by rapid filtration through a previously cooled Büchner funnel. It weighed about 10 mg. After crystallizing from 75% alcohol it melted at 61–62°. This melting point indicates that it consisted chiefly of palmitic acid with enough impurity (stearic acid) present to lower the melting point. It is believed that corn oil does not contain hypogaeic acid.

*Saturated Acids.*—A portion of saturated acids prepared by the lead salt-ether method was esterified with methyl alcohol.<sup>8</sup> The mixture

of methyl esters was then subjected to fractional distillation under diminished pressure. The data of the distillation are given in Table II. A preliminary distillation was made from a 1-liter Claisen flask, making 5 fractions which are designated by the letters A–E and a residue. The preliminary fractions were redistilled from a 250cc. Ladenburg flask according to the manner indicated in the table. Seven fractions and a residue were obtained.

The iodine numbers which are a measure of the contaminating unsaturated acids and the saponification values of the various fractions are given in Cols. 2 and 3, Table III. Using these data the percentage of unsaturated acids in each fraction was calculated and the saponification values and mean molecular weights corrected accordingly.<sup>9</sup> The mean molecular weights of the saturated acid esters are given in Col. 6.

					0.15 <sup>a</sup>
	56.68	25.47	3.07	1.28	

<sup>a</sup> This amount was crystallized from an alcoholic solution of the free acids from the residue.

Inspection of these results indicates what acids may be present in the various fractions. The mean molecular weights of the saturated acid esters in Fractions 1-5 lie between the molecular weights of methyl palmitate (270.3) and methyl stearate (298.4) and indicate mixtures of these two esters. Fraction 6 is probably a mixture of methyl stearate and methyl arachidate (326.4) while the molecular weight of Fraction 7 is consistent with the presence of behenic acid ester but this acid could not be detected when the free acids from this fraction were fractionally crystallized from alcohol so the probable constituents are methyl arachidate and methyl lignocerate (382.5).

In order to test the correctness of these deductions the free acids were recovered from some of the fractions, subjected to fractional crystallization from alcohol and the constituent acids identified by melting-point determinations and elementary analyses. The following acids were identified.

**Lignoceric Acid,  $C_{24}H_{48}O_2$ .**—By fractionally crystallizing the free acids from Fraction 7 a fraction was obtained which melted at 79-80°.

**Analysis.** Calc. for lignoceric acid: H, 13.13; C, 78.18. Found:<sup>10</sup> H, 13.21; C, 78.26.

<sup>10</sup> Analyses by Chas. E. F. Gersdorff.

The free acid preparation obtained from the highly colored residue was dissolved in alcohol and treated with decolorizing carbon. The acid fraction crystallized from this solution weighed 0.15 g. and had a melting point of about 80°. After 4 recrystallizations the melting point was 80–80.5°. There was not sufficient material for an elementary analysis, but the melting point together with the presence of lignoceric acid in Fraction 7 is sufficient evidence to identify it as lignoceric acid.

**Arachidic acid,  $C_{20}H_{40}O_2$ .**—This acid was separated from the Fraction 7 mother liquor from the lignoceric acid crystallization. On one fraction which melted at 76–77° the following analytical results were obtained.

*Analyses.* Calc. for arachidic acid: H, 12.91; C, 76.85. Found:<sup>10</sup> H, 13.22; C, 76.89. Another fraction which melted at 77° had the following composition:<sup>10</sup> H, 13.07; C, 76.73.

**Stearic Acid,  $C_{18}H_{36}O_2$ .**—From Fraction 5 an acid was obtained which melted at 68–69°.

*Analysis.* Calc. for stearic acid: H, 12.76; C, 75.98. Found:<sup>10</sup> H, 12.82; C, 76.05.

**Palmitic acid,  $C_{16}H_{32}O_2$ .**—This acid was isolated from Fraction 1. It melted at 62.5°.

*Analysis.* Calc. for palmitic acid: H, 12.59; C, 74.92. Found:<sup>10</sup> H, 12.30; C, 74.73.

The qualitative composition of the saturated acids having been established the quantitative composition is calculated from the mean molecular weight of the saturated acid esters as determined (Col. 6, Table III) and the theoretical molecular weights of the two esters in each fraction. Thus the percentages and amounts of acids present in each fraction were calculated.

TABLE IV.  
SATURATED ACIDS.

	G.	Percentage composition. %.	Original. %.	Glycerides in original oil. %.
Palmitic	56.68	65.6	7.3	7.7
Stearic	25.47	29.4	3.3	3.5
Arachidic	3.07	3.5	4	.4
Lignoceric	1.28	1.5	.2	.2
	86.50	100.0	11.2	11.8

Table IV gives in Col. 2 the percentage composition of the saturated acids, in Col. 3 the percentage of acids in the original oil, and in Col. 4 the equivalent percentages of glycerides.

### Summary.

The chemical composition of corn oil has been determined with the following results.

COMPOSITION OF CORN OIL.	
Glycerides of.	%.
Oleic acid .....	45.4
Linolic acid .....	40.9
Palmitic acid .....	7.7

COMPOSITION OF CORN OIL (*continued*).

Glycerides of.	%.
Stearic acid .....	3.5
Arachidic acid .....	0.4
Lignoceric acid .....	0.2
Unsaponifiable matter .....	1.7

WASHINGTON, D. C.

## NEW BOOKS.

**Pyrometric Practice.** Technologic Paper of the Bureau of Standards, No. 170. By PAUL D. FOOTE, C. O. FAIRCCHILD, and T. R. HARRISON. Government Printing Office, Washington, D. C., 1921. 326 pp. 185 figs. 18 × 25.5 cm. Price \$0.60; from Supt. of Documents.

Only a few years ago the average investigator knew little of pyrometry. The whole subject was a vast mystery to him; he knew something of the use of a mercury thermometer, but a thermocouple, a resistance thermometer, or a radiation-pyrometer would not have been recognized by him, much less understood. To-day the chemist, as well as the physicist and the engineer, is obliged to make frequent and increasing use of one or more of the modern types of thermometer. In the laboratory some form of pyrometer is an indispensable tool; in the plant the size and importance of pyrometric installations has created a new profession, "pyrometric engineering."

This publication is a clear and thorough presentation of the technic of temperature measurement. The authors possess a first-hand knowledge of the subject, and have made frequent contributions to the various branches of pyrometry. The scope of the book is shown by the following list of chapter-headings: Temperature Scale; High-temperature Thermometry; Thermoelectric Pyrometry; General Theory of Optical and Radiation Pyrometry; Optical Pyrometry; Radiation Pyrometry; Resistance Thermometry; Recording Pyrometry; High Temperature Control; Melting-point Methods at High Temperatures; Standardization of Pyrometers; and Industrial Applications of Pyrometry.

As indicated by the title, the book is primarily concerned with the practical side of the subject. It contains "nothing of the historical, and the purely scientific aspects of pyrometry have been intentionally subordinated. It purports to describe practical methods in use in the industries in the year 1920." Nevertheless the theoretical foundations of the various phases of temperature-measurement are recorded, insofar as they are required for a proper understanding of the instruments and methods. While this treatise naturally will find its widest use in connection with industrial installations, it will be helpful to anyone who is called upon to measure temperatures. Of especial value to the research worker is the

chapter on "Melting-point Methods at High Temperatures." The general usefulness of the book would have been enhanced by a description of the deviation-curve and standard-table method of using a thermocouple. The Appendix contains standard tables for the copper-constantan and for the platinum-platinrhodium couples, but no hint is given as to what the tables are used for.

The publication is unusually free from typographical errors. The reviewer noted none, except on p. 170 "enunciator" for "annunciator."

The references are comparatively few; no attempt was made to include a complete bibliography of the subject.

LEASON H. ADAMS.

**Organic Syntheses.** An Annual Publication of Satisfactory Methods for the Preparation of Organic Chemicals. Vol. 1. Editorial Board: ROGER ADAMS, Editor-in-Chief, University of Illinois, Urbana, Illinois; HANS THACHER CLARKE, Eastman Kodak Company, Rochester, N. Y.; JAMES BRYANT CONANT, Harvard University, Cambridge, Massachusetts; OLIVER KAMM, Parke, Davis and Company, Detroit, Michigan. John Wiley and Sons, Inc., New York; Chapman and Hall, Limited, London, 1921. vii + 84 pp. 7 fig. 23.5 × 15 cm. Cloth. Price, \$1.50.

This is the first number of a series of pamphlets which the editors propose to issue annually. It is an outcome of the admirable work that was inaugurated by the senior editor when the war cut us off from our largest supply of pure organic chemicals. The main purpose of the series is to supply the investigator with reliable directions for making, in 200g. to 2.5kg. lots, the substances he most frequently needs for his work. In return the authors make the reasonable request that investigators who have had occasion to prepare other organic compounds on a reasonably large scale, report their results for verification and publication in the pamphlets. The authors "hope to make this (series) a clearing house for the exchange of information as to methods of preparation of some of the most needed organic chemicals."

Very few of the methods presented are new, most of them being based on the most satisfactory methods published. Some one of the authors has selected the most promising method, studied it carefully, and prepared a set of directions to be verified or improved by one of the other authors. Only such directions as gave results which were exactly duplicated in both laboratories were deemed ready for publication. The directions are excellent in their definiteness. They specify the best type and size of apparatus to be used, the most favorable temperature, the time required for each step in the process, the precautions that must be taken, the yield of substance sufficiently pure for most purposes, and the best method for getting the purest product. Each preparation is accompanied by explanatory notes and a bibliography which gives references to all of the methods by which the substance has been obtained.

The apparatus specified is in most cases such as is found in any labor-

atory, but the pamphlet also contains descriptions and drawings of some new and ingenious devices that will be found equally useful in other work. The emphasis laid on adequate mechanical agitation is altogether commendable, as is also the substitution of cheap for expensive solvents wherever possible.

The first number describes 23 preparations, selected at random, because the directions for making them happened to be ready for publication. It is expected that each subsequent issue will contain at least 20, and the authors hope that as interest in the work is stimulated this number may be considerably increased. Anyone who has had experience in the preparation of organic compounds on a moderately large scale will appreciate the care and intelligence with which the authors have considered everything that might affect the results.

The pamphlet deserves a wide distribution. For the investigator it is invaluable. The chemical manufacturer will find that most of the methods can be readily developed for production on a larger scale. The instructor in organic chemistry, by cutting down the quantities, will be able to supply his students with directions better than any heretofore available, prepare more interesting as well as more useful substances, and by assigning different preparations in successive years, stock his treasure chest without depleting his purse.

The review hazards the prediction that the new venture will receive such hearty support that the editors will be encouraged to continue the good work. It seems to him that many teachers, whose time and energies are so largely taken up by instruction that protracted systematic research is out of the question, would find it a welcome and profitable diversion to undertake the intensive study of some one preparation and thus contribute to the success of the series.

# Subject Index to Volume XLIII, 1921.

<b>ABSORPTION</b> of CO by cuprous ammonium carbonate solns. ....	1
Acetaldehyde, influence of KOH on the formation of vinyl alc. from, 1925; Hg salts in the catalytic transformation of acetylene into, 2071; lab. prepn. of. ....	2420
<i>p</i> -Acetoxyacetanilide, distribution between immiscible solvents. ....	2323
Acetylene, condensation with benzene and its derivs. in the presence of $AlCl_3$ , 334; some phys. properties of, 1098; in glassblowing, 1319; Hg salts in the catalytic transformation of, into $CH_3CHO$ . ....	2071
Acid halides, reaction between aldehydes and. ....	651, 660
Acids, influence of Cu on the rate of soln. of Fe in, 452; identification of, sepn. by means of phenacyl esters, 629; compd. formation and sp. cond. in solns. of the types, acid : ester, acid : ketone and acid : acid, 1426; solubilities of, in aq. solns. of other, 1545; compd. formation and viscosity in solns. of the types, ester : acid, ketone : acid and acid : acid. ....	1826
Adhesion. ....	35
Adipose tissue, enzymes of the abdominal, of the turkey. ....	1963
Adsorption, of gases by metallic catalysts, 1273; of Ra by $BaSO_4$ , 1615; high pressure due to, 1787; of gases by solid bodies. ....	2127
Air, detg. the density of, 1317; Joule-Thomson effect for. ....	1452
Alcohols, purification and some phys. properties of certain aliphatic. ....	561
Aldehyde acids, Anleitung zum Nachweis, zur Trennung und Bestimmung der reinen und aus Glukosiden usw. erhaltenen Monosaccharide und (van der Haar, book rev.) ....	685
Aldehydes, reaction between acid halides and, 651, 660; action of $PCl_5$ on satd. ....	1928
Alfalfa, distribution of N in the, seed, 906; N compds. in, hay. ....	2656
Alkali metal bromates, rarer. ....	2031
Alkali metal halides, reaction with Hg derivs. of phenol. ....	619
Alkali metals, conductance of the, in liquid $NH_3$ . ....	749
Alkaloids, Some Microchem. Tests for—Chem. Tests of the Alkaloids Used (Stephenson, Parker, book rev.) ....	2480
Alkoxyl groups, prepn. of esters by direct replacement of. ....	945
Allotropy, theory of. ....	1870
Allylene, some phys. properties of. ....	1098
Aluminum chloride, condensation of $C_6H_2$ with benzene and its derivs. in the presence of, 334; Friedel and Crafts' reaction—carbomethoxy-benzoyl chlorides with aromatic hydrocarbons and, 1920; Friedel and Crafts' reaction—bromophthalic anhydrides, benzene and, 1950; Friedel and Crafts' reaction—some substituted phthalic anhydrides with toluene and. ....	2577
Aluminum phosphates, origin of. ....	381
Amalgams, thermodynamic treatment of concd. solns., and applications to Tl, 233; structure of Au. ....	740
Amines, addition of aromatic, to bromonitrostyrene, 919; mercurization of aromatic, 1894; Die Biogenen, und ihre Bedeutung für die Physiologie und Pathologie des Pflanzlichen und Tierischen Stoffwechsels (Guggenheim, book rev.) ....	2129
Amino acids, influence of certain, on the enzymic hydrolysis of starch. ....	2461
Aminobenzoic acids, esters of, 1320; <i>o</i> -diethylamino-cyclohexanol ester of <i>p</i> . ....	1370
2-Amino- <i>p</i> -cymene, bromination of. ....	2611
3-Amino-4-hydroxyphenylarsonic acid, indirect reduction to arsphenamine. ....	370
Aminotriphenylamines. ....	2630
Ammino compounds, heats of soln. and of transformation of the acido and aquo Co pentammines, 2188; soly. in salt solns., 2265; strengths of cobaltamine bases and Werner's theory of bases. ....	2352
Ammonia, conductance of the alkali metals in liquid, 749; equil. in the system: $NH_4NO_3$ : $NH_4CNS$ —1018; equil. in the system $H_2O$ : $NH_4CNS$ —, 1031; production of dry, 1178; vapor pressure of $LiNO_3$ system, 1575; vapor pressure of, -salt solns., 1580; ionization of aq. solns of, in the presence of urea, 1632; (Maxted, book rev.), 1747; Mn in the catalytic oxidation of, 2034; action of, water on dicyanodiamide, 2230; conductance of concd. solns. of Na and K in liquid, 2529; nesslerization of, solns. ....	2574
Ammonium chloroplatinate, crystal structure of. ....	2292
Ammonium copper carbonate, absorption of CO by. ....	1
Ammonium halides, crystal structures of the. ....	84
Ammonium nitrate, equil. in the system, $NH_3$ : $NH_4CNS$ —, ....	1018
Ammonium phosphomolybdate, co-pptn. of vanadic acid with. ....	2552
Ammonium thiocyanate, equil. in the system, $NH_3$ : $NH_4NO_3$ —, 1018; equil. in the system $NH_3$ : $H_2O$ —, ....	1031

Amylases, effect of certain antiseptics on the activity of, 2454; influence of arginine, histidine, tryptophan and cystine on the hydrolysis of starch by purified pancreatic.....	2469
Analysis, identification of acids—sepn. of acids by means of phenacyl esters, 629; A course of Instruction in the Qual. Chem., of Inorg. Substances (Noyes, book rev.), 1209; Qual., of Medicinal Preps. (Fuller, book rev.), 1212; of Drugs and Medicines (Fuller, book rev.), 1213; Die störenden Einflüsse auf das Eintreten und die Eindeutigkeit analytischer Reaktionen (Stadlin, book rev.), 1747; Analytische Chemie (Döring, book rev.), 2127; Die Elektrometrische Massanalyse (Müller, book rev.).....	2703
Aniline, action of $\text{AsCl}_3$ on.....	2449
Anthracene, synthesis from $\text{C}_{10}\text{H}_8$ .....	898
Anthranilic acid, detection of methyl ester of, in fruit juices, 377; occurrence of Me ester of, in grape juice.....	1741
Antraquinone, derivs. of.....	2104
Antimony, revision of the at. wt. of.....	797
Antimony bromide, analysis of.....	797
Antimony trisulfide, polymorphic transformations of.....	2178
Antipyrine, distribution between immiscible solvents.....	2323
Antiseptic properties, prepn. of some alkyl derivs. of resorcinol and the relation of their structure to.....	348
Antiseptics, effect of certain, on the activity of amylases.....	2454
Apparatus, repair of crystd. glass, 11, 1319; Bur. of Chemistry aids research chemists.....	966
Apples, odorous constituents of.....	1741
Argentichloride ions, existence of complex.....	2492
Arginine, influence on the hydrolysis of starch by purified pancreatic amylase.....	2469
Aristol.....	553
Arsanilic acid, diazo-amino compds. of, and its derivs., 1632; azo dyes derived from.....	1646
Arsenate, sepn. and detection of, and arsenite.....	466
Arsenic, estn. in org. compds., 182; sepn. of Ge and.....	2549
Arsenic compounds, related to arspenamine, 582; aromatic, 1632, 1646; arsenated benzophenone and its derivs., 2117; relation between the mode of synthesis and toxicity of arspenamine and related compds.....	2202
Arsenious chloride, action on aniline.....	2449
Arsenite, sepn. and detection of arsenate and.....	466
Arsphenamine, indirect reduction of 3-amino-4-hydroxyphenylarsonic acid to, 370; relation between the mode of synthesis and toxicity of.....	2202
Asphalt, in the tar sands of Northern Alberta.....	1337
Atomic nucleus, at. wts. of pure at. species as related to nuclear stability.....	1038
Atomic weights, 27th annual rept. of Committee on, 383; of pure at. species as related to nuclear stability, 1038; rept. of the Intern. Comm. on, for 1921-22.....	1751
Atoms, magnitude of, 1584; Langmuir's theory of the arrangement of electrons in.....	1602
Azotropism, (Lecat, book rev.).....	1745
<b>BARIUM</b> , isotopism of mesothorium and Ra and sepn. of these elements from.....	440
Barium peroxide, catalytic influence of foreign oxides on the decompn. of.....	2017
Barium sulfate, adsorption of Ra by.....	1615
Bases, strengths of cobaltamine bases and Werner's theory of.....	2352
Bean, carbohydrate content of the navy.....	1180
Benzal acetophenone, equil. between $\text{PCl}_5$ and, 1712; addition of $\text{PBr}_3$ to.....	1713
Benzene, viscosity of liquids (V) ideality of the system: benzyl benzoate-, 115; distribution of a strong electrolyte between water and, 254; condensation of $\text{C}_6\text{H}_6$ with, and its derivs. in the presence of $\text{AlCl}_3$ , 334; reactivity and conductance of, solus., 646; surface tension data for, 827; compressibility of liquid and solid, 1538; effect of finely divided material on the f. p. of, 1011; Friedel and Crafts' reaction—bromophthalic anhydrides, $\text{AlCl}_3$ and.....	1950
Benzoic acid, rearrangement.....	935
Benzoic acid, viscosity of liquids (V) ideality of the system, benzene: benzyl ester of.....	115
Benzophenone, arsenated, and its derivs.....	2117
Benzyl esters, new, possessing an antispasmodic action, 361; prepn. and hydrolysis of.....	1672
Benzyl ethers, of carbohydrates.....	1904
Bingham fluidity formula, validity of.....	115
Biochemistry, Practical (Bertrand, Thomas, book rev.).....	1968
Biographies, Eminent Chemists of our Time (Harrow, book rev.), 959; James Cutbush (Smith, book rev.), 1743; Priestley in America, 1794-1804 (Smith, book rev.), 1967; John Harper Long (Gault, book rev.).....	2125
Bismuth, surface tension and density of liquid.....	1621
Bismuth subsalts.....	2367

Boiling points, Cottrell's ebullioscopic app., 301; app., 566; application of a differential thermometer in ebullioscopy.....	2314
Books, new (Reviews): Radioaktivitaet (Meyer, v. Schweidler), 213; History of Chemistry from the Earliest Times (Brown), 215; Practical Chemistry, Fundamental Facts and Applications to Modern Life (Black, Conant), 216; Festschrift aus anlass des siebenzigsten Geburtstages von Cornelio Doelter (Leitmeier), 381; Anleitung zum Nachweis, zur Trennung und Bestimmung der reinen und aus Glukosiden usw. erhaltenen Monosaccharide und Aldehydsäuren (van der Haar), 685; Text-book of Physical Chemistry (Lincoln), 687; Chemistry and Civilization (Cushman), 688; Chem. Reactions. Their Theory and Mechanism (Falk), 690; Eminent Chemists of Our Time (Harrow), 959; Zur Feier der Entdeckung der Röntgenstrahlen vor fünfundzwanzig Jahren, 959; Die Reaktionen des freien Stickstoffs (Moldenhauer), 963; Introduction to General Chemistry (Copaux), 964; Lab. Expts. in Org. Chemistry, 964; Vocational Chemistry, for Students of Agriculture and Home Economics (Willaman), 965; Applied Colloid Chemistry, General Theory (Bancroft), 1207; A Course of Instruction in the Qual. Chem. Analysis of Inorg. Substances (Noyes), 1209; Scientific and Applied Pharmacognosy (Kraemer), 1210; Qual. Analysis of Medicinal Preps. (Fuller), 1212; Chemistry and Analysis of Drugs and Medicines (Fuller), 1213; Chemistry of Plant Life (Thatcher), 1214; Bibliography of Investigations Bearing on the Compn. and Nutritive Value of Corn and Corn Products (Keith), 1215; Geschichte der Organischen Chemie (Graebe), 1382; Notes on Chem. Research (Dreaper), 1383; James Cutbush: An American Chemist, 1788-1823 (Smith), 1743; La Tension de Vapeur des Mélanges de Liquides: L'Azétotropisme (Lecat), 1745; Ammonia and the Nitrides (Maxted), 1747; Die störenden Einflüsse auf das Eintreten und die Eindeutigkeit analytischer Reaktionen (Stadlin), 1747; Chemistry and Technology of the Diazo Compds. (Cain), 1748; Org. Chem. Reagents (II) (Adams, Kamm, Marvel), 1748; Vitamines: Essential Food Factors (Harrow), 1749; Chem. Effects of $\alpha$ Particles and Electrons (Lind), 1966; Priestley in America, 1794-1804 (Smith), 1967; Practical Biol. Chemistry (Bertrand, Thomas), 1968; Chemistry of Synthetic Drugs (May), 1970; Org. Medicinal Chemicals (Synthetic and Natural) (Barrowcliff, Carr), 1970; Chemistry Review Book (Kessel), 1971; John Harper Long (Gault), 2125; Grundriss der Kolloidchemie (Ostwald), 2126; Analytische Chemie (Döring), 2127; Festschrift der Kaiser Wilhelm Gesellschaft zur Förderung der Wissenschaften, 2127; French-English Dictionary for Chemists (Patterson), 2128; Die Biogenen Amine und ihre Bedeutung für die Physiologie und Pathologie des Pflanzlichen und Tierischen Stoffwechsels (Guggenheim), 2129; Die Welt der vernachlässigten Dimensionen (Ostwald), 2261; Oedema and Nephritis (Fischer), 2262; Lehrbuch der Cellulosechemie (Heuser), 2263; Tables of Phys. and Chem. Consts. and some Mathematical Functions (Kaye, Laby), 2258; Principles of the Phase Theory (Clibbens), 2259; Allgemeine Photochemie (Plotnikow), 2280; Physical Chemistry for Colleges (Millard), 2477; Physikalisch-chemische Übungen (Roth), 2477; Some Microchem. Tests for Alkaloids (Stephenson), Chem. Tests of the Alkaloids Used (Parker), 2480; Die Schwimmaufbereitung der Erze (Vageler), 2482; Physiology of Protein Metabolism (Cathcart), 2482; Organic Syntheses (Adams, Clarke, Conant, Kamm), 2702; Die Elektrometrische Massanalyse (Müller).....	2703
Bromate ion, electrometric detn. of.....	1309
Bromonitrostyrene, addition of aromatic amines to.....	919
Bromophthalic anhydrides, Friedel and Crafts' reaction—benzene, $AlCl_3$ and.....	1950
Bromoquinaldines.....	2257
Buffers, phthalate,—some incompatibilities.....	914
Bur. of Chemistry aids research Chemists.....	966
Butyl alcohol, purification and some phys. properties of, 561; sepn. of, and water.....	368
sec.-Butyl alcohol, purification and some phys. properties of.....	561
dl-p-sec.-Butylaniline, resolution of.....	2682
Butyl-cyano-acetic acid.....	672
Butyl ether, prepn. of.....	368
Butyl mercaptan, some derivs. of, and their $HgI$ compds.....	638
Butyl mercapto-ethyl alcohol.....	636
Butyl oxalate, prepn. of.....	369
dl-p-sec.-Butylphenylhydrazine, prepn. of.....	2682
<b>CADMIUM</b> , revision of the at. wt. of — detn. in $CdSO_4$ , 1230; surface tension and density of liquid.....	1621
Cadmium chloride, thermochem. data of.....	484
Cadmium iodide, thermochem. data of.....	484
Cadmium sulfate, detn. of $Cd$ in.....	1230
Caffeine, distribution between immiscible solvents.....	2323
Calcium, ionization of, vapor in the sun's atm.....	1631
Calorimeter, modifications of the adiabatic.....	875

- Carbohydrates, in the navy bean, 1180; benzyl ethers of..... 1904
- Carbomethoxybenzoyl chloride, Friedel and Crafts' reaction—with aromatic hydrocarbons and  $AlCl_3$ ..... 1920
- Carbon, allotropy of, 1879; catalysis in the interaction of, with steam and with  $CO_2$ , 2055; existence and reactions of positive halogen attached to, in aromatic compds., 2081; method of linking C to C..... 2238
- Carbon dioxide, catalysis in the interaction of C with..... 2055
- Carbon monoxide, absorption by cuprous ammonium carbonate solns., 1; oxidation by passage with O or air through the silent discharge and over  $O_2$  decomp. catalysts, 967; catalytic oxidation of..... 1973, 1982
- Carbon tetrachloride, surface tension data for..... 827
- Carbonyl group, addition reactions of the, involving the increase in valence of a single atom, 1705, (correction)..... 2125
- Castor bean lipase..... 2664
- Catalysis, in decompn. of certain phenol Ag salts, 131, 135, 151; periodic reaction in homogeneous soln. and its relation to, 1282; oxidation of CO, 1973, 1982; influence of foreign oxides on the decompn. of  $Ag_2O$ ,  $HgO$  and  $BaO_2$ , 2017; Mn in the catalytic oxidation of  $NH_3$ , 2034; in the interaction of C with steam and with  $CO_2$ , 2055; Hg salts in, of acetylene into  $CH_3CHO$ .... 2071
- Catalysts, oxidation of CO by passage with O or air over  $O_2$ -decomp. catalysts, 967; adsorption of gases by metallic..... 1273
- Cathode, use of the Ag, in electro-deposition of Cu..... 700
- Cells, voltaic, satd. KCl calomel cell (correction)..... 302
- Cellulose. *Lehrbuch der Cellulosechemie* (Heuser, book rev.)..... 2263
- Cesium chloride, heat of diln. and the sp. heat of dil. solns. of..... 770
- Cesium hydroxide, heat of diln. and the sp. heat of dil. solns. of..... 770
- Cesium nitrate, heat of diln. and the sp. heat of dil. solns. of..... 770
- Charcoal, density and vol. relations of..... 1787
- Chemical compounds, formation and soly. in systems of the type  $H_2SO_4$  and metal sulfate, 979; unsatn. and mol. compound formation, 1227; factors affecting the stability of addition compds. in soln. and their influence upon ionization equilibria, 143; formation in sp. cond. in solns. of the types acid:ester, acid:ketone and acid:acid, 142; formation in soly. in systems of the type, formic acid:metal formate, 1470; formation of addition compds. in solns. of the types acid:ester, acid:ketone, and acid:acid, 1826; formate and formic acid systems of the types formic acid:metal formate and  $H_2SO_4$ :metal sulfate, 1846; formation in phenol:cresol mixts..... 1853
- Chemical constants, Tables of (Kaye, Laby, book rev.)..... 2258
- Chemical constitution, prepn. of some alkyl derivs. of resorcinol and the relation of their, to antiseptic properties..... 348
- Chemicals, Bur. of Chemistry aids research chemists..... 966
- Chemistry, History of, from the Earliest Times (Brown, book rev.), 215; Practical, Fundamental Facts and Applications to Modern Life (Black, Conant, book rev.), 216; and Civilization (Cushman, book rev.), 688; Introduction to General (Copaux, book rev.), 964; Vocational, for Students of Agriculture and Home Economics (Willaman, book rev.), 965; statistical mechanics and, 1251; Review Book (Kessel, book rev.), 1971; French-English Dictionary for Chemists (Patterson, book rev.)..... 2128
- Chemists, Eminent, of Our Time (Harrow, book rev.)..... 959
- Chloral, ethers derived from the addition products of the nitro-anilines and..... 941
- Chloride, potentials at the junctions of monovalent solns. of..... 2563
- Chloride ion, electrometric detn. of..... 1300
- Chlorination, by means of  $NCl_3$ ..... 2211
- Chlorine, conduct of mixts. of N and, in a flaming arc, 1774; sepn. into isotopes..... 1803
- Chloro-amines, formation by means of  $NCl_3$ ..... 2211
- Chlorobenzene, reaction with  $HNO_3$  contg. Hg..... 600
- 7-Chloro-7,12-dihydro- $\gamma$ -benzophenarsazin and derivs..... 2218
- Chloroform, surface tension data for..... 827
- Chlorohydrocarbons, elimination of HCl from..... 1715
- Chloroplatinic acid, prepn. of..... 2575
- Chromium, qual. sepn. and detection of U, V, and, when present together..... 114
- Chromo-isomerism, theory of, of solid compds..... 1654
- Cinnamylidene-acetophenone, addition reactions of P halides with..... 1677
- Civilization, Chemistry and (Cushman, book rev.)..... 688
- Coal, Origin and Structure of..... 2127
- Cobalt, detection and estn. of, 482; reagent for the detection of..... 746
- Cobaltamines, heats of soln. and of transformation of the anhydrous and aquo Co pentamines 2188; strengths of, and Werner's theory of bases..... 2352
- Cohesion..... 35

Colloidal chemistry, Applied (Bancroft, book rev.), 1207; Grundriss der (Ostwald, book rev.)...	2126
Colloidalilty, zone of max.....	434
Colloids, zone of max. colloidalilty—its relation to viscosity in hydrophile, especially karaya gum and gelatin, 434; photometric methods and app. for the study of, 531; action of ultra-violet light on colloidal Pt, 1385; viscosity of gelatin sols, 1764; organogels of silicic acid, 1844; protective and coagulating action of hydrophilic, on hydrophobic sols, 2127; heat of wetting of Si gel, 2144; an interesting gel, 2199; Die Welt der vernachlässigten Dimensionen (Ostwald, book rev.), 2261; heat of coagulation of $\text{Fe}_2\text{O}_3$ hydrosol with electrolytes.....	2336
Colorimeter.....	532
Columbium, sepn. of Ta and.....	2378
Compressibility, of benzene.....	1538
Conductance, electric, reactivity and, of $\text{C}_2\text{H}_5$ sols., 646; of the alkali metals in liquid $\text{NH}_3$ , 749; new method of measuring, 1095; ion, and the effect of viscosity on the, of certain salts, 1217; compd. formation and sp., in sols. of the types acid: ester, acid: ketone and acid: acid, 1426; of sols. of ternary electrolytes in propyl alc., 1568; compd. formation and, in systems of the types formic acid: metal formate and $\text{H}_2\text{SO}_4$ : metal sulfate, 1846; of concd. sols. of Na and K in liquid $\text{NH}_3$ .....	2529
Copper, influence on the rate of soln. of Fe in acids, 452; reaction between $\text{NO}_2$ and, 494; use of the Ag cathode in electro-deposition of, 700; system: $\text{CuO}-\text{O}$ .....	1061
Copper, ammonium carbonate, absorption of CO by cuprous.....	1
Copper oxide, system, $\text{Cu}-\text{Cu}-\text{OO}$ , 1061; reduction of $\text{CuO}$ by H.....	2179
Corn, Bibliography of Investigations Bearing on the Compn. and Nutritive Value of, and, Products (Keith, book rev.).....	1215
Corn oil, chem. compn. of.....	2696
Cresol, compd. formation in mixts. with phenol.....	1853
Crystal structure, of the $\text{NH}_4$ halides above and below the transition temps., 84; detn. by roentgenography, 381; of $\text{NaClO}_3$ and $\text{NaBrO}_3$ , 2045; of $(\text{NH}_4)_2\text{PtCl}_6$ .....	2292
Cutbush, James, (Smith, book rev.).....	1743
Cyano-acetic acid, alkyl esters of.....	205
Cyclobutane-1,5- <i>spiro</i> -pyrimidines.....	677
Cyclohexane-1,5- <i>spiro</i> -pyrimidines.....	1366
Cyclopropane-1,1-dicarboxylic acid, condensation of Et ester of, with ureas.....	2097
<i>p</i> -Cymene, studies.....	2611
Cystine, influence on the hydrolysis of starch by purified pancreatic amylase, 2469; exptl. studies on.....	2688
<b>DENSITY</b> , detn. of, of certain liquid hydrocarbons, 1103; detg. the, of air, 1317; of liquid Hg, Cd, Zn, Pb, Sn and Bi.....	1621
Devitrification, of glass.....	11
Dialysis, influence of glucose on the, of sucrose through a parchment membrane. Sepn. of glucose from sucrose by.....	2588
Diazo compounds, Chemistry and Technology of the (Cain, book rev.).....	1748
Dibenzalacetone, addition reactions of P halides with.....	1677
Dichloro chromic chlorides, hydrolysis of.....	1154
$\beta, \beta'$ -Dichlorodiethyl ether.....	2223
$\beta, \beta'$ -Dichloroethyl sulfide, intersoly. of, and ethyl alc.....	877
Dichromate ion, electrometric detn. of.....	1309
Dictionary, French-English. for Chemists (Patterson, book rev.).....	2128
Dicyanodiamide, action of $\text{H}_2\text{SO}_4$ on, 669; action of ammonia water on.....	2230
Dielectric constants, measurement of.....	1835
<i>o</i> -Diethylaminocyclohexanol, ester of <i>p</i> -aminobenzoic acid.....	1370
$\gamma, \gamma'$ -Dihalogenobipropyl ethers.....	2228
$\alpha$ -1,3-Dihydroxybutyric acid, prepn. and resolution of. Some derivs. of the optically active acids.....	2675
Dihydroxytartaric acid.....	2091
Diisopropylhydrazine, symmetrical, and its derivs.....	2597
Dilution, free energy of, and the activities of the ions of KBr in aq. sols.....	2483
Dimethylaniline, surface tension data for.....	827
2,4-Dimethylpyridine.....	1939
2,6-Dimethylpyridine.....	1939
2,4-Dinitrobenzaldehyde, derivs. of.....	346
Diphenyl, new reactions of, and its derivs.....	896
Diphenylacetic acid, rearrangements of some new hydroxamic acids related to.....	2422
Diphenylamine reaction.....	685
Diphenylketene, non-addition of $\text{H}_2\text{O}_2$ to.....	935
<i>p</i> -Diphenylpropionic acid, prepn. of.....	896
Dispersimeter.....	534

Dissociation pressures of Fe nitrides.....	475
Dissolution, influence of Cu on the rate of soln. of Fe in acids.....	452
Dithio-ethers, derivs. of anthraquinone.....	2104
Doelter, Cornelio, Festschrift aus anlass des siebenzigsten Geburtstages von (Leitmeier, book rev.).....	381
Drugs. See <i>Pharmaceutical preparations.</i>	
Dyes, azo, derived from arsanilic acid.....	1646
<b>ECONOMICS</b> , science and.....	2127
Edema, and nephritis (Fischer, book rev.).....	2262
Elaidic acid, relation to its halogen addition products.....	2122
Elasticity, elastic properties of gelatin jellies.....	539
Electric arc, conduct of mixts. of N and Cl in a flaming.....	1774
Electric discharge, oxidation of CO by passage with O or air through the silent.....	967
Electric resistor, variable.....	1179
Electrode, Zn, observations on.....	81
Electrolytes, distribution of a strong, between benzene and water, 254; activity coeff. of strong, 1112; conductance of solns. of ternary, in propyl alc., 1568; heat of coagulation of Fe <sub>2</sub> O <sub>3</sub> hydrosol with, 2336; equil. in mixts. of binary, 2507; Ghosh's theory of electrolytic solns.....	2514
Electron gas, entropy of.....	1592
Electrons, Langmuir's theory of the arrangement of, in atoms and mols., 1602; Chem. Effects of (Lind, book rev.).....	1966
Eleostearic acid tetrabromide, non-identity of, from tung oil, with ordinary linolic acid tetrabromide.....	938
Energy, free, of diln. and the activities of the ions of KBr in aq. solns.....	2483
Entropy, mass effect in the, of solids and gases, 818; of polyatomic gases, 866; of electron gas.....	1592
Enzymes, of the abdominal adipose tissue of the turkey, 1963, influence of certain amino acids on the enzymic hydrolysis of starch.....	2461
Equilibrium, conditions of the reaction between manganate, permanganate and MnO <sub>2</sub> , 294; calcul. of rates of reactions and, const., 397; between NO, NO <sub>2</sub> and aq. soln. of HNO <sub>3</sub> , 518; in the system: NH <sub>3</sub> :NH <sub>4</sub> NO <sub>2</sub> :NH <sub>4</sub> CNS, 1018; in the system, NH <sub>3</sub> :H <sub>2</sub> O:NH <sub>4</sub> CNS, 1031; factors affecting the stability of addition compds. in soln. and their influence upon ionization, 1416; biological, in infections, 2127; in mixts. of binary electrolytes.....	2507
Erbium earths, concn. of the.....	1397
Esterification, automatic separator in, 386; application of Victor Meyer's, law to 2,8-xylic acid and its reduced derivs.....	925
Esters, prepn. of, by direct replacement of alkoxyl groups, 945; compd. formation and sp. cond. in solns. of the type acid: ester 1426; compd. formation and viscosity in solns. of the type acid: ester.....	1826
Ethane, some phys. properties of.....	1098
Ethers, derived from the addition products of the nitro-anilines and chloral.....	941
Ethyl alcohol, purification and some phys. properties of, 561; intersoly. of $\beta$ , $\beta$ -dichloro-ethyl sulfide and.....	877
Ethylene, some phys. properties of.....	1098
Ethyl ether, surface tension data for.....	827
Ethyl oxalate, prepn. of.....	368
<b>FATTY</b> acids, C <sub>18</sub> , 938, 2122; quant. sepn. of the Pb salts of the satd. from the less unsatd. ....	1323
Feeding stuffs, application of the Van Slyke method to hydrolyzed protein exts. of silage crops..	951
Flotation, Die Schwimmaufbereitung der Erze (Vageler, book rev.).....	2482
Foods, conversion of grain straw and lupine to, of higher value, 2127; org.....	2127
Formaldehyde, distn. of aq. solns. of, 695; reaction between, and water, 1671; action of PH <sub>3</sub> on. 1684	
Formamidines, reactions of the.....	613, 1200
Formates, compd. formation and soly. in systems of the type, formic acid: metal formates 1470; compd. formation and cond. in systems of the type formic acid: metal formates.....	1846
Formic acid, compd. formation and soly. in systems of type, : metal formate, 1470; compd. formation and cond. in systems of the type, : metal formate.....	1846
Freezing points, effect of finely divided material on the, of H <sub>2</sub> O, C <sub>6</sub> H <sub>6</sub> , and nitrobenzene.....	1011
Friedel and Crafts' reaction.....	213, 1920, 1950, 1965, 2577
Fructose, optical rotation of mixts. of sucrose, glucose and.....	219
Fruit juices, detection of methyl anthranilate in.....	377
<b>GALLIUM</b> , 274; recovery from its ferrocyanide salt, 113; sepn. from In and Zn.....	126
Gallium ferrocyanide, use in analysis.....	111

Gases, mass effect in the entropy of, 818; similitude principle and the entropy of polyatomic, 866; obliteration of the characteristic spectra of metals by certain, 1255; adsorption by metallic catalysts, 1273; adsorption by solid bodies.....	2127
Gelatin, zone of max. colloidal—its relation to viscosity in hydrophilic colloids, especially, 434; elastic properties of, jellies, 539; osmosis and swelling of, 1350; viscosity of, solns., 1526; viscosity of, sols, 1764; influence on the transference numbers of $H_2SO_4$ .....	2161
Germanium, at. wt. of, 1085; ext. from $ZnO$ —non-occurrence in samarskite, 2131; sepn. of As and.....	2549
Glass, devitrification of—repair of crystd., app., 11; repair of crystd., app.....	1319
Glassblowing, $C_2H_2$ in.....	1310
<i>d</i> -Glucose, optical rotation of mixts. of sucrose, fructose and, 219; influence on the dialysis of sucrose through a parchment membrane—sepn. of, from sucrose by dialysis.....	2588
Glucosides, Anleitung zum Nachweis, zur Trennung und Bestimmung der reinen und aus Glukosiden usw. erhaltenen Monosaccharide und Aldehydsäuren (van der Haar, book rev.).....	685
Gold alloys, structure of Au amalgams.....	740
Grape juice, occurrence of Me anthranilate in.....	1741
Gravitation, simple application of Newton's law of, to globular star clusters.....	2127
Guanidine nitrate, prepn. of.....	2234
<b>HALOGEN</b> , existence and reactions of positive, attached to C in aromatic compds.....	2081
Halogenation, replacement of sulfonic acid groups by halogens.....	303
Heat, mol., of H, 23; radiation theory of thermal reactions.....	1288
Heating coils, immersion, of low lag.....	470
Heat of coagulation, of $Fe_2O_3$ hydrosol with electrolytes.....	2336
Heat of dilution, of dil. solns. of $HNO_3$ and of hydroxides and chlorides and nitrates of Li, Na, K, and Cs.....	770
Heat of formation, of $AgI$ .....	2014
Heat of solution, of the acido and aquo Co pentammines.....	2188
Heat of transformation, of the acido and aquo Co pentammines.....	2188
Heat of wetting, of Si gel.....	2144
Hexa-aquo chromic chloride, hydrolysis of.....	1154
Histidine, influence on the hydrolysis of starch by purified pancreatic amylase.....	2469
History, of Chemistry from the Earliest Times (Brown, book rev.), 215; der Organischen Chemie (Graebe, book rev.).....	1382
Hofmann rearrangement, in mercuri-org. derivs.....	1838
Hydrates, detn. of the vapor pressure of salt.....	704, 726
Hydration, of sucrose in water soln. as calcd. from vapor-pressure measurements.....	2406
Hydrazines, prepn. of optically active.....	2682
Hydriodic acid, electro-titration of, and its use as a standard in oxidimetry.....	14
Hydrocarbons, some phys. properties of, contg. 2 and 3 C atoms, 1098; Friedel and Crafts' reaction—carbomethoxy-benzoyl chlorides with aromatic, and $AlCl_3$ .....	1920
Hydrogen, mol. heat of, 23; reduction of $CuO$ by.....	2179
Hydrogen chloride, elimination from chlorohydrocarbons.....	1715
Hydrogen peroxide, non-addition of, to diphenylketene.....	935
Hydrogen persulfides, prepn. and properties of.....	2539
Hydrolysis, rates of, of the rare earth carbonates.....	1446
Hydroquinone, oxidation and reduction of, from the standpoint of e. m. f. measurements.....	1401
Hydroxamic acids, rearrangements of some new, related to heterocyclic acids and to diphenyl- and triphenyl-acetic acids.....	2422
Hydroxylamine, structures and reactions of, and its derivs.....	315
2,4-Hydroxy-3-methoxystyrylquinoline, an alkylene and some alkyl halides of.....	890
Hydroxynaphthoquinone, studies.....	2582
<i>p</i> -Hydroxy- <i>m</i> -nitrophenylcarbinol, Hg deriv. of.....	1203
<b>INDIUM</b> , sepn. of Ga from.....	126
Infections, biol. equil. in.....	2127
Interfacial tension.....	35
Interferometer, water, as a pressure gage, 2497; osmotic pressures of concd. solns. of sucrose as detd. by the water.....	2501
Invertase, some errors in the study of, action, 1693; activity of adsorbed, 1956; uniformity in, action.....	2632
Iodic acid, detn. of.....	858
Iodine, action on the Na salt of trichlorophenol.....	151

Ionization, electrolytic, factors affecting the stability of addition compds. in soln. and their influence upon, equilibria, 1416; of aq. solns of $\text{NH}_3$ in the presence of urea.....	1632
Ionization, gaseous, thermal ionization of metallic vapors.....	1630
Ions, electrolytic, ion mobilities, ion conductances, and the effect of viscosity on the conductances of certain salts, 1217; free energy of diln. and the activities of the, of $\text{KBr}$ in aq. solns.....	2483
Iron, detn. of, 91, 847, 1560; influence of $\text{Cu}$ on the rate of soln. of, in acids, 452; allotropy of.....	1884
Iron nitride, dissociation pressures of.....	475
Iron oxides, action of $\text{Na}_2\text{S}$ on $\text{Fe}_2\text{O}_3$ , 734; heat of coagulation of $\text{Fe}_2\text{O}_3$ hydrosol with electrolytes....	2336
Iron salts, reduction of solns. of ferric salts with $\text{Hg}$ .....	2372
Isoamyl alcohol, sepn. of, and water.....	368
Isobutyl alcohol, purification and some phys. properties of.....	561
Isobutyl-cyano-acetic acid.....	672
Isomerism, theory of chromo-, of solid compds.....	1654
Isopropyl alcohol, purification and some phys. properties of, 561; properties of mixts. of $\text{H}_2\text{O}$ and....	1005
Isotopes, natural systems for the classification of, and the at. wts. of pure at. species as related to nuclear stability, 1038; sepn. of $\text{Cl}$ into.....	1803
Isotopy, of mesothorium and $\text{Ra}$ .....	440
<b>JELLIES</b> , elastic properties of gelatin.....	539
Joule-Thomson effect, for air.....	1452
<b>KAISER</b> Wilhelm Gesellschaft zur Förderung der Wissenschaften, Festschrift der (book rev.)....	2127
Karaya <sup>gum</sup> , zone of max. colloidal—its relation to viscosity in hydrophilic colloids, especially....	434
Ketones, compd. formation and sp. cond. in solns. of the types acid-, 1426; compd. formation and viscosity in solns. of the types acid-, 1826; action of $\text{PCl}_3$ on satd.....	1928
Kinetics, statistical mechanics applied to chem. (correction).....	126
<b>LANTHANUM</b> , revision of the at. wt. of.....	1080
Lanthanum chloride, analysis of.....	1080
Laws, application of Victor Meyer's esterification law to 2,6-xylic acid and its reduced derivs....	925
Lead, surface tension and density of liquid.....	1621
Lead salts, quant. sepn. of, of the satd. from the less unsatd. fatty acids.....	1323
Light, ultra-violet, action on colloidal $\text{Pt}$ .....	1385
Linolic acid tetrabromide, non-identity of eleostearic acid tetrabromide from tung oil with ordinary.....	938
Lipase, castor bean.....	2664
Liquids, viscosity of, 116; La Tension de Vapeur de Mélanges de (Lecat, book rev.).....	1745
Lithium chloride, heat of diln. and the sp. heat of dil. solns. of.....	770
Lithium hydroxide, heat of diln. and the sp. heat of dil. solns. of.....	770
Lithium nitrate, heat of diln. and the sp. heat of dil. solns. of, 770; vapor pressure of, : $\text{NH}_3$ system.....	1575
Lobinol.....	159
Long, John Harper, (Gault, book rev.).....	2125
Lupines, conversion to foodstuff of higher value.....	2127
<b>MANGANATE</b> , equil. conditions of the reaction between permanganate, $\text{MnO}_2$ and.....	294
Manganese, in the catalytic oxidation of $\text{NH}_3$ .....	2034
Manganese dioxide, equil. conditions of the reaction between manganate, permanganate and....	294
Mass effect, in the entropy of solids and gases.....	818
Mathematical functions, Some (Kaye, Laby, book rev.).....	2258
Mechanics, statistical, applied to chem. kinetics (correction), 126; statistical, and chemistry....	1251
Medicines. See <i>Pharmaceutical preparations</i> .	
Meleagris gallopavo, enzymes of the abdominal adipose tissue of.....	1963
Melting point, use of $\text{H}_3\text{PO}_4$ in detn. of, of org. solids, 212; detn. of, of certain hydrocarbons....	1100
Membrane, influence of glucose on the dialysis of sucrose through a parchment.....	2588
Mercaptans, catalytic prepn. of, 880; iodometric estn. of.....	1199
2-Mercaptopyrimidines, alkylation of.....	2603
5,5'-Mercuri-bis-3-nitro-4-hydroxyphenylarsonic acid, prepn. of.....	1185
Mercuric iodide, some derivs. of butyl mercaptan and their, compds.....	638
Mercuric nitrate, role of, in the "catalyzed" nitration of aromatic substances.....	594
Mercuric oxide, catalytic influence of foreign oxides on the decompn. of.....	2017
Mercurization, of aromatic amines.....	1894
Mercurous chloride, satd. $\text{KCl}$ calomel cell (correction).....	302
Mercury, action on tribromophenol bromide, 131; surface tension and density of liquid, 1621; nature of valences of, in mercuri-org. derivs., 1888; reduction of solns. of ferric salts with....	2372

Mercury compounds, mercuri-org. derivs.—nitrobenzene Hg compds.—indirect method of mercurizing org. compds., 607; reaction of alkali metal halides with Hg derivs. of phenol, 619; deriv. of <i>p</i> -hydroxy- <i>m</i> -nitrophenylcarbinol, 1203; aromatic, Hofmann rearrangement and the nature of valences of Hg in, 1888; mercurization of aromatic amines and its relation to the theory of substitution, 1894; prepn. of org. ....	2238
Mercury salts, in the catalytic transformation of acetylene into acetaldehyde. ....	2071
Mesitol, prepn. and oxidation of. ....	1194
Mesothorium, isotopism of Ra and, and its sepn. from Ba. ....	440
Metabolism, Die Biogenen Amine und ihre Bedeutung für die Physiologie und Pathologie des Pflanzlichen und Tierischen Stoffwechsels (Guggenheim, book rev.), 2129; Physiology of Protein (Cathcart, book rev.). ....	2482
Metals, solns. of, in non-metallic solvents, 749; obliteration of the characteristic spectra of, by certain gases, 1255; thermal ionization of metallic vapors. ....	1630
Metaskolecite. ....	381
Methyl alcohol, reaction between, and water and some related reactions. ....	1670
4-Methylbenzophenone chloride, and its condensation with phenol. ....	175
Methylisobutylcarbinol, purification and some phys. properties of. ....	561
2-Methylpyridine. ....	1937
3-Methylpyridine. ....	1937
Micro-photometer. ....	532
Mix-crystals, existence of $\text{Na}_2\text{SO}_4 \cdot 4\text{H}_2\text{O}$ in, with $\text{Na}_2\text{CrO}_4$ . ....	1543
Molecular attraction. ....	35
Molecular volumes, analysis of, from the point of view of the Lewis-Langmuir theory of mol. structure. ....	991
Molecules, orientation in surfaces, 35, analysis of mol. vols. from the point of view of the Lewis-Langmuir theory of mol. structure, 991; Langmuir's theory of the arrangement of electrons in. ....	1602
Molybdenum, sepn. of W and. ....	2383
Monazite, detn. of Th in, sand. ....	2003
Monosaccharides, Anleitung zum Nachweis, zur Trennung und Bestimmung der reinen und aus Glukosiden usw. erhaltenen Monosaccharide und Aldehydsäuren (van der Haar, book rev.). ....	685
Monzonites. ....	381
<b>NEOARSPHENAMINE</b> , examn. of. ....	643
Nephelometer. ....	532
Nephritis (Fischer, book rev.). ....	2262
Nesslerization, of $\text{NH}_3$ solns. ....	2574
Nickel, comparison of the at. wts. of terrestrial and meteoric, 507; allotropy of. ....	1884, 1887
Nickel ores, formation of siliceous. ....	381
Nickelous oxide, reduction of. ....	507
Nitration, role of $\text{Hg}(\text{NO}_3)_2$ in the "catalyzed," of aromatic substances. ....	594
Nitric acid, equil. between $\text{NO}$ , $\text{NO}_2$ and aq. soln. of, 518; heat of diln. and the sp. heat of dil. solns. of, 770; vapor pressures of aq. solns. of. ....	1782
Nitric oxide, equil. between $\text{NO}$ , aq. soln. of $\text{HNO}_3$ and. ....	518
Nitrides, (Maxted, book rev.). ....	1747
Nitrite ion, electrometric detn. of. ....	1309
Nitro-anilines, ethers derived from the addition products of the, and chloral. ....	941
<i>p</i> -Nitrobenzaldehyde, derivs. of. ....	625
Nitrobenzene, Hg compds., 607; effect of finely divided material on the f. p. of. ....	1011
<i>p</i> -Nitrobenzyl mercaptan, chemistry of. ....	2610
Nitrogen, distribution in the alfalfa seed, 906; Die Reaktionen des freien Stickstoffs (Moldenhauer, book rev.), 963; conduct of mixts. of, and Cl in a flaming arc. ....	1774
Nitrogen compounds, in alfalfa hay. ....	2656
Nitrogen pentoxide, thermal decompn. of gaseous, 53; photochem. decompn. of. ....	72
Nitrogen peroxide, reaction between Cu and, 494; equil. between $\text{NO}$ , aq. soln. of $\text{HNO}_3$ and. ....	518
Nitrogen trichloride, chlorination and the formation of chloro-amines by means of. ....	2211
3-Nitro-4-hydroxy-5-iodobenzoic acid. ....	1203
5-Nitro-4-hydroxy-3-methylbenzoic acid. ....	375
Nitromalic acid. ....	2084
Nitro-nitrogen trichloride, attempt to prepare. ....	1774
Nitroso R-salt. ....	746
Nitrotartaric acid. ....	577
<b>OAK</b> poison, lobinol from. ....	159
Oleic acid, relation to its halogen addition products. ....	2122

Optical rotation, of mixts. of sucrose, <i>d</i> -glucose and fructose.....	219
Ores, Die Schwimmaufbereitung der (Vageler, book rev.).....	2482
Organic chemistry, Lab. Expts. in (Cook, book rev.), 964; Geschichte der (Graebe, book rev.)...	1382
Organic compounds, estn. of As in, 182; Org. Chem. Reagents (II) (Adams, Kamm, Marvel, book rev.), 1748; existence and reactions of positive halogen attached to C in aromatic, 2081; Organic Syntheses (Adams, Clarke, Conant, Kamm, book rev.).....	2702
Osmosis, and the swelling of gelatin.....	1350
Osmotic pressures, of concd. solns. of sucrose.....	2501
Otoba butter, analysis of.....	199
Oxalic acid, prepn. of anhydrous.....	368
Oxidation, catalytic, of CO, 1973, 1982; Mn in the catalytic, of NH <sub>3</sub> .....	2034
Oxides, constitution of amorphous, 135; catalytic influence of foreign, on the decompn. of Ag <sub>2</sub> O, HgO and BaO <sub>2</sub> .....	2017
Oxidimetry, HI as a standard in.....	14
Oxygen, system, Cu-CuO-, 1061; univalent.....	1194
Oxynitrilase, properties of.....	164
Ozone, oxidation of CO by passage with O or air over O <sub>3</sub> -decomp. catalysts.....	967
<b>PAPRIKAS</b> , changes in the compn. of, during the growing period.....	2101
Paraldehyde, manuf. of.....	2071
Parchment, influence of glucose on the dialysis of sucrose through a membrane.....	2588
Partition, distribution of a strong electrolyte between benzene and water.....	254
Peaches, odorous constituents of.....	1725
Peanut oil, chem. compn. of.....	1372
Pentabromophenol, chromo-isomeric Ag salts of.....	1654
Perchloromethylmercaptan.....	591
Permanganate, equil. conditions of the reaction between manganate, MnO <sub>2</sub> and.....	294
Pharmaceutical preparations, Qual. Analysis of Medicinal Preps. (Fuller, book rev.), 1212; Chemistry and Analysis of Drugs and Medicines (Fuller, book rev.), 1213; Chemistry of Synthetic Drugs (May, book rev.), 1970; Org. Medicinal Chemicals (Synthetic and Natural), (Barrowcliff, Carr, book rev.), 1970; distribution of certain drugs between immiscible solvents.....	2323
Pharmacognosy, Scientific and Applied (Kraemer, book rev.).....	1210
Phase theory, Principles of the (Clibbens, book rev.).....	2259
Phenacyl esters, sepn. of acids by means of.....	629
Phenanthrene, detn. of.....	1911
9(10)-Phenanthridone, prepn. from phenanthrene.....	208
Phenol, catalytic decompn. of certain phenol Ag salts, 131, 135, 151; 4-methylbenzophenone chloride and its condensation with, 175; interaction of Sn and, 211; reaction of alkali metal halides with Hg derivs. of, 619; compd. formation in mixts. with cresol.....	1853
Phenoxarsin, some derivs. of.....	891
Phenylacetic- <i>p</i> -arsonic acid.....	179
5-Phenyl-4-pyrazolecarboxylic acid, synthesis of.....	1200
2-Phenylquinoline-4-carboxylic acid-6-arsonic acid.....	2255
Phenylthioxanthyl.....	1940
Phosphenyl chloride, 1,4-addition of.....	1665
Phosphine, action on CH <sub>2</sub> O.....	1684
Phosphoric acid, use in m. p. detns. of org. solids.....	212
Phosphorus, vapor pressure of white, from 44° to 150°, 547; allotropy of.....	1875
Phosphorus halides, addition reactions of.....	1665, 1677, 1928
Phosphorus tribromide, addition to benzalacetophenone.....	1713
Phosphorus trichloride, equil. between, and benzalacetophenone, 1712; action on satd. aldehydes and ketones.....	1928
Photochemistry, Allgemeine (Plotnikow, book rev.).....	2260
Photometry, photometric methods and app. for the study of colloids.....	531
Phototropism, in soln.....	333
Phthalate buffers—some incompatibilities.....	914
Phthalic acid, soly. in H <sub>2</sub> O and Na <sub>2</sub> SO <sub>4</sub> solns.....	1205
Phthalic anhydrides, Friedel and Crafts' reaction—some substituted, with toluene and AlCl <sub>3</sub> ....	2577
Physical chemistry, Text-book of, (Lincoln, book rev.), 687; for Colleges (Millard, book rev.), 2477; Physik- alisch-chemische Uebungen (Roth, book rev.).....	2477
Physical constants, Tables of (Kaye, Laby, book rev.).....	2258
Picric acid, oxidation by HNO <sub>3</sub> .....	605
Piperidine, some compds. of, with halides.....	2618
Plants, Chemistry of Plant Life (Tatcher, book rev.).....	1214
Platinum, prepn. of pure, 1268; action of ultra-violet light on colloidal.....	1385

Polarimetry, Na lamp for.....	1629
Potassium, conductance of cond. solns. of, in liquid $\text{NH}_3$ .....	2529
Potassium bromide, free energy of diln. and the activities of the ions of, in aq. solns.....	2483
Potassium chloride, lowering of the vapor pressure of water at $20^\circ$ produced by dissolved, 102; satd., calomel cell (correction), 302; heat of diln. and the sp. heat of dil. solns. of.....	770
Potassium hydroxide, heat of diln. and the sp. heat of dil. solns. of, 770; influence on the formation of vinyl alc. from $\text{CH}_3\text{CHO}$ .....	1925
Potassium nitrate, heat of diln. and the sp. heat of dil. solns. of.....	770
Potential, electric, oxidation and reduction of hydroquinone and quinone from the standpoint of e. m. f. measurements, 1401; at the junctions of monovalent chloride solns.....	2563
Pressure, thermodynamic relation between soly. and internal, 500; high, due to adsorption, 1787; water interferometer as a, gage.....	2497
Priestley, in America, 1794-1804 (Smith, book rev.).....	1967
Propane, some phys. properties of.....	1098
Propyl alcohol, purification and some phys. properties of, 561; conductance of solns. of ternary electrolytes in.....	1568
Propylene, some phys. properties of.....	1098
Proteins, purifying certain kinds of, 687; application of the Van Slyke method to hydrolyzed, exts. of silage crops, 951; Physiology of, Metabolism (Cathcart, book rev.).....	2482
Pyridine, some phys. properties of aq. solns. of certain, bases, 1867; prepn. of, and of certain of its homologs in a state of purity.....	1936
Pyrimidines.....	2603, 2670
<b>QUINONE</b> , oxidation and reduction of, from the standpoint of e. m. f. measurements.....	1401
<b>RADIATION</b> , theory of thermal reactions.....	1288
Radioactivity, Radioaktivitaet (Meyer, v. Schweidler, book rev.), 213; disintegration series.....	2127
Radium, isotopism of mesothorium and, and its sepn. from Ba, 440; adsorption by $\text{BaSO}_4$ .....	1615
Rare earth carbonates, rates of hydrolysis of the.....	1446
Rare earth elements, rates of hydrolysis of the rare earth carbonates and the serial order of the.....	1446
$\alpha$ -Rays, Chem. Effects of (Lind, book rev.).....	1966
Rays, Röntgen, detn. of crystal structure by, 381; Zur Feier der Entdeckung der, vor fünfundzwanzig Jahren (book rev.).....	959
Reactions, theory of monomol., 269; Chem., Their Theory and Mechanism (Falk, book rev.), 690; periodic, in homogeneous soln. and its relation to catalysis, 1262; radiation theory of thermal.....	1288
Reaction velocity, calcn. of, 397; in concd. solns.....	2387
Reactivity, theory of chem., 397; and conductance of $\text{C}_6\text{H}_5$ solns.....	646
Reagents, Org. Chem., (Adams, Kamm, Marvel, book rev.).....	1748
Reduction, of solns. of ferric salts with $\text{Hg}$ .....	2372
Research, Notes on Chem. (Dreaper, book rev.).....	1383
Resorcinol, prepn. of some alkyl derivs. of, and the relation of their structure to antiseptic properties.....	348
Respiration, physical chemistry of cellular.....	2127
Rhamnose, prepn. of.....	127
Rhus diversiloba, lobinol from.....	159
Rubidium bromate, prepn. and study of.....	2031
<b>SACCHARINIC acids</b> , Ca.....	2675
Saligenin, some derivs. of.....	1688
Salts, detn. of the vapor pressure of salt-hydrates, 704, 726; effect of viscosity on the conductances of certain, 1217; vapor pressure of $\text{NH}_3$ -salt solns., 1580; soly. of metal $\text{NH}_3$ salts in salt solns.....	2265
Samarskite, non-occurrence of Ge in.....	2131
Sands, asphalt in the tar, of Northern Alberta.....	1337
Sauerkraut, influence of certain factors upon the chem. compn. of.....	2244
Science, and economics.....	2127
Selenium oxychloride, some properties of, 29; sepn. of Cb and Ta by means of, 2378; sepn. of Mo and W by means of.....	2383
Separator, automatic, in esterifications and other prepn.s.....	366
Silage, application of the Van Slyke method to hydrolyzed protein exts. of, crops.....	951
Silica, heat of wetting of, gel.....	2144
Silicic acid, 391; organogels of.....	1844
Silver, use of the, cathode in electro-deposition of Cu, 700; detn. of.....	858
Silver bromate.....	1440
Silver chloride, soly. of, in dil. chloride solns. and the existence of complex argentichloride ions..	2492
Silver iodide, heat of formation of.....	2014

Silver oxide, catalytic influence of foreign oxides on the decompn. of.....	2017
Silver salts, catalytic decompn. of certain phenol Ag salts, 131, 135, 151; chromo-isomeric, of pentabromophenol.....	1654
Similitude principle.....	866
Skolecite.....	381
Sodium, conductance of concd. solns. of, in liquid $\text{NH}_3$ .....	2529
Sodium amide.....	586
Sodium bromate, crystal structure of.....	2045
Sodium chlorate, crystal structure of.....	2045
Sodium chloride, heat of diln. and the sp. heat of dil. solns of.....	770
Sodium chromate, existence of $\text{Na}_2\text{SO}_4 \cdot 4\text{H}_2\text{O}$ in mix-crystals with.....	1543
Sodium hydroxide, heat of diln. and the sp. heat of dil. solns. of, 770; prepn. of, free from $\text{CO}_2$ .....	2573
Sodium hyposulfite, estn. of.....	1307
Sodium lamp, for polarimetry.....	1629
Sodium nitrate, heat of diln. and the sp. heat of dil. solns. of.....	770
Sodium phenolate, chemistry of, fusions.....	2127
Sodium sulfate, soly. of phthalic acid in, solns., 1205; existence of tetrahydrated, in mix-crystals with $\text{Na}_2\text{CrO}_4$ .....	1543
Sodium sulfide, action on $\text{Fe}_2\text{O}_3$ .....	784
Solids, mass effect in the entropy of.....	818
Solubility, thermodynamic relation between, and internal pressure, 500; compd. formation and, in systems of the type $\text{H}_2\text{SO}_4$ : metal sulfate, 979; compd. formation and, in systems of the type, formic acid: metal formate, 1470; prediction in polar solns., 1481; of acids in aq. solns. of other acids, 1545; in mixts. of 2 solvents, 1753; relations of rhombic S, 2172; of metal $\text{NH}_3$ salts in salt solns.....	2265
Solutions, thermodynamic treatment of concd., 233; phototropism in, 333; reactivity and conductance of benzene, 646; of metals in non-metallic solvents, 749; application of ideal soln equations to dil. aq., 1391; factors affecting the stability of addition compds. in, 1416; compd. formation and sp. cond. in, of the types acid: ester, acid: ketone and acid: acid, 1426; prediction of soly. in polar, 1481; conductance of, of ternary electrolytes in propyl alc., 1568; compd. formation and viscosity in, of the types acid: ester, acid: ketone, and acid: acid, 1826; soly. of metal $\text{NH}_3$ salts in salt, 2265; speed of reaction in concd., 2387; Ghosh's theory of electrolytic.....	2514
Solvents, solubilities in mixts. of two, 1753; distribution of certain drugs between immiscible....	2323
Specific heats, heats of diln. and the, of dil. solns. of $\text{HNO}_3$ and of hydroxides and chlorides and nitrates of Li, Na, K, and Cs.....	770
Spectra, obliteration of the characteristic, of metals by certain gases.....	1255
Spiro-pyrimidines.....	677, 1366, 2097
Starch, influence of certain amino acids on the enzymic hydrolysis of, 2461; influence of arginine, histidine, tryptophan and cystine on the hydrolysis of, by purified pancreatic amylase.....	2469
Star clusters, application of Newton's law of gravitation to globular.....	2127
Steam, catalysis in the interaction of C with.....	2055
Straw, conversion of grain, to foodstuff of higher value.....	2127
Substitution, mercurization of aromatic amines and its relation to the theory of.....	1894
Sucrose, optical rotation of mixts. of glucose, fructose and, 219; velocity of sugar hydrolysis, 1759; mechanism of the inversion of, 2387; hydration of, in water soln. as calcd. from vapor-pressure measurements, 2406; osmotic pressures of concd. solns. of, 2501; influence of glucose on the dialysis of, through a parchment membrane—sepn. of glucose from, by dialysis.....	2588
Sugars, conditions affecting the detn. of reducing, by Fehling soln.....	1503
Sulfates, compd. formation and soly. in systems of the type $\text{H}_2\text{SO}_4$ : metal sulfate, 979, compd. formation and cond. in systems of the type $\text{H}_2\text{SO}_4$ : metal sulfate.....	1846
Sulfide, volumetric detn. of.....	1610
Sulfide alcohol.....	636
Sulfonic acid groups, replacement by halogens.....	303
2,2'-Sulfonidotriphenylmethyl.....	1945
Sulfur, soly. relations of rhombic.....	2172
Sulfuric acid, action on dicyanodiamide, 669; compd. formation and soly. in systems of the type metal sulfate, 979; compd. formation and cond. in systems of the type metal sulfate, 1846; transference numbers of, by the concn. cell method, 2150; influence of gelatin on the transference numbers of.....	2161
Surface energy.....	35, 1787
Surface forces.....	1787
Surface tension, capillary rise method of detg., with data for $\text{H}_2\text{O}$ , $\text{C}_6\text{H}_6$ , toluene, $\text{CHCl}_3$ , $\text{CCl}_4$ , ether, and dimethylaniline, 827; detn. of, of certain hydrocarbons, 1107; of liquid Hg, Cd, Zn, Pb, Sn and Bi.....	1621

Swelling, osmosis and, of gelatin.....	1350
<b>TANTALUM</b> , sepn. of Cb and.....	2378
Tar, asphalt in the, sands of Northern Alberta.....	1337
Tartronic acid, dimethyl ester of.....	628
Tensile energy.....	35
Tensile strength.....	35
Tetrapropylethane.....	2626
Thallium alloys, thermodynamic treatment of concd. solns., and applications to Tl amalgams...	233
Thermochemistry, thermochem. data of CdCl <sub>2</sub> and CdI <sub>2</sub> .....	484
Thermodynamics, thermodynamic treatment of concd. solns. and applications to Tl amalgams, 233; relation between soly. and internal pressure.....	500
Thermometers, construction of Pt resistance, 470; differential, 2309; application of a differential, in ebullioscopy.....	2314
Thiazolidone, some, derivs. of the formamidines.....	613
Thio-ethers, derivs. of anthraquinone.....	2104
Thio-ether sulfonic acids, derivs. of anthraquinone.....	2104
Thorium, detn. in monazite sand.....	2003
Thymine, identifying.....	2670
Tin, interaction of phenol and, 211; surface tension and density of liquid.....	1621
Titanium, trivalent.....	91
Toluene, reaction with HNO <sub>3</sub> contg. Hg, 600; surface tension data for, 827; Friedel and Crafts' reaction—some substituted phthalic anhydrides with, and AlCl <sub>3</sub> .....	2577
2- <i>p</i> -Toluybenzoic acid, prepn. of.....	1965
2,3,8-Tribromo-5-hydroxy-1,4-naphthoquinone, derivs. of.....	2582
Tribromophenol bromide, action of Hg on.....	131
Trichlorophenol, action of I on the Na salt of.....	151
Trihalogen-methyl reactions.....	700
Trimethylene chlorohydrin, prepn. of.....	369
Trimethylphosphine, and its selenide.....	916
Trimethylphosphine selenide.....	916
2,4,6-Trinitrobenzaldehyde, derivs. of.....	341, 1961
Triphenylacetic acid, rearrangements of some new hydroxamic acids related to.....	2422
Tryptophan, influence on the hydrolysis of starch by purified pancreatic amylase.....	2469
Tung oil, eleostearic acid tetrabromide from.....	938
Tungsten, sepn. of Mo and.....	2383
Turkey, enzymes of the abdominal adipose tissue of the common.....	1963
<b>UNSATURATION</b> , and mol. compd. formation.....	1227
Uranium, qual. sepn. and detection of V, Cr and, when present together, 114; new active substance in.....	2127
Urea, ionization of aq. solns. of NH <sub>3</sub> in the presence of.....	1632
Ureas, condensation of cyclopropane-1,1-dicarboxylic ester with.....	2097
<b>VALENCE</b> , addition reactions of the carbonyl group involving the increase in, of a single atom, 1705; nature of, of Hg in mercuri-organic derivs., 1883; addition reactions of the carbonyl group involving the increase in, of a single atom (correction).....	2125
Vanadic acid, co-pptn. of, with NH <sub>4</sub> phosphomolybdate.....	2552
Vanadium, qual. sepn. and detection of U, Cr, and, when present together, 114; detn. of, after reduction by H <sub>2</sub> S.....	1560
Vapor pressure, lowering of, of water at 20° produced by dissolved KCl, 102; of white P from 44° to 150°, 547; detn. of the, of salt-hydrates, 704, 726; detn. of, of certain hydrocarbons, 1101; of LiNO <sub>3</sub> : NH <sub>3</sub> system, 1575; of NH <sub>3</sub> -salt solns., 1580; des Mélanges de Liquides: L'Azoétropisme (Lecat, book rev.), 1745; of aq. solns. of HNO <sub>3</sub> , 1782; hydration of sucrose in water soln. as calcd. from, measurements.....	2406
Vinyl alcohol, influence of KOH on the formation of, from CH <sub>3</sub> CHO.....	1925
Viscosity, of liquids, 115; zone of max. colloidal—its relation to, in hydrophile colloids, 434; effect on the conductances of certain salts, 1217; of gelatin solns., 1526; of gelatin sols, 1764; compd. formation and, in solns. of the types acid: ester, acid: ketone, and acid: acid.....	1826
Vitamins, role in the growth of yeast, 186; (Harrow book rev.).....	1749
<b>WATER</b> , lowering of the vapor pressure of, at 20° produced by KCl, 102; distribution of a strong electrolyte between benzene and, 254; surface tension of, 827; properties of mixts. of isopropyl alc. and, 1005; effect of finely divided material on the f. p. of, 1011; equil. in the system NH <sub>3</sub> : NH <sub>4</sub> CNS; 1031; reaction between Me alc. and, 1670; reaction between CH <sub>2</sub> O and.....	1671
Water vapor, mol. state of.....	851

2,6- <b>X</b> YLIC acid, application of Victor Meyer's esterification law to, and its reduced derivs. ....	925
<b>Y</b> EAST, nutritional requirements of— (I) role of vitamins in the growth of, 186; nutritional requirements of—(II) effect of the compn. of the medium on the growth of.....	191
<b>Z</b> INC, electrode, observations on, 81; sepn. of Ga from, 126; revision of the at. wt. of—detn. in ZnCl <sub>2</sub> , 1242; surface tension and density of liquid.....	1621
Zinc chloride, detn. of Zn in.....	1242
Zinc oxide, Ge extn. from.....	2131

PROCEEDINGS

OF THE

American Chemical Society

---

FOR THE YEAR 1921

---

EASTON, PA.  
ESCHENBACH PRINTING COMPANY  
1921

# PROCEEDINGS.

## Contents.

### January.

Directors' Minutes.....	1
Council.....	3
Members Elected between November 15 and December 15, 1920.....	4
Meetings of the Sections:	
California Section.....	11
Some Improvements in Fractional Distillation, S. W. Young. A Short History of the Chlorine Industry, Ludwig Rosenstirn.	
Cincinnati Section.....	11
Standardization of Drugs, F. M. Callender.	
Cleveland Section.....	11
Colorado Section.....	11
The Disruption of the Atoms and the Possibility of Transmutation of the Elements, S. C. Lind.	
Connecticut Valley Section.....	11
The Constitution of Cellulose, Harold Hibbert.	
Cornell Section.....	11
Chemical Botanical Problems, W. W. Rowlee. Chemical Control in the Body, Sutherland Simpson.	
Delaware Section.....	12
Relativity, Joseph S. Ames.	
Eastern New York Section.....	12
A Modified Ionization Theory, James Kendall.	
Georgia Section.....	12
Osmotic Pressure, J. L. McGhee.	
Indiana Section.....	12
Some Problems of the Canning Industry, J. P. Street. Some Things a Chemist Should know about Patents, G. G. Schley.	
Lehigh Valley Section.....	12
New Instruments for Paint Testing, A. H. Pfund. Industrial Microscopy, H. Green. Research Progress, F. G. Breyer.	
Lexington Section.....	12
Oil Shales of Kentucky, C. S. Crouse. A Rapid Method for the Analysis of Dolomite and Magnesian Limestones, S. D. Averitt.	
Louisiana Section.....	12
The Foundations for Chemical Development, Wm. A. Noyes.	
Maryland Section.....	13
Relation of the Chemical Structure of the Opium Alkaloids to their Physiological Action, D. I. Macht. Synthetic Substitutes of the Opium Alkaloids, D. I. Macht.	
Michigan Agricultural College Section.....	13
Milwaukee Section.....	13
Photo-Chemistry, J. D. Mathews.	
Nashville Section.....	13
Atoms and How They are Built, Wm. D. Harkins.	
Nebraska Section.....	13
Some Chemical Problems Peculiar to South Africa, E. Anderson.	

New Haven Section .....	13
The Detection of Small Amounts of Carbon Monoxide, C. R. Hoover.	
New York Section .....	13
The Mechanism of Catalytic Processes, H. S. Taylor.	
Northeastern Section .....	13
The Structure of Protoplasm in the Light of the Electron Theory of Matter, W. T. Bovie.	
Oklahoma Section .....	14
The Foundations for Chemical Development, Wm. A. Noyes. Presidential Address, E. Debarr. The Production of Cylinder Stocks from Oklahoma Crudes, S. Born. The Nitrogen Distribution of the Alkali-Soluble Proteins of Cottonseed Meal, W. G. Friedmann. Milk, E. Debarr. The Preparation of Glycollic Acid, H. I. Jones. Positive and Negative Valence, W. A. Noyes.	
Philadelphia Section .....	14
The Receptivity of Dyes to Proteins, G. Heyl. Arsphenamin, G. W. Raiziss.	
Puget Sound Section .....	14
Phosphorescent Substances, F. R. Heath.	
Rochester Section .....	14
Helium, Its History, Preparation and Uses, R. B. Moore. Measurement and Specification of Color, L. A. Jones.	
Savannah Section .....	14
Report on the Chemical Industries Exposition in New York, V. H. Bassett.	
St. Louis Section .....	15
Vegetable Oil Industries, R. D. Oilar.	
Southeast Texas Section .....	15
The Work of a City Chemist, R. G. Upton.	
South Jersey Section .....	15
Shark Fishing and Shark Leather, A. Rogers.	
Syracuse Section .....	15
The Whitaker-Pritchard Process of Destructive Distillation, T. W. Pritchard. Relativity and Life, Ellwood Hendrick.	
Toledo Section .....	15
Organic versus Inorganic Analysis, O. Kamm.	
University of Illinois Section .....	15
Energy from the Bacteriologist's Viewpoint, F. W. Tanner.	
University of Michigan Section .....	15
Anomalous Osmose and its Relation to the Behavior of Certain Colloid Systems, F. E. Bartell.	
University of Missouri Section .....	15
Reality as a Factor in Research, H. E. Patton.	
Virginia Section .....	16
Architecture of the Atom, G. Edgar. The Physics of Flying, R. E. Loving.	
Washington, D. C., Section .....	16
Petroleum Products, J. P. Lewis. Coal Tar Products, W. M. Rile. Industrial Alcohol, B. R. Tunison. Forest Products, E. C. Sherrard.	
Wisconsin Section .....	16
Commercial Liquefaction and Separation of Gases, F. G. Cottrell. Bacteria as Chemical Reagents, A. I. Kendall.	
Deceased Members .....	16

## February.

Report of the Secretary of the American Chemical Society for the Year 1920.....	17
Report of the Editor of the Journal of the American Chemical Society for the Year 1920.....	20
Report of the Editor of Chemical Abstracts for the Year 1920.....	21
Report of the Editor of the Journal of Industrial and Engineering Chemistry.....	23
Council.....	25
Members Elected between December 15, 1920 and January 15, 1921.....	25
Meetings of the Sections:	
Chicago Section.....	34
Some Present Aspects of Chemistry in the United States, B. F. Lovelace.	
Experimental Tests of the Radiation Hypothesis, F. Daniels.	
Cleveland Section.....	34
Applications of Colloidal Chemistry, H. N. Holmes.	
Detroit Section.....	35
The Relation Between Chemical Analyses and the Quality of Tool Steels, A. F. MacFarland.	
Indiana Section.....	35
Activated Nitrogen, Hydrogen, and Oxygen, F. O. Andereg. A Movement to Establish the Coöperative Relation Between Science and the Industries in Indiana, I. H. Derby.	
Kansas City Section.....	35
History of the Kansas City Section, F. B. Dains. Chemical Control of Bread-Making, C. J. Patterson.	
Lehigh Valley Section.....	35
Louisville Section.....	35
Michigan Agricultural College Section.....	35
Midland Section.....	35
Reminiscences, T. Griswold, Jr.	
Milwaukee Section.....	35
Physical Chemistry, A. Thomas. The Manufacture of Tin Plate, D. M. Buck. The Estimation of Tannin, E. J. Kern.	
Minnesota Section.....	36
The Theory of Color Production, J. Stieglitz. The Chemical Basis of Education, J. F. McClendon.	
Nebraska Section.....	36
New York Section.....	36
New Points of Contact Between University and Industry, W. K. Lewis. Heat Factors of Oil Shale Distillation, R. H. McKee and E. E. Lyder.	
Northeastern Section.....	36
Some Chemical Problems in Bacteriology, J. Bronfenbrenner.	
Omaha Section.....	36
The Dynamics of Catalase Action, A. Morgulis. Some Observations on Corrosion in Boilers, W. M. Barr. Electrometric Filtration, G. Wendt. Sulfur Producing Bacteria, J. T. Myers. Inspection of Oils and Paints, W. G. Haynes.	
Pittsburgh Section.....	37
The Manufacture of Incandescent Tungsten Filament Bulbs, D. MacRae. The Dayton Oil Gas Process, F. C. Binnall. Some Problems in Graphite Crucible Manufacture, R. B. Gilmore.	

Rhode Island Section.....	37
Chemistry for Everyman, E. Hendrick. The Bucher Process as Utilized by the Ordnance Department During the War, N. E. Holt.	
Rochester Section.....	37
Camphor, Natural and Synthetic, W. Webb.	
Savannah Section.....	37
The Economic Loss from Principal Causes of Death in Savannah with Special Reference to Malaria, A. Larsen. The Economic Loss from Syphilis, with Some Remarks on the Methods of Diagnosis of the Disease, V. H. Bassett. The Wassermann Complement Fixation test for Syphilis, D. Secklinger.	
Southeast Texas Section.....	38
St. Louis Section.....	38
The Bearing of Some of the Federal Laws on the Chemical Business, L. G. Blakeslee.	
Syracuse Section.....	38
Methods of Attacking a Research Problem, C. G. Derick.	
University of Michigan Section.....	38
University of Missouri Section.....	36
Coumarin Extraction, R. M. Smith. Carbon Determinations in Plant Tissues, T. E. Friedemann.	
Virginia Section.....	38
Hydrogen-Ion Concentration and its Determination, E. C. L. Miller	
Washington, D. C., Section.....	38
The Third Law of Thermodynamics, R. C. Tolman.	
<b>March.</b>	
Council.....	39
Auditors' Report.....	39
Report of the Treasurer.....	44
Members Elected between January 15 and February 15, 1921.....	47
Meetings of the Sections:	
Ames Section.....	52
The Life and Researches of J. U. Nef, F. Upson.	
California Section.....	52
The Chemical Effect of Alpha Particles, S. C. Lind. Refining of Zinc by Electrolysis, O. C. Ralston.	
Chicago Section.....	53
Home Remedies, P. N. Leech. Phenol Condensation Products, L. V. Redman.	
Cincinnati Section.....	53
A Simple Method of Determining the Refractive Index of a Liquid by Means of a Microscope, O. C. Van Schlichten. On the Nature of Vegetable Tanning, G. D. McLaughlin. The Transition Period in Varnish Manufacture, C. R. Bragdon.	
Cleveland Section.....	53
Pyrometers and High Temperature Measurement, W. Forsythe.	
Colorado Section.....	53
Chemistry in Agriculture of To-day, H. Mendelson.	
Connecticut Valley Section.....	53
Industrial Lighting, H. S. Miner. Some Recent Applications of X-Rays in the Study of Metals, J. S. Shearer.	

Cornell Section.....	53
Heat Insulators, L. B. McMillan. Chemistry and Engineering in American Potash Manufacture, J. E. Teeple.	
Detroit Section.....	54
Synthetic Iron, H. P. Kimber.	
Eastern New York Section.....	54
Helium, Its Production and Uses, G. C. McLennan. Some Problems of Physiological Optics, F. K. Richtmeyer.	
Georgia Section.....	54
The Manufacture of Dynamite and Gelatin, E. M. Symmes.	
Iowa Section.....	54
Electromotive Forces and Free Energy of Dilution of Potassium Bromide H. B. Hart. The Adsorption of Dyes by Pleistocene Clays, J. N. Pearce. Source of Sodium Chloride in Rain and Snow, N. Knight. Animal Utilization of Pentose, E. W. Rockwood. Further Observations of the Migration of Acyl, J. R. Couture and L. C. Raiford.	
Kansas City Section.....	54
Some Aspects of Chemical Manufacture, W. H. Leverett. Chemistry of Salvarsan, R. Brewster. Chemistry in the Last War and in the Next, W. H. Walker.	
Lexington Section.....	54
Preparation and Selection of Crystals for Measurement, F. E. Tuttle. The Microscopic Examination of Feeding Stuffs and Drugs, E. J. Jackson.	
Louisville Section.....	55
The Manufacture of Dynamite and Gelatin, E. M. Symmes.	
Maine Section.....	55
Moving Picture Films, L. J. Waldbauer.	
Maryland Section.....	55
High Power Fluorescence and Phosphorescence and their Relation to Chemical Change, R. W. Wood.	
Midland Section.....	55
The Manufacture of Synthetic Phenol, P. Cottringer.	
Milwaukee Section.....	55
Patents and Their Relation to Chemists and Chemical Industry, C. S. Miner.	
Minnesota Section.....	55
Theory of Adherence of Arsenical Sprays, W. Moore.	
Nashville Section.....	55
The Manufacture of Dynamite and Gelatin, E. M. Symmes.	
Nebraska Section.....	55
Some of the Problems of a State Chemist, W. S. Frisbie. Selenium Oxychloride, V. Lenher.	
New Haven Section.....	56
The Measurement and Significance of Hydrogen-Ion Concentration in Chemical and Biological Work, S. F. Acree.	
Northeastern Section.....	56
The Uses of Silicate of Soda in Industry, J. G. Vail. The Cold Storage of Food in Massachusetts, H. C. Lythgoe.	
North Carolina Section.....	56
The Manufacture of Dynamite and Gelatin, E. M. Symmes.	
Omaha Section.....	56

Philadelphia Section.....	56
The Importance of Organized Science to Chemistry, H. E. Howe. The Dentrifice Problem Viewed from the Standpoint of Recent Chemical Findings, W. J. Gies.	
Pittsburgh Section.....	56
Some Problems in Graphite Crucible Manufacture, R. B. Gilmore.	
Puget Sound Section.....	56
The Chemistry of the Stars, J. F. Plasket.	
Rochester Section.....	57
The Manufacture of Barrels, F. R. Baxter.	
St. Louis Section.....	57
Micro-World of the Atom, A. H. Compton.	
Savannah Section.....	57
The Manufacture of Dynamite and Gelatin, E. M. Symmes. The Fertilizer Industry, E. H. Armstrong. Potash, P. H. Carter. Acid Phosphate, P. McG. Shuey.	
Southern California Section.....	57
100-inch Reflector; its Construction and Some of the Work that is Being Done with it, F. J. Pease.	
Toledo Section.....	57
Sound Wave Photography, D. C. Miller.	
University of Illinois Section.....	57
Some Recent Experiments in Dewatering of Sludges and Slimes, A. M. Buswell. Helium, R. S. Moore.	
University of Michigan Section.....	57
University of Missouri Section.....	58
The Function of Pentosans in Plants, H. D. Hooker, Jr.	
Virginia Section.....	58
The Division of Research Extension and its Relation to Chemistry, H. E. Howe.	
Washington, D. C., Section.....	58
The Present American Fertilizer Industry, W. D. Hurd. Phosphates and Phosphori Acid Production, W. H. Waggaman. The Potash Situation of To-day, F. W. Brown. Nitrogen Resources, Possibilities and Requirements, Capt. D. P. Gaillard. Fertilizer Utilization, Coördination of Soil, Plant and Fertilizer, O. Schreiner. Concentrated Chemical Fertilizers, a Future Prospect, R. O. E. Davis.	
Wisconsin Section.....	58
The Effect of Climate on the Chemical Composition of Plants, W. L. Tottigham.	
Deceased Members.....	58

### April.

Council.....	59
Members Elected between February 15 and March 15, 1921.....	59
Meetings of the Sections:	
Ames Section.....	62
The Distillation of Aqueous Solutions of Formaldehyde, J. A. Wilkinson.	
The Decomposition of Potassium Chlorate, F. E. Brown.	
California Section.....	62
The Ammono Carbonic Acids and Their Salts, E. C. Franklin. Production of Natural Potash Alum, L. Duncan.	

Chicago Section.....	62
What Constitutes a Food? L. B. Mendel.	
Cincinnati Section.....	62
The Solvay Chemical Industries; Their Work in War and Peace, H. W. Jordan.	
Colorado Section.....	62
Some Application of the Electron Theory to Chemistry, R. G. Gustavson.	
Connecticut Valley Section.....	62
Gels and the Application of Colloidal Chemistry, H. N. Holmes.	
Cornell Section.....	62
Poisonous Insects and the Poisons of Insects, O. A. Johannsen.	
Delaware Section.....	62
Science and Disarmament, M. T. Bogert.	
Detroit Section.....	63
The Physical Metallurgy of the Non-ferrous Metals, C. Thieme. The Vitamins, F. O. Taylor.	
Georgia Section.....	63
Rainfall, C. G. Adsit.	
Indiana Section.....	63
The Immediate Needs of Chemistry in America, W. J. Hale. Chemistry in the Service of Medicine, W. M. Blanchard. Butyl Alcohol and Acetone from Corn, M. E. Nasmith.	
Kansas City Section.....	63
Lexington Section.....	63
The Magnitude of Some Natural Forces. C. A. Shull.	
Louisiana Section.....	63
Louisiana Lignite, R. Glenk.	
Louisville Section.....	63
Michigan Agricultural College Section.....	63
The Electrometric Titration of Oxidation and Reduction Reactions, D. T. Ewing.	
Milwaukee Section.....	64
Some Chemical Facts and Theories of Operative Photography, C. B. Dickey.	
Nashville Section.....	64
The Chemistry and Methods of Wood Preservation, G. E. Marton.	
Nebraska Section.....	64
A New Quantitative Method for the Determination of Potassium in Potash Waters, S. B. Arenson. Acidity of Nebraska Soils, J. C. Russell.	
New Haven Section.....	64
The Coal Industry, R. D. Hall.	
New York Section.....	64
Paint and Rubber Pigments, F. G. Breyer.	
Northeastern Section.....	64
Aluminum and Its Light Alloys, R. S. Williams. Modern Smokeless Powder, T. L. Davis.	
Oklahoma Section.....	64
A Neglected Test for Morphine, G. Y. Williams. Changes in the Composition of the Fat of Peanut-Fed Rabbits during Starvation, C. T. Dowell. Colloid Chemistry and Petroleum, F. A. Padgett. Relations between Granular Electricity, Atomic Structure and Valence, A. F. Reiter. Metallic Soaps, H. I. Jones. The Separation of Caffeine from Cocaine-Allied Alka-	

luids from Syrups Used in Soft Drinks, E. DeBarr. The Manufacture of Alcohols and Other By-Products from Petroleum, S. Born.	
Oregon Section.....	64
The Western Beet Sugar Industry, E. W. Lazell. Some of the Less Common Sugars, H. R. Kelly. Industrial Uses of City Gas, E. L. Hall. Combustible Gases, Their Characteristics and Recent Developments, R. K. Strong.	
Philadelphia Section.....	64
Recent Progress in Organic Chemistry, J. F. Norris. A Glimpse of the Traffic Man's Point of View, W. Martin.	
Pittsburgh Section.....	65
Industrial Microscopy, E. M. Chamot.	
Puget Sound Section.....	65
Efficiency and Economy in the Manufacture, Distribution, and Utilization of Illuminating Gas, G. E. Whitwell.	
Rochester Section.....	65
Where and How the Chemist Helps in an Ordinary Business, E. B. Leary.	
St. Louis Section.....	65
Arsphenamine, H. A. Carlton.	
Savannah Section.....	65
The Economic Position of Cottonseed Oil, B. F. Taylor. By-Product Coke Ovens and the Manufacture of Ammonium Sulfate, A. B. Carmichael.	
Southern California Section.....	65
Structure of the Atom, R. A. Millikan.	
Southeast Texas Section.....	65
The Manufacture of Casing Head Gasoline, F. Seibert. The Transportation of Oil, C. Fitzgerald, Jr.	
South Jersey Section.....	65
Palm Trees as a Commercial Source for Alcohol and Sugar, H. D. Gibbs.	
Syracuse Section.....	65
Principles and Practice of Die Castings, A. G. Carmen. A Modified Ionization Theory, J. Kendall.	
Toledo Section.....	66
Synthetic Phenol Resins, L. V. Redman.	
University of Illinois Section.....	66
The Radiation Hypothesis and Reaction Velocity, F. Daniels.	
University of Michigan Section.....	66
The Constitution and Properties of Boiler Tubes, A. E. White.	
Virginia Section.....	66
Pure Research in the Development of Industrial Catalysis, H. S. Taylor.	
Washington, D. C., Section.....	66
Chemical Crystallography, E. T. Wherry. X-Ray and Crystal Structure, R. W. G. Wyckoff.	
Wisconsin Section.....	66
Some Recent Researches on the Catalytic Decomposition of Hydrogen Peroxide, V. L. Bohnson. Some Micro-Chemical Studies of Steel, D. Fahlberg.	
Deceased Members.....	66
<b>May.</b>	
Minutes of the Directors Meeting.....	67
Council.....	68
Members Elected between March 15 and April 15, 1921.....	68

Meetings of the Sections:

California Section.....	70
The Present Status of Chemical Criteria in the Field of Soil Fertility, J. S. Burd. Experimentation at the Temperature of Liquid Hydrogen, W. M. Latimer.	
Cincinnati Section.....	70
Color Photography, J. H. Mathews.	
Columbus Section.....	70
Photo-Chemistry, J. H. Mathews.	
Cornell Section.....	71
Chemical Problems in Immunity, V. A. Moore.	
Detroit Section.....	71
Photo-Chemistry, J. H. Mathews.	
Eastern New York Section.....	71
X-Rays in Medical Diagnosis, C. B. Welter. Some Electrical Properties of Alloys, M. A. Hunter.	
Indiana Section.....	71
Flotation, E. W. McCullough.	
Lehigh Valley Section.....	71
Early Organic Chemistry in America, E. F. Smith.	
Lexington Section.....	71
The Technique of Atomic Weight Determinations by the Silver Method, O. J. Stewart.	
Louisiana Section.....	71
The Production of American Storax from the Red Gum Tree, S. A. Mahood. Comparison of Wood Cellulose and Cotton Cellulose, S. A. Mahood. Colloidal Chemistry, H. B. Weiser.	
Michigan Agricultural College Section.....	71
Photo-Chemistry, J. H. Mathews.	
Midland Section.....	72
Photo-Chemistry, J. H. Mathews.	
Nashville Section.....	72
New Haven Section.....	72
Scientific Research and the Development of Industrial Catalytic Processes, H. S. Taylor. Rolled Zinc, C. H. Mathewson.	
Northeastern Section.....	72
Publicity, J. W. Harrington. Some Chemical Problems Connected with The Vat Dyes, J. B. Conant. The Enamelling of Sheet Steel, E. P. Stevenson.	
Philadelphia Section.....	72
Recent Developments of the Work of the Bureau of Standards, W. C. Wagner. Refractometry, W. P. Valentine. How to Reach our Friends, the Public, R. Spillane.	
Pittsburgh Section.....	72
Technology of the American Sulfur Industry, R. F. Bacon.	
Puget Sound Section.....	72
Some Chemical Aspects of Electro-Plating, Mrs. Z. J. Gailey.	
Rhode Island Section.....	72
The Manufacture of Starch Glucose and Dextrine from Corn, J. C. Olsen.	
Rochester Section.....	73
Measuring Stars by Light Waves, C. E. K. Mees. Foods and Science, D.

## June.

General Meeting Minutes.....	75
Advisory Committee Minutes.....	75
Council Minutes.....	76
Members Elected between April 15th and May 15th 1921.....	85
Meetings of Sections:	
California Section.....	87
Molecular Rearrangements in Nitrogen Compounds, A. Lachman. Intro- ductory Remarks, A. F. Morgan. Blood Regeneration as Influenced by Dietary Factors, F. S. Robbins. By-Products of Research in Organic Chemistry, H. E. H. Branch.	
Chicago Section.....	87
Photo-Chemistry, J. H. Mathews.	
Connecticut Valley Section.....	87
Water Purification, G. C. Whipple.	
Detroit Section.....	87
The Cottrell Precipitation Process, H. M. Pier.	
Indiana Section.....	87
The Genesis of an Industry, W. Hoskins.	
Iowa Section.....	87
Further Work in the Study of Free Energy of Aqueous Solutions, J. N. Pearce and H. B. Hart. The Effect of Relative Positions of the Hydroxide and Amino Radicals in the Migration of Acyl from Nitrogen to Oxygen,	

L. C. Raiford and H. A. Iddles. A Chemical Study of Dolomites, N. Knight.	
Kansas City Section.....	88
Lehigh Valley Section.....	88
Application of Research to the Coal and Coke Industry, C. O. Brown.	
Lexington Section.....	88
The Work and Purpose of the Bacteriological Division of the Department of Public Service Laboratories, E. J. Gott and J. B. Nelson.	
Louisville Section.....	88
The Chemist as a Business Man, O. Eisenschiml.	
Maine Section.....	88
The Manufacture and Uses of Acid Resisting Clay Products, E. H. Winslow.	
Maryland Section.....	88
The Catalytic Oxidation of Carbon Monoxide, J. C. W. Frazer. The Hydrogen Electrode and Its Application, N. E. Gordon.	
Michigan Agricultural College Section.....	88
Some Recent Immunological Studies, R. L. Kahn. Vitamines in Relation to Plant Life, H. C. Young. Chemical Revolution Effected by Lavoisier and the Early Development of Modern Chemistry, W. G. Smeaton.	
Midland Section.....	88
The Tariff Situation, N. W. Haynes.	
Milwaukee Section.....	88
The Manufacture of Vegetable Oils, G. Pickard. Fatigue of Metals, H. F. Moore.	
Minnesota Section.....	89
Colloid Problems in Baking, R. A. Gortner.	
Nashville Section.....	89
New Developments in the Tennessee Dairy Industry, L. P. Brown. Sanitary Principles in Milk Production, K. C. Davis. Possibilities of Sweet Potato Syrup Manufacture in Tennessee, R. E. Kremers. Report from the Rochester Meeting, G. L. Clark.	
Nebraska Section.....	89
The Acidity of Different Soils, H. C. Russell. Liquid Ammonia and the Ammonia System of Acids, Bases and Salts, E. C. Franklin.	
New Haven Section.....	89
The Bearing of Recent Theories of Atomic Structure on Organic Chemical Reactions, R. Brunel.	
New York Section.....	89
Hoist Machinery in Chemical Industry, E. W. Taylor. Industrial Trucks and Tractors, W. P. Kennedy. Economics in Handling Liquid Coal Tar Products, S. P. Miller. Mechanical Handling of Materials in Large Scale Chemical Operations, A. E. Marshall. Presiding Officer's Address, M. T. Bogert. The Industrial Reconstruction in France, M. Knecht. The Diamond and Its Industrial Uses, G. F. Kunz.	
North Carolina Section.....	89
<i>p</i> -Cymene Studies, II. the Bromination of 2-Amino- <i>p</i> -cymene, A. S. Wheeler and I. W. Smithey. Chlorination with the Silent Electrical Discharge, P. Gross. New Derivatives of 2,3,8-Tribromo-5-Hydroxy-1-4-Napthoquinone, A. S. Wheeler and T. M. Andrews. A Simple Density Vapor Apparatus, P. Gross. Analysis and Properties of Some Interesting Combustible Compounds, O. J. Thies. A note on the Minor Test for Dextrose and Tartrates, G. H. Satterfield.	

Northeastern Section.....	90
Chemistry in a Clothing Store, E. B. Millard. Recent Researches on Coffee, Dehydrated Foods, and Fish, E. B. Millard.	
Pittsburgh Section.....	90
A Glance at the Early Inorganic Chemistry of America, E. F. Smith.	
Puget Sound Section.....	90
Some Reactions of Nitroso Compounds, E. Z. Lynn.	
Rochester Section.....	90
St. Louis Section.....	90
A New Isomer of Phenolphthalein and Its Properties, L. McMaster and G. D. Graves.	
Southeast Texas Section.....	90
A Survey of Chemical Research in Agriculture, J. R. Neller.	
Southern California Section.....	90
Chemicals from Kelp, J. W. Turrentine.	
Deceased Members.....	90

## July.

Council.....	91
Members Elected between May 15 and June 15, 1921.....	91
Meetings of Sections:	
Chicago Section.....	92
The Electrical Theory of Oxidation, J. Stieglitz.	
Cincinnati Section.....	93
Electronic Tautomerism of Benzene Derivatives, H. S. Fry.	
Colorado Section.....	93
Delaware Section.....	93
The Technology of the American Sulfur Industry, R. F. Bacon. A Glance at the Early Organic Chemistry in the United States, E. F. Smith.	
Indiana Section.....	93
Iowa Section.....	93
Ammonium Compounds, E. C. Franklin.	
Lexington Section.....	93
Louisiana Section.....	93
The Naval Stores Industry; Its Products and Their Industrial Importance, C. F. Speh.	
Maryland Section.....	93
Personal Reminiscences of Sir William Ramsay, I. B. Remsen. The Publicity Work of the Society, J. W. Harrington.	
Minnesota Section.....	94
Some Problems in Dairy Chemistry, L. S. Palmer.	
New York Section.....	94
Committee on Industrial Alcohol of the American Chemical Society, M. H. Ittner. Industrial Alcohol and Its Relation to Prohibition Enforcement from the Manufacturers' Standpoint, M. C. Whitaker. Industrial Alcohol and Its Relation to the Pharmaceutical and Perfumery Industries, W. L. Crounse. Industrial Alcohol and Its Relation to the Flavoring Extract and Food Industries, F. M. Boyles. Legal Status of Industrial Alcohol and Its Relation to Prohibition Enforcement, A. D. Van Buren.	
Northeastern Section.....	94
The Microstructure of Wood, A. Abram. The Automotive Fuel Problem,	

D. P. Barnard. The Decolorization of Mineral Oils, L. W. Parsons. The Role of Compounding Ingredients in Rubber, C. S. Venable.	
Philadelphia Section.....	94
The Study of Organic Reactions Occurring in Living Matter, T. B. Johnson. Concerning Patents, G. K. Helbert.	
Puget Sound Section.....	94
The Chemical Phases of the Hydrometallurgy of Zinc. M. J. Falkenburg.	
Rhode Island Section.....	94
Lake Superior Iron District, W. M. Sanders.	
Rochester Section.....	94
Chemical Thermometers, J. Hudgings. Organic Phosphorus Compounds of Plants, R. F. Anderson.	
St. Louis Section.....	94
Notes on Topping Petroleum, F. W. L. Tydeman. Corrosion Prevention when Topping Petroleum, R. R. Matthews.	
Savannah Section.....	95
Scallops, J. O. Clarke. Some Phases of the Crude Drug Trade, J. J. McManus.	
South Jersey Section.....	95
Some Aspects of the Chemistry of Bacteria, W. L. Lewis.	
Southern California Section .....	95
The Lewis-Langmuir Hypothesis of Atomic Structure, H. J. Lucas.	
Toledo Section.....	95
Emulsions, H. N. Holmes. Modern Pottery, A. L. Grainger.	
University of Illinois Section.....	95
The Manufacture of Paper, R. E. Rindfusz.	
University of Michigan Section.....	95
The Boiling Points of Salt Solutions, Theoretical and Practical Considerations, W. L. Badger. Di-phenyl-beta-naphthyl-methyl, F. W. Sullivan, Jr.	
University of Missouri Section.....	95
The Influence of the Plane of Nutrition on the Maintenance Requirement of Cattle, A. G. Hogan.	
Virginia Section.....	95
The Art of Paper Making, B. K. Steadman.	
Washington, D. C., Section.....	95
Quantitative Spectrum Analysis, W. F. Meggers. Estimation of Colorless Substances by Spectro-Photometric Methods, W. E. Mathewson. A Direct Reading Spectro-Photometer for Measuring the Transmissivity of Liquids, I. G. Priest. Polarimetry, F. J. Bates. Crystal Optics in Chemistry, F. E. Wright.	
Western New York Section.....	96
Wisconsin Section.....	96
Twenty-five Years of Chemical Research on a Typically American Genus of Plants, E. Kremers. The Chemist and the Business Man, C. F. Burgess.	
Deceased Members.....	96

### August.

Council.....	97
Members Elected between June 15 and July 15, 1921.....	97
Meetings of the Sections:	
Arkansas Section.....	97

Colorado Section.....	97
Some Anode and Cathode Reactions, M. F. Coolbaugh.	
Midland Section.....	98
Magnesium Piston Alloys, J. A. Gann.	
Philadelphia Section.....	98
Industrial Alcohol and Prohibition Enforcement, Discussion.	
Pittsburgh Section.....	98
Rhode Island Section.....	98
The Chemistry of Crop Experiments, B. L. Hartwell.	
Syracuse Section.....	98
The Chemical Utilization of Wood, L. E. Wise.	
Toledo Section.....	98
Deceased Members.....	98

### September.

Council.....	99
Members Elected between July 15 and August 15, 1921.....	99
Meetings of Sections.....	99
California Section.....	99
Crystal Cleavage in Relation to Crystal Structure, A. A. Noyes. The	
Crum-Brown Substitution Rule and the Structure of Benzene, J.	
Stieglitz. Elementary Electrode Potentials, G. N. Lewis. Falsification	
in Early Chemical History, J. M. Stillman. Ammono and Mixed Aqua	
Ammono Carbonic Acid, E. C. Franklin. Studies in Protein Chemistry,	
C. Alsberg. The Crystal Structure of Potassium Cyanide, M. Bozarth.	
Crystallographic Evidence in Regard to the Structure of Benzene, M. L.	
Huggins.	
Deceased Members.....	100
Notice to Candidates intending to apply for a grant from the "Van't Hoff Fund"	
for the aid of investigators in the field of pure and applied chemistry.....	100

### October.

General Meeting Minutes.....	101
Directors' Minutes.....	103
Advisory Committee Minutes.....	104
Council Minutes.....	105
Members Elected between August 15 and September 15 1921.....	112
Meetings of the Sections:	
Colorado Section.....	113
The Present Status of the American Dye Industry, J. B. Ekeley.	
Eastern New York Section.....	113
The Physical Chemistry of Soap, J. W. McBain.	
Indiana Section.....	114
The Research at the Physical Chemistry Laboratory of the Massachusetts	
Institute of Technology, C. E. Ruby.	
Louisville Section.....	114
The Work of a Pure Science Laboratory, and Its Relation and Importance	
to Industrial Research, C. E. Ruby.	
Omaha Section.....	114
Bismuth and Its Recovery from Lead Ores, A. E. Hall.	
American Field Service Fellowships for French Universities.....	114
Deceased Members.....	114

## November.

Council.....	115
Members Elected between September 15 and October 15, 1921.....	115
Meetings of the Sections:	
Ames Section.....	115
Alabama Section.....	115
California Section.....	115
Studies in Protein Chemistry, C. L. Alsberg. The Effect of X-Rays on Certain Chemical Reactions, A. R. Olson.	
Cincinnati Section.....	116
The Work of a Pure Science Laboratory and Its Relation and Importance to Industrial Research, C. E. Ruby.	
Cleveland Section.....	116
Radium and its Production, L. F. Vogt.	
Connecticut Valley Section.....	116
Laboratory Apparatus and Appliances, T. B. Freas.	
Delaware Section.....	116
Measurement of Color as Applied to Industrial Needs, A. H. Pfund.	
Detroit Section.....	116
Dow Metal, J. A. Gann.	
Eastern New York Section.....	116
Some Investigations on the Organic Nutrition of Plants, L. Knudson.	
Indiana Section.....	116
New Chemistry for Old Chemists, G. L. Wendt.	
Lehigh Valley Section.....	116
The Laws of Evolution that Control Chemistry and Engineering, H. W. Jordan.	
Milwaukee Section.....	116
The Histology of Skin and the Chemistry of Leather Manufacture, J. A. Wilson.	
Nebraska Section.....	117
The Cosmical Function of Green Plants, H. A. Spoehr. The Nature of the Photo-Synthetic Process, Dr. Spoehr.	
New Haven Section.....	117
The Manufacture and Use of Lacquers, G. C. Givens.	
New York Section.....	117
The Microscope and How the Chemist Can Use it, E. M. Chamot.	
Northeastern Section.....	117
The Rare Earths, C. J. James. The Pending Tariff Bill, G. Jones.	
Philadelphia Section.....	117
The Absorption of Gases by Solids, H. S. Taylor.	
Puget Sound Section.....	117
Some Scientific Aspects of the Salmon Industry, R. W. Clough and C. R. Fellers.	
Rhode Island Section.....	117
Science and Civilization; The Rôle of Chemistry, C. Baskerville.	
Rochester Section.....	117
The Chemical Warfare of America, E. Hendrick.	
St. Louis Section.....	117
Metallurgy of Aluminum, R. S. Sherwin. The Mounds and Mound Builders, H. M. Whelpley.	

Toledo Section.....	117
Modern Developments in Chemical Engineering Materials of Construction, J. R. Withrow.	
University of Michigan Section.....	118
Primitive Chemical Technology, H. H. Bartlett.	
University of Missouri.....	118
A New Form of Apparatus for Separating and Purifying Radium Emanation from Radium Salts, J. E. Underwood.	
Virginia Section.....	118
Recent Work on Plasticity, E. C. Bingham.	
Washington, D. C., Section.....	118
The Constructive Chemist, E. E. Slosson.	
Wisconsin Section.....	118
A Study of Some Manganese Compounds, J. E. Day. A Recent Visit to European Chemical Laboratories, C. S. Leonard.	
Deceased.....	118

### December.

Directors' Minutes.....	119
Council.....	120
Members Elected between October 15 and November 15, 1921.....	121
Meetings of the Sections:	
Ames Section.....	121
Life Processes from the Colloidal Standpoint, R. A. Gortner.	
California Section.....	122
Science and Education, Joel H. Hildebrand. Felt Base Floor Covering, W. H. Nutting.	
Central Texas Section.....	122
Chicago Section.....	122
Some Practical Aspects of Electrometric Analysis, Paul E. Klopsteg. The Technical Magazine and Its Relation to Industry, H. C. Parmelee.	
Cincinnati Section.....	122
Engineering Aspects of the Synthetic Ammonia Process, R. S. Tour.	
Cleveland Section.....	122
Some Technical and Scientific Applications of the Colloid Chemistry of Soaps and Proteins, Martin H. Fischer.	
Colorado Section.....	122
Thermal Analysis as a Method of Discovering New Compounds, Frank E. E. Germann.	
Columbus Section.....	122
My Field of Research and What Has Been Accomplished in It, C. W. Foulk.	
Connecticut Valley Section.....	122
Vitamins, J. S. Chamberlain and L. B. Allyn.	
Delaware Section.....	122
A Modified Ionization Theory, James Kendall.	
Eastern New York Section.....	123
Early Organic Chemistry in America, Edgar F. Smith.	
Georgia Section.....	123

Deceased Members.....	128

# Proceedings.

## DIRECTORS' MINUTES.

The Directors of the American Chemical Society met at the Chemists' Club, New York City, on December 11, 1920, at 3 P.M., with Directors Noyes, Bancroft, Barnard, Bigelow, Little, Teeple and Parsons present.

In reply to a request that arrangements be made whereby members could obtain bound volumes of the journals, the Directors voted that it was in their opinion impracticable to arrange for such binding.

The Treasurer reported to the Directors that on November 9th he had borrowed, at 6%, \$12,000 and on November 24th, \$7,000 to meet the expenses of the Society, as per authority given him by the Directors, and that these loans had been paid by him on December 9th. This action of the Treasurer was officially approved.

It was voted that the safety deposit box of the American Chemical Society, No. 1641, in the Farmers' Safe Deposit Company may be entered only by the Treasurer in the presence of such member of the Finance Committee as the Treasurer may from time to time designate in writing.

It was voted to appropriate \$500 to the Annual Tables of Constants and Numerical Data.

It was voted to print a Directory during 1921, but to omit the geographical portion thereof.

It was voted that the Treasurer be authorized to spend up to \$500 from Incidental Account for furnishing a booth at the Chemical Exposition in 1921 if in his judgment it is wise to do so.

In view of a letter received from Mr. E. J. Crane, Editor of *Chemical Abstracts*, protesting against the wording of a resolution passed by the University of Illinois Section of the American Chemical Society, criticising the conduct of *Chemical Abstracts*, the Directors unanimously voted to instruct the Secretary to inform the Editor of *Chemical Abstracts* that the Directors, and in their belief the Council and most of the members of the Society, are entirely satisfied with his conduct of that *Journal* and to express their high appreciation of the efficient and competent manner in which he and his associates have handled that *Journal*, often with inadequate facilities, since he has been in charge of its affairs.

The proposed budget for 1921 was then carefully considered and was finally adopted as follows:

## INCOME (1921).

Dues.....	\$207,000.00
Subscriptions.....	20,000.00
Back Numbers.....	5,000.00
Reprints.....	1,600.00
Postage.....	3,000.00
December Index.....	1,000.00
	<hr/>
	\$237,600.00
Advertising.....	90,000.00
Interest.....	7,000.00
	<hr/>
	\$334,600.00

## EXPENSE (1921).

*Journal American Chemical Society:*

Editor.....	\$ 1,500.00	
Clerical and Office.....	1,600.00	
2900 Pages of Printing.....	47,500.00	
	<hr/>	\$50,600.00

*Chemical Abstracts:*

Editor.....	\$ 4,500.00	
Assistant Editor's Salary.....	2,750.00	
Second Assistant Editor's Salary.....	1,800.00	
Abstractors and Assistant Editors.....	9,800.00	
Clerical.....	4,500.00	
Expenses.....	1,100.00	
Formula Index.....	2,500.00	
4600 pages of Printing.....	76,800.00	
	<hr/>	\$103,750.00

*Industrial Journal:*

Editor's Salary.....	\$10,000.00	
Assistant Editor.....	3,000.00	
Clerical.....	7,400.00	
Staff Correspondents.....	4,880.00	
Office Expense.....	2,300.00	
Traveling Expense.....	1,000.00	
1200 Pages of Printing.....	47,800.00	
Rent.....	4,167.00	
	<hr/>	\$80,547.00

*News Service*

Salary.....	\$5,000.00	
Expense.....	3,790.00	
Traveling Expense.....	1,000.00	
Clerical.....	3,040.00	
Rent.....	833.00	
	<hr/>	\$13,663.00

*Advertising:*

Printing Advertisements.....	44,560.00
------------------------------	-----------

Expense.....	25.00	
		\$2,150.00
Secretary's Office:		
Salary .....	\$5,000.00	
Clerical.....	10,300.00	
Expenses.....	4,500.00	
Rent.....	1,152.00	
		\$20,952.00
Treasurer's Office		
Salary .....	\$1,000.00	
Clerical.....	1,700.00	
Expenses.....	1,000.00	
		3,700.00
President's Office:		
Traveling Expense.....	\$1,000.00	
Expense.....	200.00	
		1,200.00
Back Numbers.....	\$4,000.00	
Local Sections.....	8,500.00	
Incidentals.....	2,000.00	
General Meetings.....	2,000.00	
Directory.....	2,000.00	
Table Physical Constants.....	500.00	
		19,000.00
Total.....		\$340,122.00

CHARLES L. PARSONS, *Secretary*.

### COUNCIL.

The following communication was sent to the Council on December 1st:

AMERICAN CHEMICAL SOCIETY.

December 1, 1920.

*Council of the American Chemical Society:*

GENTLEMEN:—The following members have been duly nominated for the offices indicated for the years 1921 and 1921–1923. Kindly check your choice with an X and return the ballot on or before December 21st.

Please note that by vote of the Council the names are arranged in alphabetical order and not in the order of the nominating vote.

Very truly yours,

CHARLES L. PARSONS, *Secretary*.

*President*.—1921 only (one to be chosen) (alphabetically arranged): R. F. Bacon, E. C. Franklin, Edgar F. Smith, H. P. Talbot.

*Directors*—1921–1923, inclusive (two to be chosen) (alphabetically arranged): H. E. Barnard, A. V. H. Mory, G. D. Rosengarten, H. P. Talbot.

*Councilors-at-Large*.—1921–1923, inclusive (four to be chosen. Ballot is void unless four are voted for) (alphabetically arranged): G. P. Adamson, C. L. Alsberg, H. E. Howe, L. W. Jones, C. E. K. Mees, A. V. H. Mory, J. F. Norris, Allen Rogers.

The returns of this ballot were counted on the evening of December 21 by a committee consisting of Leo Finkelstein, L. I. Shaw and Charles L. Parsons, and the following officers were elected:

*President*, Edgar F. Smith.

*Directors*, George D. Rosengarten and H. P. Talbot.

*Councilors-at-Large*, C. L. Alsberg, H. E. Howe, L. W. Jones, Allen Rogers.

CHARLES L. PARSONS, *Secretary*.

MEMBERS ELECTED BETWEEN NOVEMBER 15 AND DECEMBER 15, 1920.

- Abramson, Samuel, 39 Schuyler St., Roxbury, Mass.  
 a Brassard, Fred, F. a Brassard & Crawford, Wakefield, Yorks, England.  
 Allen, Monica M., 602 Monroe, Ann Arbor, Mich.  
 Andrews, Andrew I., 615 N. Lake St., Madison, Wis.  
 Angel, Edward Reeve, Gresham Lodge, Streatham Common, London, S. W. 16, England.  
 Auden, Harold A., 18 Paisley St., Liverpool, England.  
 Badger, Cecil H., Hyattsville, Md.  
 Bailey, Austin, 211 Chemung St., Corning, N. Y.  
 Baker, Chester P., 53 Wendell Ave., Brockton, Mass.  
 Baker, Howard, 214 N. Lombard Ave., Oak Park, Ill.  
 Baker, Julian L., Dial Cottage, Cookham Road, Maidenhead, Berks., England.  
 Balyozian, Nicholas, 828 Blue Hill Ave., Dorchester, Mass.  
 Bartkus, Joseph, 8811 Superior Ave., Cleveland, O.  
 Basinow, Maurice, 154 Humboldt Ave., Roxbury, Mass.  
 Bawden, Arthur T., 31 Chittenden Ave., Columbus, O.  
 Beeaker, Stephen W., Phi Eta Kappa House, Orono, Me.  
 Bell, Thomas G., P. O. Box 331, Borosolvay, Cal.  
 Bernstein, Abraham J., 549 East 139th St., New York, N. Y.  
 Birchard, Frederick J., Postal Sta. B, Dominion Grain Research Lab., Winnipeg, Canada.  
 Bishop, James A., 1265 Lafayette St., Denver, Colo.  
 Blake, John T., 102 Hewlett St., Roslindale, Mass.  
 Blinn, H. M., 110 Commerce St., Baltimore, Md.  
 Blumenstiel, Monroe A., 204 Dartmouth St., Rochester, N. Y.  
 Bolan, Robert S., California Inst. of Tech., Pasadena, Cal.  
 Boulden, J. S., 5559 Pershing, St. Louis, Mo.  
 Bradley, Robert B., 58 Freeman St., Newark, N. J.  
 Brandt, Russell W., The Maury, 19th & G Sts., N. W., Washington, D. C.  
 Branham, B. T., c/o National Cannery Association, Bridgeton, N. J.  
 Braunscholtz, W. T. K., "Goslar," Adams Rd., Cambridge, England.  
 Brentnall, Blanche, 2001 East Elm, East Enid, Okla.  
 Bridges, Frank L., 36 Parker Hall, Lewiston, Me.  
 Broughall, Laurence St. C., Woodview, Hadley, Barnet, Herts, England.  
 Bunbury, Hugh M., Dudley Lodge, Prestwich, Manchester, England.

- Butler, Freeman P., 99 Salisbury St., Worcester, Mass.  
 Burns, James E., 93 Moore St., Lowell, Mass.  
 Cameron, Iain, National Tar Products, Ltd., Barrhead, Scotland.  
 Campbell, C. G., Kewaunee, Wis.  
 Carpenter, E. Keays, Box 2321, Breckenridge, Tex.  
 Child, Alfred T., Rose Polytechnic Institute, Terre Haute, Ind.  
 Cleaveland, Marion, 2196 East 87th St., Cleveland, O.  
 Coatza, S. L., 511 First Natl. Bank Bldg., San Diego, Cal.  
 Cobb, Herbert B., 83 Franklin Ave., Chelsea, Mass.  
 Comey, Paul Van A., 240 Packer, S. Bethlehem, Pa.  
 Cook, Leon W., 187 Ave. C., Bayonne, N. J.  
 Corey, Arthur B., 53 S. Winooski Ave., Burlington, Vt.  
 Corson, Ben B., 32 Walter Hastings Hall, Cambridge 38, Mass.  
 Crews, Ralph W., 228 W. Pine, Enid, Okla.  
 Croco, Carlton W., 423 N. Craig St., Pittsburgh, Pa.  
 Crosland, P. F., c/o Crosland & Pickstone Ltd., Heap Bridge, Bury, Lancashire, England.  
 Cunningham, Henry M., Bonsall & Childs Ave., Drexel Hill, Pa.  
 Cushing, Russell E., 21 Elbridge St., Worcester, Mass.  
 Cuy, Eustace, J., 307 Gilman Hall, Univ. of Cal., Berkeley, Cal.  
 Dauchy, Marguerite C., 14 Summit St., Burlington, Vt.  
 Davies, D. Owen, 4 Victoria Ave., Penarth, S. Wales, Great Britain.  
 Davis, Carl G., Onachita College, Arkadelphia, Ark.  
 Dearden, John R., Jr., 20 Charlesgate, West, Boston 17, Mass.  
 de Lacy, Sidney A., 1 Dordrecht Road, Acton, London, W. 3, England.  
 Demarest, Millard, 368 Union St., Hackensack, N. J.  
 Denker, Thomas N., 1231 East Broadway, Enid, Okla.  
 Deschamps, Andre, 5 Rue du Cure du Chateau, Tournai, Belgium.  
 Deuker, Henry W., Room 153 State House, Water & Sewage Dept., Indianapolis, Ind.  
 Diepenhorst, Edward, Tusculm College, Dept. of Chemistry, Greenville, Tenn.  
 Dingee, Harold W., 56 Pine St., New York City.  
 Dodge, Laurence E., 1001 Franklin, Normal, Ill.  
 Doidge, Russell M., c/o The Morgan Crucible Co., Ltd., Battersea, London, S. W. 11, England.  
 Donaldson, John N., 931 College St., Toronto, Ont., Canada.  
 Doyle, James E., c/o Atlas Powder Co., Webb City, Mo.  
 Dreyfus, Camille, 681 Fifth Ave., New York, N. Y.  
 Drinkard, Russell D., 1117 Third Ave., Highland Park, Richmond, Va.  
 Duche, Edgar, Usines Duche (Societe Anonyme), Vilvorde, Belgium.  
 Edington, Wallace D., 315 John Marshall Place, N. W., Washington, D. C.  
 Ehler, Harvey F., Hughes High School, Cincinnati, O.  
 Ele, Vern J., 314 Russell St., W. Lafayette, Ind.  
 Elving, Harry E., 7437 Maryland Ave., Chicago, Ill.  
 Faneuf, Leo J., 193 George St., New Brunswick, N. J.  
 Finley, A. R., R. F. D. 4, Mason City, Iowa.  
 Fowler, H. G., Associated, Cal.  
 Freeman, Benjamin, Sunset Ave., Amherst, Mass.  
 Gaddum, Leonard W., 812 Virginia Ave., Columbia, Mo.  
 Garby, Dell S., 5611 Drexel Ave., Chicago, Ill.

Gifford, Horace W. F., 90 Wolsey Ave., East Ham, London, E. 6, England.

Glass, Ellen M., 49 Parker St., Lexington, Mass.

Gleichert, Harry W., City Club, Barberton, O.

Goodavage, Joseph E., 2701 E. Westmoreland St., Philadelphia, Pa.

Grady, Giles R., 551 E. Lafayette, Jackson, Tenn.

Greeman, Omer W., 122 Pierce St., W. Lafayette, Ind.

Grimes, F. C., 512 Hobart Bldg., San Francisco, Cal.

Grunberg, George, c/o Scientific Utilities Co., Inc., 18 E. 16th St., New York, N. Y.

Hall, Walter, 944 Orville St., Kansas City, Kans.

Hayman, Sidney M. Kemiska Institutionen, Lund, Sweden.

Hemphill, R. J., Hamilton, N. Y.

Henningsen, Carleton, U. S. Forest Products Lab., Madison, Wis.

Henry, Kenneth M., c/o Illinois-Pacific Glass Co., 15th & Falsom Sts., San Francisco, Cal.

Hessler, Margaret, C., 106 E. 27th St., Austin, Tex.

Heuser, Raymond S., 929 Sheridan Road, Evanston, Ill.

Hill, S., Blundell, Spence & Co., Ltd., Beverley Road, Hull, England.

Hinkle, Carl P., 2055 Tuller St., Columbus, O.

Hinman, Walker McC. 1375 East 57th St., Chicago, Ill.

Hippensteel, Claude L., 607 University St., W. Lafayette, Ind.

Hoffman, W. F., Agricultural Biochemistry Div., Univ. Farm, St. Paul, Minn.

Holmes, Wm. M., 73-25th St., Milwaukee, Wis.

Hoops, Wm. A., 75 Chester St., Boston 34, Mass.

Hubbard, A. F., c/o E. I. du Pont de Nemours & Co., Inc., Dupont Bldg., Wilmington, Del.

Hudson, Erastus M., 261 West 73rd St., New York, N. Y.

Humphreys, Allan S., Chemistry Bldg., Fayetteville, Ark.

Hunt, Joseph O., General Delivery, Rolla, Mo.

Huntress, Ernest H., Dept. of Chem., Mass. Inst. of Tech., Cambridge, Mass.

Hurd, Sydney J., 1501 J., E. 64th St., Chicago, Ill.

Hurtado, Carlos, 28 West 83rd St., New York, N. Y.

Hutchinson, Wm. T., P. O. Box 5, Parlin, N. J.

Jacobs, M. H., Zoological Dept., Univ. of Penna, Philadelphia, Pa.

James, Harold C., Staunton Military Academy, Staunton, Va.

Jamison, Uel S., 2055 Tuller St., Columbus, O.

Jersey, Vernon, 3421 West 135th St., West Park, O.

Johnson, Donald L., 401 N. Pleasant Ave., Independence, Mo.

Johnson, Stanley J., East Eddington, Me.

Jones, Osman, Quemerford, Calne, Wilts., England.

Kay, James H., Fair Fields, Dundee Lane, Ramsbottom, England.

Keery, Edward, 431 E. 17th St., New York, N. Y.

Kehoe, Richard D., 501 Fifth Ave., New York, N. Y.

Kipp, Theodore, Jr., 1054 Grosvenor Ave., Winnipeg, Man., Canada.

Kline, Harry W., Dubois High School, Dubois, Pa.

Knowles, Etta L., 402 N. 11th St., St. Joseph, Mo.

Kooper, Landry L., Paulsen Bldg., Spokane, Wash.

Kondolf, Mathias A., 15 Lorenzo St., Rochester, N. Y.

Kramer, Benjamin, The Johns Hopkins Hospital, Baltimore, Md.

- Lacher, Aaron A., 1024 Simpson St., Bronx, New York, N. Y.  
 Langfelt, Millard, c/o Cudahy Packing Co., Omaha, Nebr.  
 Lavan, L. B., 3026 Diamond St., Philadelphia, Pa.  
 Lee, Ida Mai, 26 White Place, Bloomington, Ill.  
 Levin, Bertrem, Grosvenor Chambers, 16 Deansgate, Manchester, England.  
 Levin, Harold L., 36 Wave Way Ave., Winthrop, Mass.  
 Lewis, Harry G., 2619 West 14th St., Little Rock, Ark.  
 Lindquist, Wilbert G. A., 3 Oakdale Terrace, Jamaica Plain, Mass.  
 Linzell, H. K., 2323 Indianola Ave., Columbus, O.  
 Lummus, Walter E., 173 Milk St., Boston, Mass.  
 Lund, Ralph F., 2884 Bush St., San Francisco, Cal.  
 Lutes, Frances, 718 Lappan Rd., Ann Arbor, Mich.  
 Lynch, Lindon L., Waialua, Oahu, H. T.  
 Mackie, Gordon H., 11 Russell St., Hudson, Mass.  
 Macy, Rudolph, 103 West 127th St., New York, N. Y.  
 Matsuno, Kichimatsu, 12 Warner Rd., Hornsey, London, N. 8, England.  
 Mayo, E. W., 82 Wall St., New York, N. Y.  
 McClung, Ernest E., 830 E. 51st St., Chicago, Ill.  
 McCullough, Henry B., Boston College, University Heights, Chestnut Hill, Mass.  
 McCullough, Lloyd E., Okla. A. & M. College, Stillwater, Okla.  
 McDowell, Russell T., 166 Eastwood Ave., Providence, R. I.  
 McGavack, John, U. S. Rubber Co., Gen. Labs., New York, N. Y.  
 McKay, Neil H., 3687 Park Boulevard, San Diego, Cal.  
 McKeown, C. J. W., 29 Jackman Ave., Toronto, Ont., Canada.  
 McKillop, George F., Oil Works, Broxburn, West Lothian, Scotland.  
 Mead, Dewey M., 23rd Manlove Ave., Indianapolis, Ind.  
 Messer, Fred. C., 426 Hubbell Ave., Syracuse, N. Y.  
 Moment, Asher, 21-310 N. Illinois St., Indianapolis, Ind.  
 Moore, Charles G., 68 Grant St., Waltham, Mass.  
 Muhs, Edward J., 28 Ray St., Jamaica, N. Y.  
 Mull, Jay B., 128 Andrew Place, W. Lafayette, Ind.  
 Mullins, William E., 605 Hickory St., Texarkana, Ark.  
 Murdock, Evelyn L., 160 Aspinwall Ave., Brookline, Mass.  
 Neifert, Ira E., Knox College, Galesburg, Ill.  
 Nixon, Henry K., 421 E. University Ave., Ann Arbor, Mich.  
 Nuoffer, C. M., 900 N. Dodge St., Iowa City, Iowa.  
 Oberdoerfer, P. Benedict, Notre Dame Univ., Main Bldg., Notre Dame, Ind.  
 Oesterlein, Adolph G., c/o The Oesterlein Machine Co., Colerain Ave., Cincinnati, O.  
 Ogburn, S. Cicero, 525 Clover St., Winston-Salem, N. C.  
 Oshima, Kokichi, Kita-1, Higashi-1, Sapporo, Hokkaido, Japan.  
 Paddack, Rycken M., 4500 Fillmore St., Chicago, Ill.  
 Palmer, Truman G., 901 Union Trust Bldg., Washington, D. C.  
 Parizek, Frank J., 621 Story Bldg., Los Angeles, Cal.  
 Pesquera, Angel M., P. O. Box 758, San Juan, Porto Rico.  
 Petersen, Sverre, Roxana Petroleum Corp., Arcade Bldg., St. Louis, Mo.  
 Pigott, Madeleine G., 48 Pearl St., N. Woburn, Mass.  
 Plumb, Walter J., 222 Marsteller St., W. Lafayette, Ind.  
 Pratt, Kenneth H., 60 Eastern Ave., East Lynn, Mass.

- Price, Thomas S., c/o Institute of Chemistry, 30 Russell Square, London, W. C. 1, England.
- Purcell, James L., 31-17th St., Troy, N. Y.
- Rand, Lenox H., Sigma Phi Place, Burlington, Vt.
- Randolph A. F., E. I. du Pont de Nemours & Co., Delta Lab., Arlington, N. J.
- Reed, Frank J., 166 Devilliers St., Pittsburgh, Pa.
- Reed, Frances P., 61 Chestnut St., New Bedford, Mass.
- Remler, Raymond F., 619 N. Bever St., Wooster, O.
- Rentschler, H. C., Westinghouse Research Lab., East Pittsburgh, Pa.
- Resch, Emery C., 526 Ostrom Ave., Syracuse, N. Y.
- Richards, Margerey A., Dormitory, Yankton, S. Dak.
- Roberts, Elizabeth, Martha Cook Bldg., Ann Arbor, Mich.
- Roderick, Charles E., Columbia Hospital, San Jose, Cal.
- Rosenberg, Jacob E., 210 N. State St., Ann Arbor, Mich.
- Rosenholtz, Joseph L., 167 First St., Troy, N. Y.
- Rumsch, Hertha H., S. H. S., Staples, Minn.
- St. Georges, Henri, 157 St. Denis St., Montreal, P. Q., Canada.
- Schairer, Madalyne S., 5 Marie Ave., Bellevue Branch, Pittsburgh, Pa.
- Scharf, Elmer, 1400 N. Wells St., Chicago, Ill.
- Schmitt, G. Phil, Stricker Memorial Lab., Blackwells Island, New York, N. Y.
- Schulz, J. A., 321 E. Bowman St., Wooster, O.
- Schumacher, John W., 235 Woodland Ave., Detroit, Mich.
- Scott, James L., Twynholm, Bramley, Surrey, England.
- Seaman, Edwin H., 49 Wall St., New York, N. Y.
- Shafer, Elmer G. E., 1639 S. 54th St., Philadelphia, Pa.
- Shaw, Ralph, c/o Wailes Dove Bitumastic., Ltd., 5 St. Nicholas Blds., Newcastle-on-Tyne, England.
- Shimomura, Takeichiro, Karasumaru Kamichojamachi Kado, Kyoto, Japan.
- Smith, Albert B., Rock Cottage, Upper Clinton Ave., Ossining, N. Y.
- Smith, Hal H., 1117 Ford Bldg., Detroit, Mich.
- Spogen, Leo R., Belt, Mont.
- Stafford, James C., 151 Summac St., Wissahickon, Philadelphia, Pa.
- Standeven, Walter E., 719 Peters Trust Bldg., Omaha, Nebr.
- Steel, Charles L., Jr., 176 Holmes St., Belleville, N. J.
- Stolz, Frederick A., 328 Lux Ave., S. San Francisco, Cal.
- Storer, R. M., 537 Myrtle Ave., Kansas City, Mo.
- Sturgis, Nelson H., Jr., Dept. of Chem., Okla. A. & M. College, Stillwater, Okla.
- Sure, Barnett, Experiment Station, Univ. of Ark., Fayetteville, Ark.
- Surls, Frank L., Solvay Club House, Solvay, N. Y.
- Sutton, Willard J., 423 N. Craig St., Pittsburgh, Pa.
- Swan, William J., 170 Grafton Ave., Newark, N. J.
- Tabern, Donalee L., 207 S. Ingalls, Ann Arbor, Mich.
- Tangye, Albert W., "Thorn," Hartford, Cheshire, England.
- Taylor, Arthur W., 24½ Briggs St., Salem, Mass.
- Terrasse, Geo. L., c/o J. S. Young & Co., Hanover, Pa.
- Toubes, Benjamin, 3203 West, Ames, Iowa.
- Trimble, Harvey M., Chem. Dept., Univ. of Ark., Fayetteville, Ark.
- Valentine, C. Braxton, 110 South 3rd., Richmond, Va.

- Van der Henst, J., 1544 Tulane St., Houston, Tex.  
 Van Loan, J. W., 307 Harrison St., Syracuse, N. Y.  
 Van Zyl, Gerrit, 711 Arch St., Ann Arbor, Mich.  
 Vollrath, Alfred J., Room 661 Drexel Bldg., Philadelphia, Pa.  
 Wall, Ernest D., "Lyndthorpe," Tavistock Rd., S. Woodford, London,  
 E. 18, England.  
 Walters, John E., U. S. Gov't Expt. Station, Petrolia, Tex.  
 Wardell, Emma L., Dept. of Home Economics, Univ. of Ill., Urbana, Ill.  
 Waring, Ralph G., 2216 Cortland Ave., Syracuse, N. Y.  
 Weaver, Roy A., 156 N. Grant St., W. Lafayette, Ind.  
 Webster, Robert L., 503 Dryden Road, Ithaca, N. Y.  
 Weeks, Pearl M., 2045 Alpha Ave., S. Pasadena, Cal.  
 Weiner, Max, 224 Flatbush Ave., c/o Gelatine Products Co., Brooklyn,  
 N. Y.  
 Weiss, Charles, c/o Williamson Electric Co., 2505 Fulton St., Brooklyn,  
 N. Y.  
 Whalen, Herbert F., 85 Belmont St., Everett, Mass.  
 White, Woodford, Clemson College, S. Car.  
 Whitehead, Ralph R., Jr., 499 Beacon St., Boston, Mass.  
 Wilding, Sidney W., c/o Messrs. Claudius Ash, Sons & Co., Ltd., Angler's  
 Lane, Kentish Town, London, N. W. 5, England.  
 Wilkin, R. E., 116 E. Burlington St., Iowa City, Iowa.  
 Wilkinson, Willie H., Flush Lodge Heckmondwike, Yorkshire, England.  
 Williams, Alexander, 121 N. Union St., Rochester, N. Y.  
 Winchell, Vira F., 200 Prospect Ave., Madison, Wis.  
 Winter, A. R., Box 74, Wooster, O.  
 Wood, Benjamin F., 5539 Page Blvd., St. Louis, Mo.  
 Wood, Denys R., The County Lab., Weston Super Mare, England.  
 Wood, Edward P., P. O. Box 237, Canton, N. Car.  
 Woodhouse, Edwin D., c/o J. W. Bush Citrus Products Co., National  
 City, Cal.  
 Wright, Wm. A. S., Box 383, Princeton, N. J.  
 Wulf, Oliver R., 3562 Macomb St., N. W., Washington, D. C.  
 Zimmerli, A., Rhodia Chemical Co., New Brunswick, N. J.  
 Zirkowski, H. E., c/o American Beet Sugar Co., Oxnard, Cal.  
 Zollman, Henrietta, 5522 Kenmore Ave., Chicago, Ill.  
 Zuris, Pius J., General Pike's Hotel, Phoenixville, Pa.

#### CORPORATE MEMBERS.

- American Agricultural Chemical Co., 2 Rector St., New York, N. Y.  
 Arkell Safety Bag Co., 120 Broadway, New York, N. Y.  
 Arnold Print Works, North Adams, Mass.  
 Binalbagan Estate, Inc., 11 Broadway, New York, N. Y.  
 L. J. Bour Refractories Co., Inc., Scranton, Pa.  
 Braender Rubber & Tire Co., Rutherford, N. J.  
 W. J. Bush & Co., Inc., 100 William St., New York, N. Y.  
 Cambridge Color & Chemical Co., 29 Kent St., Somerville, Mass.  
 Chemical Catalog Co., Inc., 1 Madison Ave., New York, N. Y.  
 Coal Tar Products, Inc., 122 S. Michigan Ave., Chicago, Ill.  
 Commonwealth Chemical Corp., 15 Park Row, New York, N. Y.  
 Davison Chemical Co., 1100 Garrett Building, Baltimore, Md.  
 B. F. Drakenfeld & Co., Inc., 50 Murray St., New York, N. Y.

Drying Systems, Inc., 11 S. Desplaines St., Chicago, Ill.  
 Electro Bleaching Gas Co., 18 East 41st St., New York, N. Y.  
 Everlasting Valve Co., 2 Rector St., New York, N. Y.  
 William Garrigue & Co., Inc., 154 Nassau St., New York, N. Y.  
 General Briquetting Co., 25 Broad St., New York, N. Y.  
 Gleason-Tiebout Glass Co., 99 Commercial St., Brooklyn, N. Y.  
 Great Atlantic & Pacific Tea Co., 150 Bay St., Jersey City, N. J.  
 W. C. Hamilton & Sons, Wm. Penn P. O., Mont. Co., Pa.  
 O. Hommel Co., Box 1038, Pittsburgh, Pa.  
 Horween Leather Co., 2015 Elston Ave., Chicago, Ill.  
 Jeffrey Manufacturing Co., Columbus, O.  
 Kelly-Springfield Tire Co., Akron, O.  
 Kewaunee Manufacturing Co., Kewaunee, Wis.  
 Kimble Glass Co., Vineland, N. J.  
 Kistler, Lesh & Co., Morganton, N. Car.  
 Maurice A. Knight, East Akron, O.  
 Koppers Company, Union Arcade, Pittsburgh, Pa.  
 Krebs Pigment and Chemical Co., Newport, Del.  
 Wm. S. Merrell Co., Cincinnati, O.  
 Midland Linseed Products Co., 1253 Chamber of Commerce, Minneapolis, Minn.  
 Milwaukee Coke & Gas Co., 1112 First Wisconsin Nat'l Bank Bldg., Milwaukee, Wis.  
 Moorman Manufacturing Co., Quincy, Ill.  
 Muralo Co., New Brighton, S. I., N. Y.  
 Natural Products Refining Co., 902-910 Garfield Ave., Jersey City, N. J.  
 Newport Company, First Wisconsin Nat'l Bank Bldg., Milwaukee, Wis.  
 Noyes Bros. & Cutler, Inc., St. Paul, Minn.  
 O'Brien Varnish Co., South Bend, Ind.  
 Onyx Oil & Chemical Co., 13 Exchange Place, Jersey City, N. J.  
 Patent Cereals Company, Bradford St., Geneva, N. Y.  
 Leonard Peterson & Co., 1222-1234 Fullerton Ave., Chicago, Ill.  
 Providence Dyeing Bleaching & Calendering Co., 52 Valley St., Providence, R. I.  
 Raymond Bros. Impact Pulverizer Co., 1319 N. Branch St., Chicago, Ill.  
 Riverside Acid Works, Warren, Pa.  
 Robeson Process Co., 200 Fifth Ave., New York, N. Y.  
 Sharples Specialty Co., 23rd & Westmoreland Sts., Philadelphia, Pa.  
 Singer Manufacturing Co., Elizabethport, N. J.  
 Societe Anonyme de Produits Chimiques de Droogenbosch, Ruysbroeck-lez-Bruxelles, Belgium.  
 Sowers Manufacturing Co., Buffalo, N. Y.  
 Steere Engineering Co., Woodward & Horton Aves., Detroit, Mich.  
 Talbot Dyewood & Chemical Co., 40 Middle St., Lowell, Mass.  
 Tar Products Corporation, 913 Turks Head Bldg., Providence, R. I.  
 Arthur H. Thomas Co., West Washington Square, Philadelphia, Pa.  
 Titanium Pigment Co., Inc., Niagara Falls, N. Y.  
 Universal Oil Products Co., Room 1284-208 S. La Salle St., Chicago, Ill.  
 Western Paper Makers Chemical Co., Kalamazoo, Mich.  
 Whitall Tatum Co., Millville, N. J.  
 White Tar Co., 56 Vesey St., New York, N. Y.  
 Whitmore Manufacturing Co., Holyoke, Mass.

Will Corporation, 845 Maple St., Rochester, N. Y.  
Isaac Winkler & Bro. Co., 804 First National Bank Bldg., Cincinnati, O.

## MEETINGS OF THE SECTIONS.

[Full accounts of all meetings should be sent to Secretary Charles L. Parsons,  
1709 G St., N. W., Washington, D. C.]

### CALIFORNIA SECTION.

The 119th regular meeting of the Section was held on December 3, at the Engineers' Club, San Francisco. Papers were read as follows: "Some Improvements in Fractional Distillation," by S. W. Young of Stanford University, and "A Short History of the Chlorine Industry, by Ludwig Rosenstirn, of the Great Western Electric Chemical Co. The attendance at this meeting was 25 per cent. of the total membership.

The following officers were elected for the ensuing year:

William C. Bray, *Chairman*; Bryant S. Drake, *Vice-Chairman*; Lloyd W. Chapman, *Secretary-Treasurer*; Joel Hildebrand, Lionel H. Duschak, Ralph A. Gould, and Robert E. Swain, *Councilors*.

LOYD L. CHAPMAN, *Secretary*.

### CINCINNATI SECTION.

The 238th regular meeting of the Section, held on December 8 in the Chemistry Auditorium of the University of Cincinnati, was addressed by F. M. Callender, of Parke, Davis & Company, on "Standardization of Drugs."

C. H. LUND, *Secretary*.

### CLEVELAND SECTION.

At the meeting on November 5, the following officers for 1921 were elected: L. C. Drefahl, *Chairman*; W. R. Veazey, *Vice-Chairman*; H. S. Booth, *Secretary-Treasurer*; H. D. Batchelor, W. M. Clark, H. Gruener, B. C. Goss, W. R. Mott, N. K. Chaney, *Board of Managers*; R. D. Landrum, A. W. Smith, Hugo Schapiro, and H. E. Simmons, *Councilors*.

WM. ROY MOTT, *Secretary*.

### COLORADO SECTION.

S. C. Lind, of the U. S. Bureau of Mines, Golden, Colo., read a paper on "The Disruption of the Atoms and the Possibility of Transmutation of the Elements," before the Section, November 22.

The Section held a banquet on Wednesday evening, December 15, at the Hotel Metropole, Denver, Colo.

RUTH B. VORTREES, *Secretary*.

### CONNECTICUT VALLEY SECTION.

On December 11, Harold Hibbert, of Yale University, spoke before the Section on "The Constitution of Cellulose."

HARRY WESSELS, *Secretary*.

### CORNELL SECTION.

At the regular meeting, held on December 1, W. W. Rowlee addressed the Section on "Chemical Botanical Problems."

On December, 15, Sutherland Simpson spoke before the Section on "Chemical Control in the Body."

F. R. GEORGIA, *Secretary.*

#### DELAWARE SECTION.

On December 22, Joseph S. Ames, professor of physics, Johns Hopkins University, spoke before the Section on "Relativity."

FRED C. ZHISBERG, *Secretary.*

#### EASTERN NEW YORK SECTION.

On December 17, James Kendall, of Columbia University, addressed the Section on the subject, "A Modified Ionization Theory."

MARY R. ANDREWS, *Secretary.*

#### GEORGIA SECTION.

J. L. McGhee, of Emory University, addressed a called meeting of the Section, November 19, on the subject, "Osmotic Pressure."

J. S. BROGDON, *Secretary.*

#### INDIANA SECTION.

At the regular meeting of the Section, held on December 10, the following addresses were given: "Some Problems of the Canning Industry," by John P. Street, director of Indiana Inspection Service, National Canners Association; and "Some Things a Chemist Should Know about Patents," by George G. Schley, *Patent Attorney.* Attendance, 31%.

EDGAR B. CARTER, *Secretary.*

#### LEHIGH VALLEY SECTION.

The following program was given before the Section at its meeting held at Palmerton, Pa., on December 4: "New Instruments for Paint Testing," by A. H. Pfund, of Johns Hopkins University; "Industrial Microscopy," by H. Green, and "Research Progress," by F. G. Breyer, of the Research Division, New Jersey Zinc Co. Attendance 33-47%.

JOHN T. LITTLE, *Secretary.*

#### LEXINGTON SECTION.

The 65th meeting of the Section was held at the University of Kentucky on November 23, when C. S. Crouse, of the University, spoke on "Oil Shales of Kentucky."

The 66th meeting was held on December 15 at the University of Kentucky. A paper entitled, "A Rapid Method for the Analysis of Dolomite and Magnesian Limestones," was presented by S. D. Averitt. A report on the annual convention of the Association of Official Agricultural Chemists was made by R. H. Ridgell. Attendance, 45%.

O. M. SHEDD, *Secretary.*

#### LOUISIANA SECTION.

The regular monthly meeting of the Section was held on November 16, at which time Dr. Wm. A. Noyes, President of the American Chemical Society, spoke on "The Foundations for Chemical Development."

CASSIUS L. CLAY, *Secretary.*

## MARYLAND SECTION.

The 45th regular meeting of the Section occurred on December 1, in the Chemical Laboratory Lecture Room of Johns Hopkins University. Davis I. Macht, of the Johns Hopkins Medical School, spoke on the "Relation of the Chemical Structure of the Opium Alkaloids to their Physiological Action." Dr. Macht also touched on the "Synthetic Substitutes of the Opium Alkaloids." 25% of the membership was in attendance.

C. CLIFTON HOWES, *Secretary*.

## MICHIGAN AGRICULTURAL COLLEGE SECTION.

The meeting of the Section on December 11 was held at the Hotel Kerns, Lansing, Mich., when William McPherson, head of the Department of Chemistry and dean of the Graduate School in Ohio State University, spoke to the members. Attendance, 93%.

BRUCE E. HARTSUCH, *Secretary*.

## MILWAUKEE SECTION.

The Chicago and Milwaukee Sections engaged in an indoor baseball game at the Milwaukee Athletic Club on November 20, at 4.45 P.M. Following the banquet in honor of the visiting guests, short talks on industrial subjects were given by members of both Sections.

On December 3, J. D. Mathews, of the University of Wisconsin, spoke before the meeting of the Section, his subject being, "Photo-Chemistry."

WM. KLOPPENBURG, *Secretary*.

## NASHVILLE SECTION.

Wm. D. Harkins, professor of Physical Chemistry in the University of Chicago, addressed the meeting of the Section, which occurred on November 18, on the subject, "Atoms and How They are Built."

H. A. WEBB, *Secretary*.

## NEBRASKA SECTION.

On December 14, Ernest Anderson, for three years in the Transvaal University College of South Africa, spoke before the Section on "Some Chemical Problems Peculiar to South Africa."

B. CLIFFORD HENDRICH, *Secretary*.

## NEW HAVEN SECTION.

At the regular meeting of the Section, held on December 14, C. R. Hoover, of Wesleyan University, spoke on "The Detection of Small Amounts of Carbon Monoxide."

BLAIR SAXTON, *Secretary*.

## NEW YORK SECTION.

At the meeting of the Section held on December 10, Hugo S. Taylor spoke on the subject, "The Mechanism of Catalytic Processes."

HERBERT G. SIDEBOTTOM, *Secretary*.

## NORTHEASTERN SECTION.

The 162nd regular meeting of the Section occurred on December 10, at the Engineers' Club, Boston, Mass., when W. T. Bovie, assistant

professor of biophysics at the Medical School of Harvard University, spoke on "The Structure of Protoplasm in the Light of the Electron Theory of Matter."

L. F. HAMILTON, *Secretary*.

#### OKLAHOMA SECTION.

The second annual meeting of the Section was held on November 19 and 20, at Stillwater, Okla. The following program was carried out: November 19.—"The Foundations for Chemical Development," by Wm. A. Noyes, president of the American Chemical Society. November 20.—Presidential address, by Edwin Debarr; "The Production of Cylinder Stocks from Oklahoma Crudes," by Sidney Born; "The Nitrogen Distribution of the Alkali-Soluble Proteins of Cottonseed Meal," by W. G. Friedmann; "Milk," by Edwin Debarr; "The Preparation of Glycollic Acid," by Hilton Ira Jones; and "Positive and Negative Valence," by W. A. Noyes. The business meeting and annual election of officers occurred at the close of the program.

HILTON IRA JONES, *Secretary*.

#### PHILADELPHIA SECTION.

At the regular monthly meeting of the Section, held on December 16, the following program was presented: "The Receptivity of Dyes to Proteins," by George Heyl, of Heyl Laboratories, New York City; and "Arsphenamin," by George W. Raiziss, of the Philadelphia Dermatological Institute.

J. HOWARD GRAHAM, *Secretary*.

#### PUGET SOUND SECTION.

At the meeting of the Section held on December 9, F. R. Heath, of the Chemistry Department, University of Washington, addressed the members on "Phosphorescent Substances." The annual election of officers occurred at this meeting.

ROBT. T. ELLIOTT, *Secretary*.

#### ROCHESTER SECTION.

The 113th regular meeting of the Section, on November 23, was addressed by Richard B. Moore, chief chemist of the U. S. Bureau of Mines, on the subject, "Helium, Its History, Preparation and Uses." The members of the Science Section of the New York State Teachers Association were guests at this meeting. Membership attendance was 66-2/3 per cent.

On December 6, a joint meeting between the Local Section and the Optical Society of America, Rochester Section, was held at the University of Rochester. L. A. Jones, of the Eastman Kodak Company, gave an illustrated lecture on "Measurement and Specification of Color."

ERLE M. BILLINGS, *Secretary*.

#### SAVANNAH SECTION.

The Section began its active fall and winter work with a meeting on November 22, when H. S. Bailey gave a review of the Council meeting and session of the Society at Chicago. R. F. Monsalvatge covered the entertainments and industrial trips provided for the visiting chemists

at Chicago. This was followed by a report on the Chemical Industries Exposition in New York, by V. H. Bassett. Attendance, 40 per cent.

#### ST. LOUIS SECTION.

R. D. Oilar, of the Brecht Company, gave an illustrated lecture on December 6, before the Section, taking as his subject "Vegetable Oil Industries."

T. R. BALL, *Secretary*,

#### SOUTHEAST TEXAS SECTION.

At the 15th meeting of the Section, held on December 11, R. G. Upton, City Sanitary Engineer of Port Arthur, addressed the members on the subject, "The Work of a City Chemist."

P. S. TILSON, *Secretary*.

#### SOUTH JERSEY SECTION.

On December 8, Allen Rogers, of Pratt Institute, spoke before the fifth regular meeting of the Section on the subject, "Shark Fishing and Shark Leather."

C. E. BURKE, *Secretary*.

#### SYRACUSE SECTION.

The 144th regular meeting of the Section occurred on November 19. Thomas W. Pritchard, of Columbia University, spoke on "The Whitaker-Pritchard Process of Destructive Distillation."

The 145th regular meeting, held on December 17, was addressed by Ellwood Hendrick, of New York, on "Relativity and Life." Attendance, 25%.

B. W. GRIMES, *Secretary*.

#### TOLEDO SECTION.

The regular monthly meeting of the Section was held on December 13. Oliver Kamm, director of the Chemical Research Department of Parke, Davis & Co., Detroit, Mich., gave a paper on "Organic versus Inorganic Analysis." Announcement is made of the publication of the first directory of the Section.

R. W. ERWIN, *Secretary*.

#### UNIVERSITY OF ILLINOIS SECTION.

At the regular meeting of the Section on November 16, the following officers for the year 1921 were elected: Roger Adams, *Chairman*; L. H. Smith, *Vice-Chairman*; S. A. Braley, *Secretary*; J. H. Reedy, *Treasurer*; G. D. Beal and E. W. Washburn, *Councilors*. A paper on "Energy from the Bacteriologist's Viewpoint," was presented by F. W. Tanner.

S. A. BRALEY, *Secretary*.

#### UNIVERSITY OF MICHIGAN SECTION.

F. E. Bartell gave a paper on "Anomalous Osmose and its Relation to the Behavior of Certain Colloid Systems," before the regular meeting of the Section, held on November 30.

R. J. CARNEY, *Secretary*.

#### UNIVERSITY OF MISSOURI SECTION.

The 95th meeting of the Section was held on December 3, when H. E. Patton, of St. Louis, gave an address on "Reality as a Factor in Research." Attendance, 100 per cent.

H. D. HOOKER, JR., *Secretary*.

## VIRGINIA SECTION.

The 37th meeting of the Section, on November 19, had as its speaker, Graham Edgar, professor of chemistry at the University of Virginia, whose subject was, "Architecture of the Atom." Attendance, 50 per cent.

The 38th meeting of the Section was held on December 17. A lecture illustrated by lantern slides, on the subject, "The Physics of Flying," was delivered by Robert E. Loving, professor of Physics at Richmond University.

ROBERT F. McCracken, *Secretary*.

## WASHINGTON, D. C., SECTION.

On November 11, the following officers of the Section were elected: William Blum, *President*; J. B. Reed, *Secretary*; F. P. Dewey, *Treasurer*; W. M. Clark, W. D. Collins, A. Seidell, F. W. Smither, and R. B. Sosman, *Councilors*.

The 312th meeting was held on December 9, when the following program was given: "Petroleum Products," by J. P. Lewis; "Coal Tar Products," by W. M. Rile; "Industrial Alcohol," by B. R. Tunison; and "Forest Products," by E. C. Sherrard.

J. B. REED, *Secretary*.

## WISCONSIN SECTION.

At a special meeting of the Section, held on November 23, Frederick G. Cottrell, director of the U. S. Bureau of Mines, spoke on "Commercial Liquefaction and Separation of Gases."

On December 15, Arthur I. Kendall, dean of the Medical School, Northwestern University, spoke before the Section on "Bacteria as Chemical Reagents."

JOHN H. SCHMIDT, *Secretary*.

## DECEASED.

Drew, Dr. Charles W., 322 Fourth St., South Minneapolis, Minn. Died, November 25, 1920.

Dreyfus, Louis A., Maple Ave., Rosebank, S. I., N. Y. Died, December, 1920.

Eberly, H. W., Atlas Powder Co., Lansing, N. J. Died, Oct. 16, 1920.

Farnsworth, J. P., 52 Valley St., Providence, R. I. Died, Dec. 3, 1919.

Massey, J. R., Glass Founders Corp., Milftown, N. J. Died, Nov. 19, 1920.

Rowley, Walter E., 21 Burling Slip, New York City. Died Oct. 9, 1920.

Surface, Henry Earl, Valuation Engineer in Forest Industries, Washington, D. C. Died, June 9, 1920.

# Proceedings.

## Report of the Secretary of the American Chemical Society for the Year 1920.

The growth of the American Chemical Society during the year 1920 has again been large. The society has made a net gain of 1,896 members during the year. The membership of the Society at the end of 1919 was 13,686. It was 15,582 on December 31, 1920. Statistics follow:

Honorary members.....	9
Life members.....	21
Corporation members.....	99
Members.....	15,453

Total, Dec. 31, 1920..... 15,582

During the year one honorary member, Dr. Ernest Solvay, was added.

The number of members now in arrears registered in the Local Sections on November 30, 1919, was 10,306; the number on November 30, 1920, was 11,623. The number in each Section for 1919 and 1920 is noted below:

Local section.	Number of paid mem- bers, 1919.	Number of paid mem- bers, 1920.	Cash retained from balance, 1919.	Total Dr. account 1920.
Alabama.....	54	63	\$47.89	\$67.50
Ames.....	32	36	.06	50.06
California.....	333	370	...	200.00
Central Texas.....	57	60	...	50.00
Chicago.....	694	892	...	520.50
Cincinnati.....	230	248	83.06	200.00
Cleveland.....	376	411	31.14	282.00
Colorado.....	...	111	...	22.98
Columbus.....	96	101	...	100.00
Connecticut Valley.....	101	114	...	100.00
Cornell.....	45	51	0.16	50.16
Delaware.....	363	258	0.38	200.38
Detroit.....	129	148	...	155.00
Eastern New York.....	82	98	83.98	83.98
Georgia.....	73	50	...	25.00
Indiana.....	181	208	...	181.00
Iowa.....	67	77	31.23	81.23
Kansas City.....	158	195	71.40	158.00
Lehigh Valley.....	136	123	...	136.00
Lexington.....	26	27	...	50.00
Louisiana.....	56	73	1.46	70.00
Louisville.....	25	30	...	...
Maine.....	57	55	...	25.00
Maryland.....	201	231	27.22	150.75

Social section.	Number of paid mem- bers, 1919.	Number of paid mem- bers, 1920.	Cash retained from balance, 1919.	Total Dr. account, 1920.
Michigan Agricultural College...	28	30	...	50.00

Southern California.....	179	242	9.02	179.00
Syracuse.....	173	143	11.04	173.00
Toledo.....	52	68	1.73	73.50
University of Illinois.....	127	139	61.54	155.00
University of Michigan.....	54	62	12.12	37.12
University of Missouri.....	19	26	28.21	28.21
Vermont.....	19	24	42.12	42.12
Virginia.....	90	107	23.96	112.50
Washington, D. C.....	383	379	90.35	287.25
Western New York.....	273	305	...	204.75
Wisconsin.....	116	138	10.42	110.42
	10,306	11,623	\$1,130.42	\$8,801.97

The table gives a summary of the sectional accounts for the year, shows the number of members in each Section for 1919 and 1920, the funds held over from 1919 account, and the total funds (which include the balances) charged to the 1920 account.

During the year the Society added the Colorado, Omaha, Savannah and South Jersey Sections to its Local Sections.

During the past two fiscal years, December 1, 1918, to November 30, 1920, the Secretary has made collections as follows:

	1919.	1920.
Membership dues or subscription.....	\$125,428.00	\$140,482.00
Subscriptions .....	13,208.72	15,863.98
Back numbers.....	5,765.54	9,127.02
Reprints.....	1,305.31	1,626.81
Postage.....	2,878.65	3,719.05
Interest.....	802.63	659.87
Exchange and miscellaneous.....	137.78	26.41
Directory.....	140.75	18.00
Decennial Index to Chemical Abstracts.....	1,898.25	1,699.00

\$151,565.63    \$173,222.14

These amounts were duly transmitted to the Treasurer of the Society.

Subscriptions and the sale of back numbers during the past year have again increased.

Several complete sets of our journals have been sold to foreign and domestic libraries and several incomplete sets have been added to by the purchase of odd volumes where they could not be furnished from the stock. The stock has been kept in good condition by the purchase of numbers needed to complete full volumes, but sets are now hard to obtain, as many volumes are already sold out or are nearing exhaustion.

Back numbers are mailed direct from Easton, Pa., on orders sent through the Secretary's office. The following is a summary of the back numbers sent out by the Secretary during the year, together with the present stock of journals:

Copies of the Society's publications sent out from January 1, 1920, to December 31, 1920, aside from mailing lists.....	64,958
Copies of the Jour. Amer. Chem. Soc. in stock.....	18,840
Copies of Chemical Abstracts in stock.....	17,498
Copies of the Jour. Ind. & Eng. Chem. in stock.....	17,626
Copies of the General Index, Vols. 1-20, J. A. C. S. in stock.....	75
Copies of Anniversary Number in stock.....	92
Volumes of Decennial Index in Stock.....	381

The Society has grown in influence in even more rapid degree. It has been very influential in passing important chemical legislation which is beneficial not only to the Society but to the country at large. The American Chemical Society News Service is being received regularly by several hundred publications throughout the country and its bulletins are widely reprinted. The average salaries of chemists have increased during the last few years probably to a greater extent than any other profession. There is no technical profession in the world where the members are so united and where they work so as a unit for the development of their science as do the chemists of America. There has never been a time in the history of the world when chemists and the chemical profession were appreciated by the public as they are to-day. Two successful general meetings were held during the year, one at St. Louis and one at Chicago,

and both had an inspiring effect upon the chemical life and chemical thought of their communities. The Dye Chemistry Section has become a large, enthusiastic and active Dye Chemistry Division. Sections of Sugar Chemistry, Cellulose Chemistry and Leather Chemistry have been formed and are rapidly proving their worth and the probable future need of divisions in these special lines of endeavor. The Colorado, Omaha, Savannah, and South Jersey Sections have been added to our Local Sections during the year. The Board of Editors of Scientific and Technological Monographs have begun active work and important books bearing the emblem and the backing of the American Chemical Society will shortly be issued as the first of a series of American Chemical Society Chemical Monographs. The first, "The Chemistry of Enzyme Action," is now in press. Our journals are increasing daily in importance and recognition throughout the world. The *Journal of Industrial and Engineering Chemistry* is being recognized more and more as the most valuable advertising medium in the world to reach chemists and the chemical industries, and its advertising has grown so large and so important that it has now been turned over to a competent, hustling firm to handle. Plans are already under way for an important general meeting in Rochester, April 26 to 29, 1921, and for a world-wide gathering of chemists in New York in the early days of September, when the British Society of Chemical Industry will come down from its general meeting in Canada to meet with its New York Section, with the American Chemical Society, with the Seventh National Exposition of Chemical Industry, and with other bodies of chemists that may desire to meet in New York City at that time. The year 1921 promises to be a banner year for the American Chemists and American Chemical Industry.

The Secretary wishes to express his appreciation for the continued assistance and loyal support of members of the Society. Without their aid little could be accomplished. Respectfully submitted,

CHARLES L. PARSONS, *Secretary*.

### Report of the Editor of the Journal of the American Chemical Society for the Year 1920.

The number of papers and book reviews and the number of pages devoted to them in the JOURNAL during the past five years have been as follows:

	Number.					Pages.				
	1916.	1917.	1918.	1919.	1920.	1916.	1917.	1918.	1919.	1920.
Proceedings.....	...	...	...	...	...	109	173	112	162	168
Physical and Inorganic.	161	136	114	107	180	1618	1243	1023	1053	1695
Organic and Biological..	146	164	106	116	122	1265	1482	906	1089	936
Book Reviews.....	41	37	21	29	54	41	30	30	31	59
Total.....						2933	2928	2071	2335	2858

There has evidently been a marked increase in the size of the JOURNAL as compared with last year. Indeed, the pre-war figures were almost attained, so that the prediction made in the last Report has been emphatically fulfilled. This increase occurred in spite of still greater insistence on conciseness and brevity of presentation. This insistence did, however, have the effect of reducing the average length of the articles from 9.1 in 1916 and 17; 9.5 in 1918, and 9.6 in 1919, to 8.7 pages during the past year. On the basis of these figures and the present influx of new manuscripts, it is probable that a still further increase will occur during the coming year, unless further restrictive measures are adopted.

During the past year the resignation of Dr. Marston T. Bogert from the Editorial Board was reluctantly accepted. Dr. Bogert has served the Society faithfully, wisely, and unselfishly as Associate Editor for many years. The Editor wishes to express appreciation and gratitude on his own behalf and on that of the Society for this service. The Editor also wishes to report the election during the past year of Dr. Lauder W. Jones and Dr. James F. Norris as Associate Editors.

ARTHUR B. LAMB, *Editor*.

### Report of the Editor of Chemical Abstracts for the Year 1920.

The 1920 volume of *Chemical Abstracts* contains 18,051 abstracts, an increase of 3,353 over the preceding volume. These cover 3,826 pages. The edition has been 15,000 copies per number throughout most of the year. Of the abstracts 13,619 are of journal and like papers and 4,432 of patents. The abstracts of patents have averaged 0.105 page in length and the others 0.223 page, as against 0.115 and 0.244, respectively, in 1919. The reduction in length of abstracts was brought about during the second half of the year owing to budget restrictions. Advances in paper and printing costs, while the amount of literature to be abstracted was increasing rather rapidly, made retrenchment necessary. For this same reason the table of contents and the author indexes to the individual numbers were omitted during the second half of the year. It seemed better to omit something of temporary value only than to hold out abstracts or reduce them further.

By the death, on January 19th, 1919, of Mr. A. Hugh Bryan, who had been Assistant Editor in charge of the section on Sugar, Starch and Gums for almost nine years, we lost a good and faithful worker. His interest in *Chemical Abstracts* never lagged during his long service on the journal.

During the year the plan of the first formula index to *Chemical Abstracts* has been worked out and the compilation has been in progress. Such an index is not easy to prepare. The inclusion of this formula index had added several weeks to the time required to issue the Index Number, but it is believed that its usefulness will make up many times for the

expense and wait involved. A discussion of this index will be found in a foreword at its beginning.

The book title service of *Chemical Abstracts* has been improved. The number of titles published during the year is 1,275. References to published reviews are now given whenever possible.

A coöperative arrangement was made with Mr. Homer F. Staley, Editor of the *Journal of the American Ceramic Society*, during the latter part of the year for the obtaining of abstracts of papers in which both this JOURNAL and *Chemical Abstracts* are interested. The coöperative arrangement with the editors of the *Journal of the Chemical Society (London)* and the *Journal of the Society of Chemical Industry*, entered into in 1919, has worked out very satisfactorily.

A questionnaire sent out last September covering several points in connection with *Chemical Abstracts* contained a request for opinions as to whether five years or ten years would be considered the most suitable period to be covered by the next collective index to the journal. The vote received was 113 for a ten-year and 30 for a five-year index. The opinion seemed to be that a longer span of years per collective index and fewer such indexes would be more satisfactory in the long run in view of the probable usefulness of *Chemical Abstracts* over a long period of years.

At the beginning of 1920 the title of Section 16 was changed from "Fermented and Distilled Liquors" to "The Fermentation Industries." Dr. H. S. Paine assumed charge of this section at that time.

Other new assistant editors are Dr. R. S. Williams, in charge of Metallography, and Dr. F. W. Zerban, in charge of Sugar, Starch and Gums. The value of the journal of the spirit of service shown continually by the assistant editors and abstractors is very great. The editor wishes again to express his appreciation of this spirit and to state his belief that the members of the Society appreciate it.

Statistics for the various sections follow:

	No. pages.	No. abstracts.
Apparatus.....	37.7	250
General and Physical Chemistry.....	243.6	1169
Subatomic Phenomena and Radiochemistry.....	137.1	655

3826.0

Respectfully submitted,

E. J. CRANE.

### Report of the Editor of the Journal of Industrial and Engineering Chemistry.

Two prominent features stand out in connection with the *Journal of Industrial and Engineering Chemistry* for the year 1920:

1. As the result of a direct appeal to contributors and of the thorough work of the reviewers in recommending condensations of articles, it has been possible to proceed rapidly with the publication of a large number of articles, thereby enabling at the present time prompt publication of original papers, as far as this is consistent with their thorough review. It is a pleasure here to make grateful acknowledgment of the helpful coöperation of every member of the Society who has been requested to aid in this important work of review of papers.

Throughout the past year we have had the good fortune to have the work of editing papers entirely in charge of Miss Ruth Thomas, formerly of the Research Staff of the Massachusetts Institute of Technology. The painstaking and thorough work of Miss Thomas in preparing the manuscripts for the printer has resulted in a distinct improvement in many papers published during the year. Her valuable work is attested by many of our contributors.

2. On the authorization of the Directors, a complete change in the management of the Advertising Department has been made. This entire matter has been turned over to the Chemical Catalog Company, Inc., on a commission basis, the Society reserving, however, the right of rejection of any advertisement and continuing to develop in consultation with the Chemical Catalog Company the advertising policies of the Journal. The effective work of the new Advertising Department, begun as it was under rather complicated conditions and in the face of a fifty per cent. increase in advertising rates, justifies the hope that during the coming year this feature of the work will be thoroughly taken care of.

On account of the very large increase in rental demanded by the new owners of the former quarters of the Journal, a change of location was made necessary, and it was extremely fortunate that the present admirable rooms could be found in the tower of the Metropolitan Building, where the Advertising Department was already located.

During the year two important new features were added to the Journal, namely, monthly letters from distinguished correspondents in London and Paris. It is hoped to continue to expand this foreign news feature by the inclusion from time to time of occasional letters from other European chemical centers.

As a result of the action of the Directors at the last annual meeting, we have been able to add to our staff in part-time capacity Dr. Robert P. Fischelis, whose experience and interest in publication matters will prove a valuable asset in the work during the coming year.

The A. C. S. New Service continues to grow in usefulness. More and more it is finding a definite and acceptable place in the newspaper offices of the country and under the increased appropriation recently granted, it is proposed to extend this work as far as possible into the field of the weekly newspapers, thereby increasing more and more the public understanding of the significance of chemistry to the nation.

Much time has been required to get the monthly Clip Sheet issued by the News Service thoroughly established. The first attempts to include in this Clip Sheet textually reproduced sections of the Journal did not yield very great success. This was then modified in form to cover popular treatment of articles appearing each month in the Journal, and the clippings being received show that this feature is now on a thorough basis and is being widely made use of by the press.

For comparison with the previous year, there follows a statistical résumé of the contents of the Journal for 1919 and 1920:

	Number of pages.	
	1919.	1920.
Title and Contents.....	12.0	12.0
Editorials.....	37.7	29.0
Chemical Warfare Service.....	166.5	24.9
Other War Activities.....	12.4	....
Original Papers.....	311.1	582.0
Laboratory and Plant.....	81.2	131.2
Features.....	133.6	122.0
Addresses and Contributed Articles.....	82.6	54.8
Symposia.....	39.1	...
Medal Awards.....	7.5	29.7
Works and Laboratory accidents.....	5.4	...
Foreign Industrial News.....	28.7	5.1
Scientific Societies.....	57.5	47.4
Obituaries.....	1.5	2.6
Bibliographies.....	17.2	...
Notes and Correspondence.....	42.9	35.0
Washington Letters.....	18.0	14.1
London Letters.....	...	2.0
Paris Letters.....	...	3.0
Industrial Notes.....	30.0	16.2
Personal Notes.....	22.6	17.4
Government Publications.....	45.1	48.7
Book Reviews.....	15.1	16.9
New Publications.....	12.3	12.0
Market Report.....	12.0	23.0
Index.....	20.0	18.0

Total Editorial Pages..... 1,212.0      1,247.0

Total Advertising Pages..... 1,300      1,312

Total Number of Copies Issued..... 172,600      198,300

Respectfully submitted,

CHAS. H. HERTY, *Editor*.

## COUNCIL.

MEMBERS ELECTED BETWEEN DECEMBER 15, 1920, AND JANUARY 15, 1921.

Adams, C. Calvin, L. H. Gilmer Co., Keystone and Vincent Sts., Tacony, Philadelphia, Pa.

Adan, Robert, 4 Korte Meir, Ghent, Belgium.

Ahlbeck, Harry W., 2229 Harrison St., Evanston, Ill.

Anderegg, L. T., Box 37, Station A., Ames, Iowa.

Anderson, Paul J., 18 Ridge St., S. Manchester, Conn.

Andrews, Fred. R., 1210 Joseph St., New Orleans, La.

Arentz, Fred B., c/o U. S. Industrial Alcohol Co., Res. Lab., S. Baltimore, Md.

Bailey, Douglas P., 1409 E. 2nd St., Austin, Tex.

Baird, Kenneth E., Donner Union Coke Corp., Buffalo, N. Y.

Baird, W. H., Northern Sugar Corp., Mason City, Ia.

Balch, Royal T., 332 Seaton Place, N. E., Washington, D. C.

- Bardwell, Dwight C., 2141 Berkeley Way, Berkeley, Cal.  
 Barker, Wm. F., 143 Duke St., Southport, England.  
 Bass, L. W., 1248 Yale Station, New Haven, Conn.  
 Beckman, Arnold O., 412 E. Green St., Champaign, Ill.  
 Beisel, Harold D., 5067 Spalding Ave., St. Louis, Mo.  
 Benedict, A. J., 328 Seneca Parkway, Rochester, N. Y.  
 Beneke, Walter, 3734 Utah Place, St. Louis, Mo.  
 Bennett, Albert L., 409 Tabor Opera House Bldg., Denver, Colo.  
 Bick, Jacob A., 1076 Roosevelt Road, W., Chicago, Ill.  
 Bishop, Oakley M., 910 Blackshire Road, Wilmington, Del.  
 Bitterman, Grace V., 1717 Chadbourne Ave., Madison, Wis.  
 Blair, J. S., 3409 34th Place, N. W., Washington, D. C.  
 Blakey, Walter, 569 London Road, Oakhill, Stoke-on-Trent, England.

### MEETINGS OF THE SECTIONS.

[Full accounts of all meetings should be sent to Secretary Charles L. Parsons,  
 1709 G St., N. W., Washington, D. C.]

#### CHICAGO SECTION.

A joint meeting of the Chicago Section of the American Chemical Society and the American Association for the Advancement of Science was held in Chicago on December 29. Two addresses were made, as follows: "Some Present Aspects of Chemistry in the United States," by B. F. Lovelace, of Johns Hopkins University; and "Experimental Tests of the Radiation Hypothesis," by Farrington Daniels, of the University of Wisconsin.

S. L. REDMAN, *Secretary*.

#### CLEVELAND SECTION.

On December 21, H. N. Holmes, of Oberlin College, addressed the Section on "Applications of Colloidal Chemistry." Attendance, 30%.

H. S. BOOTH, *Secretary*.

## DETROIT SECTION.

The 121st meeting of the Section occurred on December 15, the address of the evening being given by A. F. MacFarland, of the Vanadium-Alloy Steel Co., who spoke on "The Relation Between Chemical Analyses and the Quality of Tool Steels."

WM. B. TEMPLETON, *Secretary*.

## INDIANA SECTION.

At the regular meeting of the Section, held on January 14, the following program was given: "Activated Nitrogen, Hydrogen, and Oxygen," by F. O. Anderegg, of Purdue University; and "A Movement to Establish the Coöperative Relation Between Science and the Industries in Indiana," by I. H. Derby, of the Republic Creosoting Company.

EDGAR B. CARTER, *Secretary*.

## KANSAS CITY SECTION.

The 147th meeting of the Kansas City Section was held on December 11. Two addresses were given, as follows: "History of the Kansas City Section," by F. B. Dains; and "Chemical Control of Bread-Making," by C. J. Patterson. The following officers were elected for 1921: H. C. Allen, *Chairman*; W. B. Smith, *Vice-Chairman*; Lee Clark, *Secretary-Treasurer*; H. M. Elsey, *Assistant Secretary*; F. B. Dains and Rudolph Hirsch, *Councilors*. Attendance, 23%.

W. B. SMITH, *Secretary*.

## LEHIGH VALLEY SECTION.

The following officers have been elected by the Section for the year 1921: Henry J. Wysor, *Chairman*, and Judson G. Smull, *Secretary-Treasurer*.

JUDSON G. SMULL, *Secretary*.

## LOUISVILLE SECTION.

The first fall meeting of the Section was held on November 5, when the following officers were elected for 1921: G. A. Goodell, *Chairman*; C. E. Geiger, Jr., *Secretary*; and Alfred W. Homberger, *Councilor*.

C. E. GEIGER, JR., *Secretary*.

## MICHIGAN AGRICULTURAL COLLEGE SECTION.

The following officers were elected by the Section for the year 1921: R. C. Huston, *Chairman*; D. L. Dandall, *Vice-Chairman*; C. S. Robinson, *Secretary*; O. B. Winter, *Treasurer*; and A. J. Patten, *Councilor*.

C. S. ROBINSON, *Secretary*.

## MIDLAND SECTION.

At a meeting of the Section, held on December 8, Thomas Griswold, Jr., presented a paper entitled, "Reminiscences." Attendance, 66 $\frac{2}{3}$ %.

C. C. KENNEDY, *Secretary*.

## MILWAUKEE SECTION.

On September 3, Arthur Thomas spoke before the Section on the subject, "Physical Chemistry."

D. M. Buck, of the American Sheet and Tin Plate Co., gave an illus-

trated lecture, September 24, before the Section on the manufacture of tin plate.

At a business meeting held on October 15, the following officers were elected for the year: C. A. Nash, *Chairman*; C. N. Davidson, *Vice-Chairman*; W. H. Kloppenburg, *Secretary*; E. J. Kern, *Treasurer*; J. A. Wilson and G. N. Prentiss, *Councilors*.

On January 14, Edwin J. Kern, *Treasurer* of the Section, spoke before the regular meeting on the subject, "The Estimation of Tannin."

WM. H. KLOPPENBURG, *Secretary*.

#### MINNESOTA SECTION.

At the 90th meeting of the Section, held on December 3, Julius Stieglitz, of the University of Chicago, spoke on "The Theory of Color Production." Attendance, 350.

On January 6, J. F. McClendon, of the School of Medicine, University of Minnesota, addressed the Section on "The Chemical Basis of Education."

L. M. HENDERSON, *Secretary*.

#### NEBRASKA SECTION.

The Section has elected the following officers for 1921: Ernest Anderson, *Chairman*; W. S. Frisbie, *Vice-Chairman*; S. B. Arenson, *Secretary-Treasurer*; F. W. Upson, *Councilor*; H. G. Deming, H. A. Durham, and D. J. Brown, *Executive Committee*. Attendance at December 14th meeting, 50%.

B. CLIFFORD HENDRICKS, *Secretary*.

#### NEW YORK SECTION.

The program for the regular meeting held on January 7 was as follows: "New Points of Contact Between University and Industry," by Warren K. Lewis, and "Heat Factors of Oil Shale Distillation," by R. H. McKee and E. E. Lyder.

HERBERT G. SIDDEHOTTOM, *Secretary*.

#### NORTHEASTERN SECTION.

The 163rd regular meeting of the Section occurred on January 14, when Jaques Bronfenbrenner, assistant professor of Preventive Medicine and Hygiene at the Medical School of Harvard University, spoke on "Some Chemical Problems in Bacteriology," illustrated by lantern slides.

L. F. HAMILTON, *Secretary*.

#### OMAHA SECTION.

At the 3rd meeting of the Section, held on October 19, papers were presented as follows: "The Dynamics of Catalase Action," by A. Morgulis; and "Some Observations on Corrosion in Boilers," by W. M. Barr.

The 4th meeting was held on November 16, at which time Gerald Wendt, of the University of Chicago, addressed the Section of "Electrometric Filtration."

On December 14, John T. Myers presented a paper before the members of the Section, his subject being, "Sulfur Producing Bacteria."

The following officers have been elected by the Section for the year 1921: H. A. Senter, *Chairman*; Dean Yohe, *Vice-Chairman*; E. M. Partridge, *Secretary-Treasurer*; Wm. M. Barr, *Councilor*; C. F. Crowley, J. A. Land and R. W. Savidge, *Executive Committee*.

The 6th meeting of the Section was held at the Creighton Dental College in January, at which time a paper was presented by Wm. G. Haynes on the "Inspection of Oils and Paints."

E. M. PARTRIDGE, *Secretary*.

#### PITTSBURGH SECTION.

At the 167th regular meeting of the Section, on November 18, Duncan MacRae, of the Westinghouse Electric and Manufacturing Co., spoke on "The Manufacture of Incandescent Tungsten Filament Bulbs."

At the 168th regular meeting, held on December 16 at the Mellon Institute, F. C. Binnall, Engineer for the General Oil Gas Corporation of New York City, addressed the members on "The Dayton Oil Gas Process."

On January 20, R. B. Gilmore spoke before the Section on "Some Problems in Graphite Crucible Manufacture."

G. W. JONES, *Secretary*.

#### RHODE ISLAND SECTION.

A joint meeting was held with the Providence Engineering Society on December 21. Ellwood Hendrick spoke on the subject, "Chemistry for Everyman."

On January 21, Norman E. Holt addressed the Section on "The Bucher Process as Utilized by the Ordnance Department During the War."

HERBERT F. DAVISON, *Secretary*.

#### ROCHESTER SECTION.

The 116th meeting of the Section occurred on January 10, at the University of Rochester. William Webb, of the Eastman Kodak Company, spoke on "Camphor, Natural and Synthetic."

ERLE M. BILLINGS, *Secretary*.

#### SAVANNAH SECTION.

The regular monthly meeting of the Section was held on December 16, when the following papers were presented: "The Economic Loss from Principal Causes of Death in Savannah with Special Reference to Malaria," by Alfred Larsen; "The Economic Loss from Syphilis, with Some Remarks on the Methods of Diagnosis of the Disease," by V. H. Bassett; and "The Wassermann Complement Fixation test for Syphilis," by Daniel Secklinger. All papers were illustrated by charts and pictures.

At this meeting the following officers for 1921 were elected: Herbert S. Bailey, *Chairman*; Joseph Callaway, Jr., *Vice-Chairman*; Herbert P. Stack, *Secretary-Treasurer*; and F. N. Smalley, *Councilor*. Attendance, 38%.

HERBERT P. STACK, *Secretary*.

## SOUTHEAST TEXAS SECTION.

The following officers for 1921 have been elected by the Section: H. B. Weiser, *Chairman*; L. S. Bushnell, *Vice-Chairman*; P. S. Tilson, *Secretary*; L. S. Howell, *Treasurer*; F. W. Bushong, *Councilor*.

P. S. TILSON, *Secretary*.

## ST. LOUIS SECTION.

At the regular December meeting, the Section elected the following officers for 1921: F. W. Russe, *Chairman*; L. F. Nickell, *Vice-Chairman*; H. A. Carlton, *Secretary*; O. H. Pierce, *Treasurer*; L. McMaster and P. A. Shaffer, *Councilors*.

L. G. Blakeslee read a paper on "The Bearing of Some of the Federal Laws on the Chemical Business," before the regular meeting of the Section, January 3.

H. A. CARLTON, *Secretary*.

## SYRACUSE SECTION.

The first extra winter meeting of the Section was held on January 7, when C. G. Derick addressed the members on "Methods of Attacking a Research Problem." Attendance,  $33\frac{1}{8}\%$ .

BYRON W. GRIMES, *Secretary*.

## UNIVERSITY OF MICHIGAN SECTION.

At the annual business meeting of the Section, held on December 14, the following officers were elected for 1921: A. H. White, *Chairman*; C. C. Meloche, *Secretary-Treasurer*; H. H. Willard, *Councilor*; C. S. Schoepfle, F. E. Bartell, W. L. Badger, *Executive Committee*. Attendance, 40%.

R. J. CARNEY, *Secretary*.

## UNIVERSITY OF MISSOURI SECTION.

The annual meeting of the Section was held on December 17, when the following papers were presented: "Coumarin Extraction," by R. M. Smith; and "Carbon Determinations in Plant Tissues," by T. E. Friedemann. Officers for the year 1921 were elected, as follows: S. Calvert, *Chairman*; W. J. Robbins, *Vice-Chairman*; H. D. Hooker, Jr., *Secretary*; L. D. Haigh, *Treasurer*; and C. R. Moulton, *Treasurer*.

HENRY D. HOOKER, JR., *Secretary*.

## VIRGINIA SECTION.

The 39th meeting of the Section was held on January 21, when E. C. L. Miller spoke on "Hydrogen-Ion Concentration and its Determination." Following the lecture, moving pictures pertaining to chemistry, loaned by the Bureau of Commercial Economics, were exhibited. Attendance at December meeting, 28%.

ROBT. F. MCCracken, *Secretary*.

## WASHINGTON, D. C., SECTION.

The 313th meeting of the Section was held at the Cosmos Club. The address of the evening was delivered by R. C. Tolman, director of the Nitrogen Fixation Laboratory, Ordnance Bureau, War Department, his subject being "The Third Law of Thermodynamics."

J. B. REED, *Secretary*.

# Proceedings.

## COUNCIL.

Dr. E. F. Smith, President of the American Chemical Society, has changed the name of the Committee on Institute for Drug Research to the Committee on Institute for Chemo-Medical Research, and has appointed Dr. C. L. Alsberg, of Washington, D. C., to fill the vacancy on the Committee created by the resignation of Dr. P. A. Levene.

## Auditors' Report.

New York, January 28, 1921.

DR. J. E. TEEPLE, *Chairman Finance Committee*,  
American Chemical Society,  
50 East 41st Street, New York City.

DEAR SIR:

Pursuant to your request, we have made an audit of the books of account of the American Chemical Society, kept by its Treasurer, for the year ending December 31, 1920, and submit herewith the accompanying Condensed General Balance Sheet as of December 31, 1920, and Statement of Cash Received and Disbursed between January 1, and December 31, 1920—marked Exhibit "A" and Exhibit "B," respectively, which we have prepared therefrom; and hereby

CERTIFY that such statements correctly reflect the financial condition of the Society at December 31, 1920 and its financial transactions during the year, as shown by the books of account.

Yours very truly,

MCCULLOH AND BROWN,  
*Certified Public Accountants.*

## AMERICAN CHEMICAL SOCIETY.

### CONDENSED GENERAL BALANCE SHEET—DECEMBER 31, 1920.

#### ASSETS.

#### INVESTMENTS:

Special investment fund:		Market value.	
\$1,000 Brooklyn Rapid Transit 7% Notes, Due July 1, 1922.....	\$	400.00	\$ 1,000.00
1,000 Hocking Valley Railway 1st Mortgage 4½%, Due July 1, 1999..		690.00	1,000.00
6,000 Illinois Central-Chicago, St. Louis and New Orleans Joint 1st Re- funding Mortgage 5%, Due December 1, 1963.....		4,792.50	6,000.00
1,000 Northern Pacific Great Northern- Chicago, Burlington and Quincy 4%, Due July 1, 1921.....		960.00	1,000.00

1,000 New York Connecting Railway 1st Mortgage 4 <sup>1</sup> / <sub>2</sub> %, Due August 1, 1953.....	755.00	1,000.00
2,000 Atlas Portland Cement 6%, Due March 1, 1925.....	1,760.00	2,000.00
2,000 Corporate Stock City of New York 4 <sup>1</sup> / <sub>2</sub> %, Due June 1, 1965.....	1,840.00	2,000.00
5,000 New York Central Refunding & Improvement 4 <sup>1</sup> / <sub>2</sub> %, Series "A," Due October 1, 2013.....	3,700.00	5,000.00
10,000 United States Steel Corporation 5%, Due April 1, 1963.....	9,300.00	10,000.00
15,000 United States Liberty 2nd 4 <sup>1</sup> / <sub>4</sub> %, Due 1942.....	12,765.00	14,608.00
20,000 United States Liberty 3rd 4 <sup>1</sup> / <sub>4</sub> %, Due 1928.....	17,596.00	19,400.00
15,000 United States Liberty 4th 4 <sup>1</sup> / <sub>4</sub> %, Due 1933-1938.....	12,780.00	14,604.00
10,000 United States Victory 4 <sup>3</sup> / <sub>4</sub> %, Due 1922-1923.....	9,600.00	10,000.00
10,000 New York Telephone Company 6%, Due February 1, 1949.....	8,700.00	9,987.50
10,000 United Kingdom of Great Britain and Ireland 5 <sup>1</sup> / <sub>2</sub> %, Due February 1, 1937.....	8,300.00	9,875.00
10 Shares Chemical Foundation Inc. Stock—(Subscription Receipt Central Union Trust Company.	1,000.00	1,000.00
Total.....	\$ 94,938.50	\$108,474.50

## Life Membership Fund:

\$1,000 United States Liberty, 2nd 4 <sup>1</sup> / <sub>4</sub> %, Due 1942.....	\$ 851.00	\$ 908.75
1,000 United States Liberty, 4th 4 <sup>1</sup> / <sub>4</sub> %, Due 1933-1938.....	852.00	906.95
1,000 Corporate Stock City of New York 3 <sup>1</sup> / <sub>2</sub> %, Due November 1, 1928...	890.00	1,000.00
2,000 Mutual Union Telegraph 5%, Due May 1, 1941.....	1,520.00	2,000.00

Total.....	\$ 4,113.00	4,813.70
------------	-------------	----------

## Report of the Treasurer.

New York City, N. Y., February 10, 1921.

The preceding report of the Auditors gives the Balance Sheet of your Society as of December 31, 1920 and the total receipts and disbursements for the year 1920.

In examining the Balance Sheet we should remember that the Morris Loeb Fund and the income from it does not belong in any way whatever to the American Chemical Society. We are simply the trustees of this Fund and hand over all the income to the Smithsonian Institution for maintaining the Morris Loeb Museum. In the same way we should remember that the Life Membership Fund does not belong to the American Chemical Society for any purpose whatever excepting for furthering research work if that should be undertaken at any time, and that the income from this Fund does not belong to the Society excepting for paying the dues of living life members. We are simply the custodian of these two Funds and cannot use them or their income in any way for the general purposes of the Society. The Special Investment Fund represents our real surplus. You will note that this has not been changed in any way during the year either by purchase or sale. Its market value as indicated, is less than it was a year ago simply on account of the depreciation in value of all securities. The Office Furniture and Fixtures, and Publica-

tions are carried at the same figures as they were a year ago. We have no liabilities excepting our liability for the proper handling of our Trust Funds, consequently our situation at the end of the year 1920 and at the end of the year 1919 may be easily compared by comparing our current assets.

At the end of 1919 our cash assets were \$27,281.00. From this, however, we must deduct \$6,016.03 income from the Morris Loeb Fund which was included in this cash item, and \$1,807.59 income from the Life Membership Fund—a total of \$7,823.62. We must also deduct \$20,000 which we had already used out of 1920 funds. This left a cash deficit of \$542.62.

At the end of 1920 we had cash on hand of \$1,526.39, from which must be deducted \$464.52 Life Membership Income, and from which must further be deducted \$35,000 which we had used out of 1921 funds, leaving a cash deficit December 31, 1920 of \$33,938.13.

A comparison of the figures for the two years, then, shows that our cash position at the end of 1920 was \$33,395.51 worse than it was twelve months previously, and the only offset to this is that our Accounts Receivable from advertising had increased about \$10,000 during the year.

If we now take the question of Receipts and Disbursements and eliminate all Trust items, all short term transactions which were begun and concluded during the year, we get a net operating account of the Society's activities for the year 1920 as follows:

#### RECEIPTS.

Membership Subscriptions.....	\$140,482.00
Subscriptions, non-members.....	15,863.98
Back Numbers, net.....	5,491.55
Directories.....	18.00
Reprints.....	1,626.81
Decennial Index.....	1,699.00
Postage.....	3,735.46
Advertising, net.....	28,605.98
Interest.....	7,499.12
<b>TOTAL.....</b>	<b>\$205,021.90</b>

#### DISBURSEMENTS.

##### *Journal:*

Salaries.....	\$2,083.04
Expenses.....	499.23
Printing.....	42,709.13
	<hr/>
	\$ 45,291.40

##### *Chemical Abstracts:*

Salaries.....	18,461.18
Expenses.....	1,124.71
Printing.....	62,435.82
	<hr/>
	82,021.71

*Industrial Journal:*

Salaries.....	19,294.53	
Expenses.....	4,905.43	
Printing.....	43,656.39	
		<hr/>
		67,856.35
News Service.....		8,078.69

Secretary's Office, net.....		19,964.90
Treasurer's Office.....		3,040.30
President's Office.....		348.98
General Meetings.....		1,703.48
Monographs.....		2,151.14
Miscellaneous.....		946.76
Total.....		\$239,025.26
Deduct Receipts.....		205,021.90

Net Operating Deficit..... \$ 34,003.36

In our Finance Committee's report of September 2, 1920, which was presented at the Chicago Meeting, we estimated that this deficit would be \$27,000 if no further increases in printing occurred, but increases in cost of printing did occur, resulting in the \$34,000 deficit for the year. Hence the increase in dues to \$15.00.

If we assume that the membership dues received represented 14,000 paying members, our Receipts and Disbursements per year are distributed as follows:

## RECEIPTS.

Dues.....	\$10.00
Advertising, net.....	2.04
Other income.....	2.57
	<hr/>
Total.....	\$14.61

## DISBURSEMENTS.

Journal.....	\$ 3.23
Abstracts.....	5.84
Industrial Journal.....	4.84
News Service.....	0.57
Local Sections.....	0.55
Secretary's Office.....	1.43
Treasurer's Office.....	0.22
President's Office.....	0.02
General Meetings.....	0.12
Monographs.....	0.15
Miscellaneous.....	0.07

Total..... \$17.04

leaving a net deficit of \$2.43 per member, and indicating that each member, for his \$10.00 dues, received \$17.04 either in Society Journals or Society activities.

JOHN E. TREEPLE, *Treasurer.*

## MEMBERS ELECTED BETWEEN JANUARY 15 AND FEBRUARY 15, 1921.

- Abbett, James M., 1106 Colusa Ave., Berkeley, Calif.  
 Abbett, Raymond F., 923 Elberon Ave., Cincinnati, O.

 Weber, Karl B., Johnson St. & Mancher Place, Middle Village, L. I., N. Y.  
 Werbelowsky, Isidor, 1054 Park Place, Brooklyn, N. Y.  
 White, C. Eldon, P. O. Box 64, Palo Alto, Calif.  
 Whittaker, Colin W., 3519 Lowell St., N. W., Washington, D. C.  
 Williams, Ralph D., 207 W. Main St., Grove City, Pa.  
 Wilson, J. Stuart, 28 Barton Ave., Toronto, Ont., Canada.  
 Wilson, M. M., 3516 Bosworth Ave., Chicago, Ill.  
 Winslow, Earl H., 43 Harvard St., Worcester, Mass.  
 Wong, King W., 115 University Station, Urbana, Ill.  
 Wood, George H., Jr., 54 Jenks Ave., Central Falls, R. I.  
 Wu, C. L., c/o Mr. Y. T. Chang, 20 Elgin Road, Shanghai, China.  
 Yang, Shao T., 411 Thurston Ave., Ithaca, N. Y.  
 Yee, Martin A., Chem. Dept., Chicago Univ., Chicago, Ill.

#### CORPORATE MEMBERS.

- American Cotton Oil Company, 65 Broadway, New York, N. Y.  
 Dahlberg & Company, Inc., 1829 Bordeaux St., New Orleans, La.  
 Rhodia Chemical Company, 89 Fulton Street, New York, N. Y.  
 Semet-Solvay Company, Syracuse, N. Y.  
 S. K. F. Research Laboratory, Front St. & Erie Ave., Philadelphia, Pa.  
 Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.

#### MEETINGS OF THE SECTIONS.

[Full accounts of all meetings should be sent to Secretary Charles L. Parsons, 1709 G St., N. W., Washington, D. C.]

##### AMES SECTION.

On January 13, Fred Upson, head of the Department of Chemistry, University of Nebraska, addressed the Ames Section on "The Life and Researches of J. U. Nef."

H. L. MAXWELL, *Secretary.*

##### CALIFORNIA SECTION.

The 120th regular meeting of the Section occurred on January 28, when the following program was given: "The Chemical Effect of Alpha Particles," by S. C. Lind, physical chemist of the U. S. Bureau of Mines; and "Refining of Zinc by Electrolysis," by Oliver C. Ralston, metallurgist, of the U. S. Bureau of Mines.

LLOYD W. CHAPMAN, *Secretary.*

## CHICAGO SECTION.

On January 21, Paul Nicolas Leech, of the American Medical Association, spoke before the Section on the subject of "Home Remedies." This meeting was designated as Ladies' Night, being the third of a series of meetings given over to topics of interest to members and their wives.

At the regular meeting of the Section, held on February 18, L. V. Redman delivered a lecture on "Phenol Condensation Products." The discovery, development, manufacture and application of phenol condensation products, were covered.

S. L. REDMAN, *Secretary*.

## CINCINNATI SECTION.

The 239th regular meeting of the Section was held in the Chemistry Auditorium of the University of Cincinnati on January 29. The following program was given: "A Simple Method of Determining the Refractive Index of a Liquid by Means of a Microscope," by O. C. Von Schlichten, Geology Department, University of Cincinnati; and "On the Nature of Vegetable Tanning," by G. D. McLaughlin, director of the tanning research department of the University of Cincinnati.

At the 240th regular meeting of the Section, on February 9, C. R. Bragdon, chemical superintendent of the Varnish Works of the Ault & Wiborg Co., spoke on "The Transition Period in Varnish Manufacture."

C. H. LUND, *Secretary*.

## CLEVELAND SECTION.

On January 25, W. Forsythe, of the National Lamp Works, addressed the Section on the subject of "Pyrometers and High Temperature Measurement." Attendance, 60%.

HAROLD S. BOOTH, *Secretary*.

## COLORADO SECTION.

The regular meeting of the Section, held on January 24, in the Denver Public Library, was addressed by H. Mendelson, of the Great Western Sugar Company, on "Chemistry in Agriculture of To-day."

RUTH B. VERTREES, *Secretary*.

## CONNECTICUT VALLEY SECTION.

On January 22, H. S. Miner, of the Welsbach Co., spoke before the Section on "Industrial Lighting."

John S. Shearer, of Cornell University, addressed the members of the Section on February 5, his subject being "Some Recent Applications of X-Rays in the Study of Metals." Attendance, 350.

G. B. HOGABOOM, *Secretary*.

## CORNELL SECTION.

L. B. McMillan, consulting engineer of the Johns-Manville Co., addressed the Section on January 19, his subject being "Heat Insulators."

The regular meeting of the Section occurred on January 25, when John E. Teeple, consulting chemist and chemical engineer, and Treasurer of

the American Chemical Society, spoke on "Chemistry and Engineering in American Potash Manufacture."

F. R. GEORGIA, *Secretary*.

#### DETROIT SECTION.

The 122nd meeting of the Section was held on January 19, when H. P. Kimber of the Pittsburgh Electric Furnace Co., spoke on "Synthetic Iron."

WM. B. TEMPLETON, *Secretary*.

#### EASTERN NEW YORK SECTION.

On January 28, J. C. McLennan, director of the Physical Laboratory at the University of Toronto, addressed the Section on "Helium, Its Production and Uses." Attendance, 61%.

F. K. Richtmeyer, of Cornell University, spoke before the Section, February 18, on "Some Problems of Physiological Optics." Attendance, 46%.

MARY R. ANDREWS, *Secretary*.

#### GEORGIA SECTION.

The regular meeting of the Section occurred on January 19, when E. M. Symmes, of the Hercules Powder Co., gave an address before the members on the subject, "The Manufacture of Dynamite and Gelatin," illustrated by moving pictures.

J. S. BROGDON, *Secretary*.

#### IOWA SECTION.

On February 19, the following program was carried out by the Section at Cedar Rapids, Iowa: "Electromotive Forces and Free Energy of Dilution of Potassium Bromide," by H. B. Hart; "The Adsorption of Dyes by Pleistocene Clays," by J. N. Pearce; "Source of Sodium Chloride in Rain and Snow," by Nicholas Knight; "Animal Utilization of Pentose," by E. W. Rockwood; and "Further Observations of the Migration of Acyl," by J. R. Couture and L. Chas. Raiford.

L. C. RAIFORD, *Secretary*.

#### KANSAS CITY SECTION.

The Kansas City Section held its January meeting on January 22, when the following program was given: "Some Aspects of Chemical Manufacture," by W. H. Leverett, of the National Zinc Company; and "Chemistry of Salvarsan," by Ray Brewster, of the University of Kansas.

On February 9, Wm. H. Walker, of the Massachusetts Institute of Technology, spoke before the members on "Chemistry in the Last War and in the Next." Attendance, 51%.

LEE E. CLARK, *Secretary*.

#### LEXINGTON SECTION.

The 67th meeting of the Section occurred on January 27, when the following papers were read: "Preparation and Selection of Crystals for Measurement," by F. E. Tuttle; and "The Microscopic Examination of Feeding Stuffs and Drugs," by E. J. Jackson.

S. D. AVERITT, *Secretary*.

## LOUISVILLE SECTION.

On January 25, E. M. Symmes, of the Hercules Powder Company, gave a talk before the Section on "The Manufacture of Dynamite and Gelatin."

C. E. GEIGER, JR., *Secretary*.

## MAINE SECTION.

The annual meeting of the Section occurred on January 19, when L. J. Waldbauer spoke on "Moving Picture Films." The following officers were chosen for 1921: C. A. Brautlecht, chairman; J. M. Bartlett, vice-chairman; L. J. Waldbauer, secretary-treasurer; and A. B. Larcher, councilor. Attendance, 30%.

B. F. BRANN, *Secretary*.

## MARYLAND SECTION.

The 47th meeting of the Section was held on January 28. Robert W. Wood, of Johns Hopkins University, spoke on "High Power Fluorescence and Phosphorescence and their Relation to Chemical Change."

C. CLIFTON HOWES, *Secretary*.

## MIDLAND SECTION.

On February 9, Mr. Paul Cottringer, of the Dow Chemical Company, addressed the Section on "The Manufacture of Synthetic Phenol."

C. C. KENNEDY, *Secretary*.

## MILWAUKEE SECTION.

At the meeting of the Section, held on February 18, Carl S. Miner, of Chicago, spoke before the members on "Patents and Their Relation to Chemists and Chemical Industry."

WM. H. KLOPPENBURG, *Secretary*.

## MINNESOTA SECTION.

On February 18, William Moore, of the University of Minnesota, addressed the Section on the subject, "Theory of Adherence of Arsenical Sprays."

L. M. HENDERSON, *Secretary*.

## NASHVILLE SECTION.

The 10th meeting of the Nashville Section was held on January 24. E. M. Symmes spoke to the members on "The Manufacture of Dynamite and Gelatin."

H. A. WEBB, *Secretary*.

## NEBRASKA SECTION.

The 95th meeting of the Section, on January 20, was addressed by W. S. Frisbie, of the Bureau of Foods, Drugs and Oils of the State of Nebraska, his subject being "Some of the Problems of a State Chemist." Attendance, 33 $\frac{1}{3}$ %.

At a special meeting, held on January 22, F. W. Upson and T. J. Thompson reported on substituted alkyl phenyl succinic acids. Attendance, 30%.

On February 24, Victor Lenher, professor of chemistry at the Uni-

versity of Wisconsin, who was a guest of the University of Nebraska and the Local Section, spoke to the members on "Selenium Oxychloride."

S. B. ARNSEN, *Secretary*.

#### NEW HAVEN SECTION.

At the annual meeting of the Section, held on January 28, S. F. Acree, spoke on "The Measurement and Significance of Hydrogen-Ion Concentration in Chemical and Biological Work."

BLAIR SAXTON, *Secretary*.

#### NORHEASTERN SECTION.

The 164th regular meeting of the Northeastern Section was held on February 11, when the following program was given: "The Uses of Silicate of Soda in Industry," by James G. Vail, chemical director of the Philadelphia Quartz Company; and "The Cold Storage of Food in Massachusetts," by Hermann C. Lythgoe, director of the division of food and drugs of the Public Health of the Commonwealth of Massachusetts.

I. F. HAMILTON, *Secretary*.

#### NORTH CAROLINA SECTION.

At a call meeting of the Section, held on January 14 in Raleigh, N. C., the members of the North Carolina Section were addressed by E. M. Symmes, chemical director of the Hercules Powder Co., on the subject of "The Manufacture of Dynamite and Gelatin."

LELAND B. RHODES, *Secretary*.

#### OMAHA SECTION.

The 7th meeting of the Section, on February 8, had as its speaker H. H. Nicholson, mining engineer, formerly head of the Department of Chemistry, University of Nebraska.

E. M. PARTRIDGE, *Secretary*.

#### PHILADELPHIA SECTION.

On January 20, Harrison E. Howe, chairman of the Division of Research Extension, National Research Council, addressed the Section on "The Importance of Organized Science to Chemistry."

At the regular monthly meeting of the Section, held on February 17, Wm. J. Gies, of Columbia University, spoke on "The Dentrifice Problem Viewed from the Standpoint of Recent Chemical Findings." Attendance, 17%.

J. HOWARD GRAHAM, *Secretary*.

#### PITTSBURGH SECTION

The 169th meeting of the Section was held on January 20, when R. B. Gilmore, ceramic engineer for the Vesuvius Crucible Co., spoke on "Some Problems in Graphite Crucible Manufacture."

GEFHART STEHRMAN, *Secretary*.

#### PUGET SOUND SECTION.

The Section has as its speaker, on January 20, J. F. Plaskeet, director of the Dominion Astrophysical Observatory at Victoria, B. C., who lectured on the subject, "The Chemistry of the Stars."

R. W. ELLISON, *Secretary*.

## ROCHESTER SECTION.

On February 7, F. R. Baxter, chief chemist of the Vacuum Oil Company, gave an illustrated lecture before the Section on "The Manufacture of Barrels."

ERLE M. BILLINGS, *Secretary*.

## ST. LOUIS SECTION.

The regular meeting of the Section was held on February 7, and was addressed by A. H. Compton, professor of physics at Washington University, on the subject, "Micro-World of the Atom."

H. A. CARLTON, *Secretary*.

## SAVANNAH SECTION.

At a special meeting of the Section, on January 18, the members were favored by an illustrated lecture on "The Manufacture of Dynamite and Gelatin," by E. M. Symmes, of the Hercules Powder Company. Attendance, 35.

The 5th regular meeting of the Section was held on January 27, when the following papers were presented: "The Fertilizer Industry," by E. H. Armstrong; "Potash," by P. H. Carter; and "Acid Phosphate," by P. McG. Shuey. Attendance, 42.

HERBERT P. STRACK, *Secretary*.

## SOUTHERN CALIFORNIA SECTION.

On January 27, Francis J. Pease, of the Mt. Wilson Observatory, addressed the Section on the "100-inch Reflector; its Construction and Some of the Work that is Being Done With it."

H. L. PAYNE, *Secretary*.

## TOLEDO SECTION.

At a joint meeting, between the Local Section and the Toledo Section of the American Society of Mechanical Engineers, the Toledo Case Club, the Doherty Men's Fraternity, and other engineering bodies, held on February 18, Dayton C. Miller, of the Case School of Applied Science, gave an illustrated lecture on "Sound Wave Photography."

R. W. ERWIN, *Secretary*.

## UNIVERSITY OF ILLINOIS SECTION.

The 112th regular meeting of the Section was held on January 19, at which time A. M. Buswell spoke to the members on "Some Recent Experiments in Dewatering of Sludges and Slimes."

At the 113th meeting of the Section, held on February 16, R. S. Moore, of the U. S. Bureau of Mines, spoke on the subject of "Helium."

S. A. BRALEY, *Secretary*.

## UNIVERSITY OF MICHIGAN SECTION.

On January 21, the members of the Section heard an address by L. H. Cone, of the National Aniline and Chemical Co. C. C. MELOCHE, *Secretary*.

## UNIVERSITY OF MISSOURI SECTION.

The 97th meeting of the Section occurred on February 4, when H. D. Hooker, Jr., read a paper on "The Function of Pentosans in Plants."

HENRY D. HOOKER, JR., *Secretary*.

## VIRGINIA SECTION.

The 40th meeting of the Section, on February 18, had as its speaker, Harrison E. Howe, who spoke on "The Division of Research Extension and its Relation to Chemistry."

ROBT. F. McCRACKAN, *Secretary*.

## WASHINGTON, D. C., SECTION.

The 315th meeting of the Section was held on February 10, at the Cosmos Club, when the following symposium on fertilizer chemistry was presented: "The Present American Fertilizer Industry," by Wm. D. Hurd; "Phosphates and Phosphoric Acid Production," W. H. Waggaman; "The Potash Situation of To-day," by F. W. Brown; "Nitrogen Resources, Possibilities and Requirements," by Capt. D. P. Gaillard; "Fertilizer Utilization, Coördination of Soil, Plant and Fertilizer," Oswald Schreiner; and "Concentrated Chemical Fertilizers, a Future Prospect," by R. O. E. Davis.

J. B. REED, *Secretary*.

## WISCONSIN SECTION.

On January 26, W. E. Tottingham addressed the Section on "The Effect of Climate on the Chemical Composition of Plants."

V. L. BOHNSON, *Secretary*.

## DECEASED.

Belden, A. W., Jones & Laughlin Steel Co., Woodlawn, Pa., died December 14, 1920.

Broeker, C. E., 5520 Blackstone Ave., Chicago, Ill.

Dewey, Frederic P., Mint Bureau, U. S. Treasury, Washington, D. C., died February, 11, 1921.

Cleary, Martin J., 1055 Loyola Ave., Chicago, Ill.

Kunz, Herman W., 1240 E. 71st St., Cleveland, O., died May, 1920.

Moore, Russell W., 44 W. 77th St., New York City, died July 31, 1920.

Yocum, John H., 325 Academy St., Newark, N. J., died Jan. 27, 1921.

# Proceedings.

## COUNCIL.

President Smith has been requested by Mrs. William Brown Meloney, who is in charge of the reception of Madame Curie in this country, to head a Reception Committee of the American Chemical Society and to appoint additional members. Doctor Smith has appointed the following, Leo H. Baekeland, Wilder D. Bancroft, B. B. Boltwood, Marston T. Bogert, Charles F. Chandler, Charles H. Herty, S. C. Lind, R. B. Moore, W. H. Nichols, W. A. Noyes, Charles L. Parsons, Ira Remsen, T. W. Richards, J. Enrique Zanetti.

In compliance with a request of the American Mining Congress that a representative of the American Chemical Society be appointed to meet with them on March 10, at 10.00 A.M., at the Biltmore Hotel, New York City, President Smith appointed Dr. Charles Baskerville.

### MEMBERS ELECTED BETWEEN FEBRUARY 15 AND MARCH 15, 1921.

Abernethy, Raymond J., 597-32nd St., Oakland, Calif.  
Aiken, Hugh K., Jr., "Hillcrest," Ithaca, N. Y.  
Allen, Charles J., 3738 Edwards Rd., Hyde Park, Cincinnati, O.  
Alsberg, Julius, 140 South Dearborn St., Chicago, Ill.  
Anthes, John F., 2132-85th St., Brooklyn, N. Y.  
Attisani, Vincent J., 39 Seventh St., New Rochelle, N. Y.  
Aultman, Paul M., 1418 Pine St., Norristown, Pa.  
Barbehenn, J. Berthold, 150 W. Broad St., Bethlehem, Pa.  
Beekley, Henry L., 1929 Kinney Ave., Cincinnati, O.  
Bellamy, B. C., 1102 Grand Ave., Laramie, Wyo.  
Bennett, John A., 168 Gold St., Dover, N. J.  
Bertram, S. H., Burgem. Meinessplein 6A, Rotterdam, Holland.  
Blanke, D. C., 49 Claremont Ave., New York, N. Y.  
Bode, J. Carl, 411 Hawthorne Ct., Madison, Wisc.  
Bodenius, J. E., 3210 Arthington Ave., Chicago, Ill.  
Bosman, V., Box 153, University Station, Urbana, Ill.  
Bowman, Jay, 6421 Harper Ave., Chicago, Ill.  
Bradford, James A., Findlay College, Findlay, O.  
Brower, P. V., 103 Andrew Pl., W. Lafayette, Ind.  
Brown, Robert E., Miami University, Oxford, O.  
Burgess, Wayland M., 21 Elbridge St., Worcester, Mass.  
Burr, G. O., Room 16, Y. M. C. A., Wichita, Kans.  
Busch, John S., 5005 Lyndale Ave. So., Minneapolis, Minn.  
Busch, K. G. A., 2424 Sherwood Rd., Bexley, Columbus, O.  
Bush, Russell J., Colfax, Ind.  
Byck, Lawrence C., 227 Kearny Ave., Perth Amboy, N. J.  
Caldeira, Fred D., care Presbyterian Hospital, Chicago, Ill.  
Canter, Vernon C., Box 117, Bradford, Pa.  
Cargill, Everett C., 5814 Forbes St., Pittsburgh, Pa.  
Carlson, Carl E., North Main St., West Hartford, Conn.  
Carlson, Gustav, Suite No. 7, 282 Massachusetts Ave., Cambridge 39, Mass.  
Cervi, Armando, 116 Riverside Drive, New York, N. Y.  
Claypool, Walter, care The Texas Co., Bayonne, N. J.  
Cocksedge, H. E., 7 Dyar Terrace, Wintonington, Northwich, Cheshire, England.  
Cohen, Abraham, 86 Phillips St., Boston, Mass.  
Collins, O. C., 1964 Ryons St., Lincoln, Nebr.  
Cresson, Lionel, Netherlands Gutta Percha Co., Pasir Panjang, Singapore, Straits Settlements.  
Culpepper, C. W., H. P. Bur. of Plant Industry, U. S. Dept. of Agr., Washington, D. C.  
Dayton, Walter C., 581 Broad St., Newark, N. J.  
De Bar, H. L., care F. W. Freeborn Eng. Corp., Tulsa, Okla.  
Deterding, Henry C., Mueller Mfg. Co., Decatur, Ill.  
Dibble, Marion A., 143 E. Butler St., Adrian, Mich.  
Ellenberg, J. M., 16 West Lincoln St., Shamokin, Pa.  
Ennis, Marjorie, 6122 Winthrop Ave., Chicago, Ill.

- Flurschein, Bernard, Rushmoor, Fleet, Hampshire, England.  
 Friend, J. Newton, Technical School, Suffolk St., Birmingham, England.  
 Gadd, Edna D., 13 Main St., Plymouth, N. H.  
 Gageby, P. A., 1956 W. 94th St., Chicago, Ill.  
 Gallun, Albert F., Jr., 620 Newberry Blvd., Milwaukee, Wis.  
 Gast, P. R., N. Y. State College of Forestry, Syracuse University, Syracuse, N. Y.  
 Gibson, Donald C., Martinez, Calif.  
 Giddings, W. W., 150 Langdon St., Madison, Wisc.  
 Glockler, George, University of California, Gillman Hall, Berkeley, Calif.  
 Grinditch, Wm. H., 4003 York Road, Philadelphia, Pa.  
 Gross, Ira C., 711 Baldrige St., North Braddock, Pa.  
 Guthrie, Horace B., 64 Putnam St., Buffalo, N. Y.  
 Hall, Archibald J., care Silver Springs Bleaching & Dyeing Co., Timberbrook, Congleton, Cheshire, England.  
 Hall, William W., 80 Waterman St., Providence, R. I.  
 Harrington, John G., Box 391 Central Park Station, Houston, Tex.  
 Hayashi, Fukuo, 102 West 123rd St., New York, N. Y.  
 Henke, Herluf A., 3244 Herndon St., Chicago, Ill.  
 Henley, Andrew T., Lady's Well Brewery, Cork, Ireland.  
 Hermanowich, Chas., 1855 S. California Ave., Chicago, Ill.  
 Hockman, George B., College of Chemistry, Univ. of Md., College Park, Md.  
 Holder, E. P., Twentieth Century Laundry Co., Inc., 251 Third Ave., New York, N. Y.  
 Hollenback, Rand P., 3134 N. High St., Columbus, O.  
 Hopkins, Harris H., 704 S. Park St., Kalamazoo, Mich.  
 Jackson, Henry, Jr., 929 St. Paul St., Baltimore, Md.  
 Janvier, Meredith M., 23 West Lawn, University, Va.  
 Joffe, Moris, 1104 W. Clark St., Urbana, Ill.  
 Johns, Reinhold P., 227 Central Ave., West Hoboken, N. J.  
 Kaiser, Harold F., 214 N. Taylor Ave., Oak Park, Ill.

## CORPORATE MEMBERS.

Chicago Crucible Co., 2525 Clybourn Ave., Chicago, Ill.  
 Hirsch Laboratories, Inc., 50 East 41st St., New York, N. Y.  
 Roxana Petroleum Corp., Wood River, Ill.

## MEETINGS OF THE SECTIONS.

(Full accounts of all meetings should be sent to Secretary Charles L. Parsons,  
 1709 G St., N. W., Washington, D. C.)

## AMES SECTION.

At the regular meeting, held on February 24, the following addresses were given:  
 "The Distillation of Aqueous Solutions of Formaldehyde," by J. A. Wilkinson; and  
 "The Decomposition of Potassium Chlorate," by F. E. Brown.

H. L. MAXWELL, *Secretary*.

## CALIFORNIA SECTION.

The 121st regular meeting of the Section was held on February 18. The following program was given: "The Amino Carbonic Acids and Their Salts," by E. C. Franklin, of Stanford University; and "Production of Natural Potash Alum," by Lindsay Duncan, of San Francisco.

LYDD W. CHAPMAN, *Secretary*.

## CHICAGO SECTION.

On March 18, Lafayette B. Mendel, of Yale University, spoke before the members of the Chicago Section, on the subject: "What Constitutes a Food?"

S. L. REDMAN, *Secretary*.

## CINCINNATI SECTION.

The 241st regular meeting of the Section occurred on March 9, when H. W. Jordan, of the Somet-Solvay Company, spoke on "The Solvay Chemical Industries; Their Work in War and Peace."

CARL H. LUND, *Secretary*.

## COLORADO SECTION.

At the regular meeting of the Section, on February 28, R. G. Gustavson gave a paper on "Some Application of the Electron Theory to Chemistry."

RUTH B. VUTRUBBS, *Secretary*.

## CONNECTICUT VALLEY SECTION.

On March 18, Harry N. Holmes, of Oberlin College, spoke before the Section on "Gels and the Application of Colloidal Chemistry."

HARRY WISSELS, *Secretary*.

## CORNELL SECTION.

The regular meeting of the Section was held on February 28, when O. A. Johannsen addressed the members on "Poisonous Insects and the Poisons of Insects."

F. R. GEORGIA, *Secretary*.

## DELAWARE SECTION.

Marston T. Bogert, of Columbia University, addressed the members of the Section, March 23, on "Science and Disarmament."

FRED C. ZEISSBERG, *Secretary*.

## DETROIT SECTION.

The 123rd meeting of the Local Section was held on February 16. The address of the evening was by Carl Thieme, of the Michigan Smelting and Refining Co., who spoke on "The Physical Metallurgy of the Non-ferrous Metals."

The 124th meeting of the Section occurred on March 16, when F. O. Taylor, of Parke, Davis & Company, spoke on "The Vitamines."

WM. B. TEMPLETON, *Secretary*.

## GEORGIA SECTION.

The members of the Georgia Section were the guests of the Atlanta Chapter of the American Institute of Electrical Engineers, on February 25. The speaker, Charles G. Adsit, addressed the meeting on the subject of "Rainfall."

J. S. BROGDON, *Secretary*.

## INDIANA SECTION.

William J. Hale, of the Dow Chemical Company, Detroit, Mich., addressed the meeting of the Section on February 18, his subject being "The Immediate Needs of Chemistry in America." W. M. Blanchard, of DePauw University, spoke on "Chemistry in the Service of Medicine." Attendance, 31%.

On March 11, the members of the Section were addressed by Mungo E. Nasmith, superintendent of the Commercial Solvents Company, at Terre Haute, Ind., on the subject, "Butyl Alcohol and Acetone from Corn." Attendance, 32%.

EDGAR B. CARTER, *Secretary*.

## KANSAS CITY SECTION.

The regular February meeting of the Section was held in Lawrence, Kansas, on February 19, in a joint program with the 53rd annual meeting of the Kansas Academy of Science. There were presented during the sessions of the two organizations 46 papers on various scientific subjects.

LEE E. CLARK, *Secretary*.

## LEXINGTON SECTION.

The 68th meeting of the Section was held on February 25. A paper was read by C. A. Shull on "The Magnitude of Some Natural Forces." Attendance, 26%.

S. D. AVERITT, *Secretary*.

## LOUISIANA SECTION.

On February 18, Robert Glenk, Curator of the State Museum, presented a paper before the Section on "Louisiana Lignite," illustrated with lantern slides and specimens. At this meeting the following officers were elected for 1921: H. W. Moseley, *President*; C. L. Clay, *Vice-President*; H. R. Stevens, *Secretary*; F. W. Liepsner, member *Ex-Officio*; and Charles E. Coates, *Councilor*.

H. R. STEVENS, *Secretary*.

## LOUISVILLE SECTION.

At the regular monthly meeting of the Section, held on February 18, R. L. Beakes, of the Louisville Lead and Color Company, gave a talk on the subject of "Paints and Varnishes."

C. E. GEIGER, JR., *Secretary*.

## MICHIGAN AGRICULTURAL COLLEGE SECTION.

On January 19, at a luncheon given by the Section, a roll call was responded to by the names of eminent scientists and a brief statement of their best-known works given. Attendance, 50%.

D. T. Ewing spoke before the members on January 25 in the Kedzie Chemical Laboratory, his subject being "The Electrometric Titration of Oxidation and Reduction Reactions." Attendance, 75%.

At the regular meeting of the Section, held on February 9, C. E. Bement, of the Novo Engine Company, Lansing, Mich., spoke on the present industrial situation. Attendance, 50%.

C. S. ROBINSON, *Secretary*.

## MILWAUKEE SECTION.

On March 18, C. B. Dickey, of the Corona Chemical Company, addressed the Section on the subject of "Some Chemical Facts and Theories of Operative Photography."

O. A. CHERRY, *Secretary*.

## NASHVILLE SECTION.

The Section had as its speaker on March 7 George E. Marton, of The Barrett Company, whose subject was "The Chemistry and Methods of Wood Preservation," illustrated with lantern slides and moving picture films.

H. A. WEBB, *Secretary*.

## NEBRASKA SECTION.

At a special meeting of the Section, held on February 19, S. B. Arenson reported on "A New Quantitative Method for the Determination of Potassium in Potash Waters."

J. C. Russell, of the University of Nebraska, spoke before the Section, March 24, on "Acidity of Nebraska Soils."

SAUL B. ARENSEN, *Secretary*.

## NEW HAVEN SECTION.

At a meeting of the Section on March 1, R. Dawson Hall, editor of *Coal Age*, spoke on "The Coal Industry."

BLAIR SAXTON, *Secretary*.

## NEW YORK SECTION

On March 11, Frank G. Breyer, chief of the research division of the New Jersey Zinc Company, spoke before the meeting of the Section on "Paint and Rubber Pigments."

H. G. SIDEBOTTOM, *Secretary*.

## NORTHEASTERN SECTION.

The 165th regular meeting of the Section, held on March 11, had the following addresses: "Aluminum and Its Light Alloys," by Robert S. Williams; and "Modern Smokeless Powder," by Tenney L. Davis.

L. F. HAMILTON, *Secretary*.

## OKLAHOMA SECTION.

The mid-winter meeting of the Oklahoma Section was held on February 12 at the University of Oklahoma, Norman, Okla. The following program was carried out: "A Neglected Test for Morphine," by Guy Y. Williams; "Changes in the Composition of the Fat of Peanut-Fed Rabbits during Starvation," by C. T. Dowell; "Colloid Chemistry and Petroleum," by Fred A. Padgett; "Relations between Granular Electricity, Atomic Structure and Valence," by A. F. Reiter; "Metallic Soaps," by Hilton Ira Jones; "The Separation of Caffeine from Cocaine-Allied Alkaloids from Syrups Used in Soft Drinks," by Edwin DeBarr; and "The Manufacture of Alcohols and Other By-Products from Petroleum," by Sidney Born.

HILTON IRA JONES, *Secretary*.

## OREGON SECTION.

On February 26, at the regular monthly meeting of the Section, held at the Seward Hotel, Portland, Oregon, the following addresses were given: "The Western Beet Sugar Industry," by E. W. Lazell; and "Some of the Less Common Sugars," by H. R. Kelly.

The following officers have been elected to serve for 1921: Ralph K. Strong, chairman; H. G. Miller, vice-chairman; Page R. Boyles, Secretary-treasurer; and John F. Fulton, councilor.

At the regular meeting of the Section, held at Reed College, the following addresses were given: "Industrial Uses of City Gas," by E. L. Hall, General Superintendent of the Portland Gas and Coke Company; and "Combustible Gases, Their Characteristics and Recent Developments," by R. K. Strong, of Reed College.

PAGE R. BOYLES, *Secretary*.

## PHILADELPHIA SECTION.

The regular monthly meeting of the Section occurred on March 17, at the Engineers' Club, Philadelphia, when James F. Norris, of Massachusetts Institute of Technol-

ogy, spoke on "Recent Progress in Organic Chemistry." At the usual informal dinner, the address was given by William Martin, of Philadelphia, who spoke on "A Glimpse of the Traffic Man's Point of View."

J. HOWARD GRAHAM, *Secretary*.

#### PITTSBURGH SECTION.

The annual smoker of the Section was given on February 24 at the U. S. Bureau of Mines Building, Pittsburgh, Pa.

On March 17, E. M. Chamot, of Cornell University, addressed the Section on the subject of "Industrial Microscopy."

GERHARD STEGEMAN, *Secretary*.

#### PUGET SOUND SECTION.

The regular monthly meeting of the Section occurred on February 23, when George E. Whitwell, of the University of Washington, spoke on the subject: "Efficiency and Economy in the Manufacture, Distribution, and Utilization of Illuminating Gas."

R. W. ELLISON, *Secretary*.

#### ROCHESTER SECTION.

Dr. Edgar F. Smith, President of the American Chemical Society, addressed the members of the Rochester Section on the evening of February 21. An informal dinner in honor of Doctor Smith was served at the Rochester Club.

The 120th meeting of the Section occurred on March 7, at the University of Rochester, when Edward B. Leary, of the Leary Dye Works, discussed the subject of "Where and How the Chemist Helps in an Ordinary Business." His talk was illustrated by experiments and lantern slides.

ERLE M. BILLINGS, *Secretary*.

#### ST. LOUIS SECTION.

H. A. Carlton, of the Mallinckrodt Chemical Works, read a paper before the regular monthly meeting of the Section, March 7, on "Arsphenamine."

H. A. CARLTON, *Secretary*.

#### SAVANNAH SECTION.

The following papers were read before the members of the Local Section on March 3: "The Economic Position of Cottonseed Oil," by B. F. Taylor; and "By-Product Coke Ovens and the Manufacture of Ammonium Sulfate," by A. B. Carmichael. Attendance, 36.6%.

HERBERT P. STRACE, *Secretary*.

#### SOUTHERN CALIFORNIA SECTION.

Two connected lectures, on February 18 and 19, on the subject of "Structure of the Atom," were delivered by Robert A. Millikan, professor of physics, University of Chicago, before a joint meeting of the local sections of the American Chemical Society, American Institute of Electrical Engineers and the Mathematics and Science Association.

H. L. PAYNE, *Secretary*.

#### SOUTHEAST TEXAS SECTION

On March 19, the following program was given before the Section: "The Manufacture of Casing Head Gasoline," by Frank Seibert, of the Gulf Pipe Line Company; and "The Transportation of Oil," by Charles Fitzgerald, Jr., of the White Oil Company.

P. S. TILSON, *Secretary*.

#### SOUTH JERSEY SECTION.

The 6th regular meeting of the Section was held on February 16 at the du Pont Club. H. D. Gibbs spoke on "Palm Trees as a Commercial Source for Alcohol and Sugar." Attendance, 63%.

C. E. BURKE, *Secretary*.

#### SYRACUSE SECTION.

A meeting of the Section was held on February 11, when A. G. Carmen, of Syracuse, gave a lecture on "Principles and Practice of Die Castings." Attendance, 8½%.

The 147th meeting of the Section occurred on February 25, when James Kendall, of Columbia University, spoke on "A Modified Ionization Theory."

An extra winter meeting of the Section was held on March 4 in the Chamber of Commerce, in the form of a joint banquet with the Society of Steel Treathers; John A. Mathews, president of the Crucible Steel Company, speaking on the advances made by that company in the manufacture of high-grade steels for special purposes.

BYRON W. GRIMES, *Secretary*.

#### TOLEDO SECTION.

L. V. Redman, president of the Redmanol Chemical Products Company, of Chicago, spoke on "Synthetic Phenol Resins," at the regular monthly meeting of the Section, held on March 11.

R. W. ERWIN, *Secretary*.

#### UNIVERSITY OF ILLINOIS SECTION

At the regular meeting of the Section, held on March 15, Farrington Daniels, of the University of Wisconsin, spoke to the members on the subject of "The Radiation Hypothesis and Reaction Velocity."

S. A. BRALBY, *Secretary*.

#### UNIVERSITY OF MICHIGAN SECTION.

On March 1, A. E. White, of the University of Michigan, spoke before the Section on the subject: "The Constitution and Properties of Boiler Tubes."

C. C. MELOCHE, *Secretary*.

#### VIRGINIA SECTION.

The 41st meeting of the Section was held on March 18, when Hugh S. Taylor addressed the members on "Pure Research in the Development of Industrial Catalysis."

ROBERT F. MCCrackAN, *Secretary*.

#### WASHINGTON, D. C., SECTION.

The 315th meeting of the Section was held at the Cosmos Club on March 10, when the following addresses were given: "Chemical Crystallography," by E. T. Wherry; and "X-Ray and Crystal Structure," by R. W. G. Wyckoff.

J. B. REED, *Secretary*.

#### WISCONSIN SECTION.

At the regular monthly meeting of the Section, held on February 23, V. L. Bohnsen spoke on "Some Recent Researches on the Catalytic Decomposition of Hydrogen Peroxide."

On March 16, David Fahlberg, of the Department of Chemical Engineering, spoke before the members of the Section on "Some Micro-Chemical Studies of Steel."

V. L. BOHNSON, *Secretary*.

#### DECEASED.

Hinds, J. I. D., 1718 West End Ave., Nashville, Tenn., died March 4, 1921.

Kuzirian, Simon B., Box 87, Jamaica, L. I., died Feb. 5, 1921.

Olin, F. W., Jr., 1128 Saate St., Alton, Ill., died Feb. 4, 1921.

Ruffle, John, Musley Hill, Ware, Herts, England, died Nov. 19, 1920.

# Proceedings.

## Minutes of the Directors Meeting.

The Directors of the American Chemical Society met at Mechanics Institute, Rochester, April 27, 1921, at 3.00 p. m., with President Smith in the chair and the following Directors present: Bancroft, Bigelow, Little Rosengarten, Talbot, and Parsons.

The Council having unanimously voted

That this Council expresses to the Directors of the Society the hope that the Eschenbach Printing Company will be released from any forfeits that may arise under the terms of its contract in connection with the impending strike, due to the insistence upon the 44-hour week, and

That the members of this Council speaking for the members of their local sections also express their full willingness, in the event such a strike is not amicably settled, to wait indefinitely for the publication of the journals of the Society

and the Advisory Committee and several of the local sections of the American Chemical Society having also expressed their agreement with the above vote, the Directors unanimously voted to release the Eschenbach Printing Company from all forms of penalties or forfeits that might arise under the current terms of its contracts with the American Chemical Society in the event of a delay in the publication of the Society's journals incident to such strike, and they further voted that the Directors would agree to any temporary suspension of publication necessary.

It was voted to authorize the editors of the Society's journals to destroy any letter files and manuscript files over two years old no longer required, in their opinion, for the proper conduct of their offices.

The Directors voted to authorize the Treasurer to pay a bill of \$17.50 from Incidental Account incurred by the chairman of the Committee on Occupational Diseases.

The Treasurer announced the purchase of temporary securities as follows:

February 9, 1921, Two 90-day Bank of America Acceptances, due May 10, 1921, yielding  $6\frac{1}{8}\%$ . Cost \$13,962.93.

March 6, 1921, One City of Memphis 6% Tax Anticipation Note at 99.8802, due Sept. 1, 1921. Cost \$9,988.02.

March 24, 1921, Two City of Spartanburg 6% Tax Anticipation Notes, due August 19, 1921. Cost \$10,021.89.

This action received the approval of the Directors.

The Directors voted to authorize the Treasurer in case of necessary absence from his office to delegate the signing of routine and other necessary Society checks to a member of the Finance Committee as his attorney, "and that the Farmers' Loan & Trust Company be authorized to pay all checks when signed by a member of the Finance Committee, having previously been advised by the Treasurer of the appointment of such member as his attorney."

The Directors voted to authorize the Treasurer to open a separate account, entitled "American Chemical Society Account No. 2" in the Farmers' Loan & Trust Company, and to deposit therein checks drawn on his regular account covering a number of small items in one collective bill, such as Abstractors and Assistant Editors' checks, etc., and to cover the checks on his regular account by one voucher, as suggested by the auditors and outlined in his letter of April 25, 1921, to the Secretary of the

Society. They further voted to authorize him to delegate authority to sign checks on this special account, covering the numerous items included in the one voucher, to A. J. Marratt, his secretary, "and that the Farmers' Loan & Trust Company be authorized to pay any checks signed by A. J. Marratt, Attorney, on the account of the Society entitled American Chemical Society Account No. 2."

The Directors then adjourned.

CHARLES L. PARSONS, *Secretary*.

## COUNCIL.

President Edgar F. Smith has appointed Dr. George B. Frankforter to represent the American Chemical Society at the inauguration of Dr. Lotus Delta Coffman as President of the University of Minnesota, to be held on May 13, 1921.

Dr. Thomas G. Delbridge, of the Atlantic Refining Co., Philadelphia, Pa., at the request of President Smith, represented the Society as its delegate at a meeting held under the auspices of the American Petroleum Institute in New York City, April 11, to consider uniform testing methods, the ways and means of procuring their adoption by the oil industry, and the establishment of a method of arbitration in disputes over oil tests.

### MEMBERS ELECTED BETWEEN MARCH 15 AND APRIL 15, 1921.

Adams, James Edward, 222 Marsteller St., West Lafayette, Ind.  
 Aldridge, Alfred Edward, 22 Ngata St., Palmerston North, New Zealand.  
 Allen, Raymond P., Lima, N. Y.  
 Allison, A. E., B. Medberry Hobart College, Geneva, N. Y.  
 Anderson, Daved E., Augustana College, Rock Island, Ill.  
 Armstrong, Paul L., 284 Franklin Ave., River Forest, Ill.  
 Aydelotte, J. T., 207 Alberta Corner, Calgary, Alta., Canada.  
 Babcock, E. B., 428 N. Firestone Blvd., Akron, O.  
 Barthels, Herbert W., 41 Second St., National City, Calif.  
 Bassett, James W., 743 McMackin Ave., Winton Place, Cincinnati, O.  
 Berman, Harry, 116 Nonotuck St., Holyoke, Mass.  
 Birkner, Victor, 552 14th St., S. E., Washington, D. C.  
 Boley, Conrad H., 50 N. Aberdeen Place, Atlantic City, N. J.  
 Bowen, C. W., Brunswick, Mo.  
 Bradbeer, Chester B., 126 N. Hartwick, Eagle Rock City, Calif.  
 Brewer, Robert K., 706 Maryland Ave., Syracuse, N. Y.  
 Bruce, James, The Technical College, Huddersfield, England.  
 Burns, Kevin, Allegheny Observatory, Pittsburgh, Pa.  
 Caulkins, Asa L., 530 E. Walnut St., Stockton, Calif.  
 Cavanaugh, Geo. W., 217 Willard Way, Ithaca, N. Y.  
 Chen, Yu Gwan, 1116 Amsterdam Ave., New York City.  
 Cloke, John B., Hoosick, N. Y.  
 Council, Frank E., Texas Christian University, Forth Worth, Tex.  
 Craig, Paul S., Bowne Hall, Syracuse University, Syracuse, N. Y.  
 Curtis, Arthur James, 3277 W. 98th St., Cleveland, O.  
 Dalton, John N., 900 Hope St., Providence, R. I.  
 Dicks, Charles B., Jr., 34 Dana St., Cambridge, Mass.  
 Dunkle, Cyrus G., 1125 Hillsdale Ave., Dormont, Pa.  
 Durham, Hobart N., Suite 9, 84 St. Botolph St., Boston, 17, Mass.  
 Edlund, Karl R., 1233 3rd Ave., Oakland, Calif.  
 Everhart, W. Alfred, P. O. Box 564, Granville, O.  
 Fischer, Arthur H., 223 Ohio Ave., Providence, R. I.  
 Flett, Raymond L., 325 W. 3rd St., Cincinnati, O.  
 Fowlkes, Floyd E., John Marshall High School, Richmond, Va.  
 Friedman, Joseph S., National Aniline & Chemical Co., Buffalo, N. Y.  
 Gilfillan, F. A., 954 Yale Station, New Haven, Conn.  
 Hall, Sydney H., 59 Cheriton Road, Wollaston, Mass.  
 Harrison, George F., 260 Olney St., Providence, R. I.  
 Havighurst, R. J., 130 N. Washington St., Delaware, O.

Quaker City Rubber Company, Wissinoming, Philadelphia, Pa.

## MEETINGS OF THE SECTIONS.

(Full accounts of all meetings should be sent to Secretary Charles L. Parsons, 1709 G St., N. W., Washington, D. C.)

#### CALIFORNIA SECTION.

The 122nd regular meeting of the Section was held on March 18 at the San Francisco Commercial Club, when the following program was given: "The Present Status of Chemical Criteria in the Field of Soil Fertility," by John S. Burd, of the University of California; and "Experimentation at the Temperature of Liquid Hydrogen," by Wendell M. Latimer, of the University of California. LLOYD W. CHAPMAN, *Secretary*.

#### CINCINNATI SECTION.

The 242nd regular meeting of the Section occurred on April 11, at the University of Cincinnati. J. Howard Mathews, chairman of the Chemistry Department, University of Wisconsin, gave an illustrated lecture on "Color Photography."

CARL H. LUND, *Secretary*.

#### COLUMBUS SECTION.

On April 16, the Section had as its speaker, J. Howard Mathews, of the University of Wisconsin, who spoke on "Photo-Chemistry."

MARION HOLLINGSWORTH, *Secretary*.

## CORNELL SECTION.

V. A. Moore, dean of the New York State Veterinary College, spoke before the Section, March 29, on "Chemical Problems in Immunity." F. R. GEORGIA, *Secretary*.

## DETROIT SECTION.

The 124th meeting of the Section was held on April 15, when J. Howard Mathews spoke before the members on "Photo-Chemistry." WM. B. TEMPLETON, *Secretary*.

## EASTERN NEW YORK SECTION.

C. B. Welter, of the General Electric Co., addressed the members of the Section, March 17, on the subject of "X-Rays in Medical Diagnosis."

On April 8, Matthew A. Hunter, of the Rensselaer Polytechnic Institute, spoke before the Section on "Some Electrical Properties of Alloys."

MARY R. ANDREWS, *Secretary*.

## INDIANA SECTION.

The Indiana Section held its regular monthly meeting on April 8, when E. W. McCullough spoke on "Flotation." Attendance, 23%. EDGAR B. CARTER, *Secretary*.

## LEHIGH VALLEY SECTION.

On April 1, Edgar F. Smith, President of the American Chemical Society, addressed the members of the Section on "Early Organic Chemistry in America." Attendance, 55%.

At the business meeting held on this date the following officers were elected: John T. Little, *Vice-Chairman*; E. C. Bingham, *Senior Councilor*, and R. N. Boyd, *Junior Councilor*. Resolutions adopted by the University of Illinois Section, dated November, 16, 1920, were ordered placed on file and no action to be taken at this time. Resolutions favoring the adoption of the metric system were favorably reported and will be presented at the Rochester meeting. A membership committee was appointed to take charge of a campaign to solicit new members for the Society. J. G. SKULL, *Secretary*.

## LEXINGTON SECTION.

The 69th meeting of the Section was held at the University of Kentucky, on March 23, when O. J. Stewart spoke on "The Technique of Atomic Weight Determinations by the Silver Method." Attendance, 44%.

S. D. AVERITT, *Secretary*.

## LOUISIANA SECTION.

The 135th regular meeting of the Section occurred on March 18, when two papers were presented by S. A. Mahood, of Tulane University, as follows: "The production of American Storax from the Red Gum Tree" (illustrated); and "Comparison of Wood Cellulose and Cotton Cellulose."

The 136th meeting of the Section was held on April 15. Harry B. Weiser, of Rice Institute, Houston, Tex., addressed the members on the subject of "Colloidal Chemistry."

H. R. STEVENS, *Secretary*.

## MICHIGAN AGRICULTURAL COLLEGE SECTION.

On April 14, J. Howard Mathews, of the University of Wisconsin, spoke before the members on the subject, "Photo-Chemistry."

C. S. ROBINSON, *Secretary*.

## MIDLAND SECTION.

At the regular monthly meeting of the Section, held on April 13, J. Howard Mathews addressed the members on "Photo-Chemistry."

C. C. KENNEDY, *Secretary*.

## NASHVILLE SECTION.

On March 18, a phosphate symposium was held by the Section, when the following speakers addressed the members of the Section: Lucius P. Brown, former State Food and Drug Commissioner of Tennessee; James A. Barr, chief engineer, International Agricultural Corporation, Mount Pleasant, Tenn., and Wm. R. Austin, chief chemist, Tennessee Chemical Co., Nashville, Tenn.

H. A. WEBB, *Secretary*.

## NEW HAVEN SECTION.

The regular monthly meeting of the Section occurred on March 31, in Kent Chemical Laboratory. Hugh S. Taylor, of Princeton, spoke on "Scientific Research and the Development of Industrial Catalytic Processes."

On April 25, C. H. Mathewson addressed the members on the subject, "Rolled Zinc."

BLAIR SAXTON, *Secretary*.

## NORTHEASTERN SECTION.

The 166th regular meeting of the Section occurred on April 8, at the Engineers' Club, Boston, Mass. The following program was given: "Publicity," by J. W. Harrington, technical manager of the American Chemical Society News Service; "Some Chemical Problems Connected with the Vat Dyes," by James B. Conant, of Harvard University; and "The Enamelling of Sheet Steel," by Earle P. Stevenson, of Arthur D. Little, Inc.

L. F. HAMILTON, *Secretary*.

## PHILADELPHIA SECTION.

On April 21, the following program was given by the Section: "Recent Developments of the Work of the Bureau of Standards," by W. C. Wagner, assistant to chief engineer, Philadelphia Electric Company; "Refractometry," by Warren P. Valentine. The after-dinner address was given by Richard Spillane, financial editor of the Public Ledger, who spoke on "How to Reach our Friends, the Public."

J. HOWARD GRAHAM, *Secretary*.

## PITTSBURGH SECTION.

R. F. Bacon, of the Mellon Institute, spoke before the Section on April 21, his subject being "Technology of the American Sulphur Industry."

GEBHARD STEGEMAN, *Secretary*.

## PUGET SOUND SECTION.

At the regular monthly meeting of the Section, held on March 23, Mrs. Zahlia Jencks Gailey, spoke on "Some Chemical Aspects of Electro-Plating."

R. W. ELLISON, *Secretary*.

## RHODE ISLAND SECTION.

On March 18, an illustrated lecture was given before the Section by J. C. Olsen, of the Brooklyn Polytechnic Institute, his subject being "The Manufacture of Starch Glucose and Dextrine from Corn."

HERBERT F. DAVISON, *Secretary*.

## ROCHESTER SECTION.

The 121st regular meeting of the Section was held on March 21. C. E. Kenneth Mees gave an illustrated lecture on "Measuring Stars by Light Waves."

The 122nd regular meeting occurred on April 4, when Donald W. Howe, chief chemist, Beechnut Packing Co., spoke on "Foods and Science."

On April 18, Carl L. Alsberg, formerly chief chemist of the Bureau of Chemistry, Department of Agriculture, Washington, D. C., addressed the members on the subject, "Has the Federal Government a Policy in Science and Research?"

ERLE M. BILLINGS, *Secretary*.

## ST. LOUIS SECTION.

At the regular monthly meeting of the Section, held on April 4, the following program was given: "The Distillation of Missouri Oaks, by K. K. Kershner; and "The Preparation and Properties of Furfural and Some of the Derivatives of Furfural," by M. S. Badollet and H. L. Dunlap.

H. A. CARLTON, *Secretary*.

## SOUTHERN CALIFORNIA SECTION.

The regular monthly meeting of the Section occurred on March 31, when Frederick Bulpitt, director in charge of the Metabolic Research Clinic Laboratory of the White Memorial Hospital, spoke on the subject, "The Chemical Examination of the Blood."

H. L. PAYNE, *Secretary*.

## SOUTH JERSEY SECTION.

The 7th regular meeting of the Section was held on March 24. Roger Williams spoke on "Conducting Research."

C. E. BURKE, *Secretary*.

## SYRACUSE SECTION.

The 149th meeting of the Section occurred on March 25, when William H. Walker, of Boston, Mass., spoke on "Research Methods."

B. W. GRIMES, *Secretary*.

## TOLEDO SECTION.

On March 23, P. E. Landolt, of New York City, manager of the Commercial Department of the Research Corporation, gave a lecture on "Cottrell Electrical Precipitation," illustrated with slides and motion pictures. Attendance, 84.

J. Howard Mathews, of the University of Wisconsin, addressed the members of the Toledo Section, April 12, on "Color Photography."

## UNIVERSITY OF MICHIGAN SECTION.

At the regular meeting of the Section, held on March 29, D. M. Lichty spoke before the members on the subject, "The Action of the Insoluble Oxides, Hydroxides and Carbonates on Ammonium Chloride."

C. C. MELOCHE, *Secretary*.

## VIRGINIA SECTION.

The 42nd meeting of the Section occurred on April 15. Graham Edgar addressed the members on "Chemical Combination and the Nature of Valence."

ROBERT F. MCCracken, *Secretary*.

## WASHINGTON, D. C., SECTION.

The 317th meeting of the Section was held on March 25, the following lectures being given: "Chemical Industry from the Tariff Standpoint," by C. R. DeLong; and "The Tariff on Certain Minerals used in Chemical Industries," by F. L. Hess.

The 318th meeting of the Section, held on April 14, had as its speaker, Dr. Edgar F. Smith, President of the American Chemical Society, who spoke on "A Glance at the Early Organic Chemistry of the United States."

J. B. READ, *Secretary*.

## WISCONSIN SECTION.

On March 23, E. D. Fahlberg, of the Department of Chemical Engineering, University of Wisconsin, spoke before the Section on "The Chemical Macroscopy of Metals."

V. L. BOHNSON, *Secretary*.

## DECEASED.

Hasslacher, Jacob, 709 Sixth Ave., New York, N. Y.

Pennock, J. D., Solvay Process Co., Syracuse, N. Y.

# Proceedings.

## GENERAL MEETING MINUTES.

The 61st general meeting of the American Chemical Society was held at Rochester N. Y., Monday, April 25, to Friday, April 29, 1921, inclusive. The Council meeting was held on the 25th, the general meeting on the morning and afternoon of the 26th, divisional meetings all day Wednesday and Thursday, and excursions on Friday. Full details of the meeting and program will be found in the May issue of the *Journal of Industrial and Engineering Chemistry*. The registration was 1139, and 1270 sat down to dinner at the Good Fellowship Meeting.

General public addresses were given by Senator James W. Wadsworth, Jr., on "Some Problems of National Defense," and by Congressman Nicholas Longworth, on "The American Chemical Industry and Its Need for Encouragement and Protection." At the general business meeting held Tuesday morning, April 26th, Charles F. Chandler and William H. Nichols were unanimously elected Honorary Members of the Society. The chief public address was given at Convention Hall on Wednesday evening, April 27th, by Charles F. Chandler, on "Chemistry in the United States." At the general meeting on Tuesday afternoon, the following general papers were presented:

General Meeting, Convention Hall, Clinton Avenue South.

E. C. Franklin, "Ammono Carbonic Acids."

C. E. K. Mees, "The Measurement of Color." (Illustrated.)

W. D. Bancroft, "Blue Eyes and Blue Feathers." (Illustrated.)

R. E. Wilson, "Surface Films as Plastic Solids,"

Irving Langmuir, "The Relation between the Stability and the Structure of Molecules."

G. N. Lewis, "Ionization of Electrolytes."

The following Divisions and Sections met: Divisions of Agricultural and Food Chemistry, Biological Chemistry, Dye Chemistry, Chemistry of Medicinal Products, Industrial and Engineering Chemistry, Organic Chemistry, Physical & Inorganic Chemistry, Rubber Chemistry and Water, Sewage and Sanitation; Sections of Cellulose Chemistry, Petroleum Chemistry, and Sugar Chemistry and Technology. Further details of their meetings will be found in the May issue of the *Journal of Industrial and Engineering Chemistry*.

Tuesday evening was given up to dinners and gatherings of various colleges and fraternities. Thursday evening the Good Fellowship Meeting, complimentary to the members by the Rochester Section, consisted of a dinner in the Bausch and Lomb dining hall, followed by a varied and interesting program consisting of music, vaudeville entertainment, motion pictures of the convention itself and prominent members thereof, and a film shown for the first time, picturing the operations of the Eastman Kodak Company. The scientific program was the most extensive ever presented before a meeting of the American Chemical Society and consisted of 280 papers.

CHARLES L. PARSONS, *Secretary*.

## ADVISORY COMMITTEE MINUTES.

The Advisory Committee met at the Hotel Rochester, Rochester, N. Y., Monday, April 25, at 1.30 o'clock, with President Smith and Messrs. Herty, Howe, Lamb, Rosen-garten and Parsons present.

The Committee unanimously voted that in their opinion the Eschenbach Printing Company should be relieved from any penalties incident to a threatened strike of their printers and that the matter be brought before the Council with the recommendation that a similar vote be passed.

It was voted that it was not expedient to send further delegates to the National Trade Council as the Society was not a trade organization.

The question of delegates to the Brussels meeting of the International Union of Pure and Applied Chemistry was discussed and the matter was left to the National Research Council with certain suggestions of members who might be available in Europe at the time.

The Advisory Committee recommended that President Smith nominate E. C. Franklin, John Johnston, and John E. Teeple to succeed themselves in the Division of Chemistry and Chemical Technology of the National Research Council. This was done by President Smith.

The Committee recommended to the President that G. A. Richter be appointed to succeed R. C. Tolman, resigned, on the Committee to Cooperate with the Chemical Warfare Service. This also President Smith approved.

The Advisory Committee voted to recommend to the Council that we reaffirm opposition to the Nolan Patent Bill and the removal of the Federal Trade Commission "rider" therefrom, but that the Society declined to take any position on the so-called Federal Trade Commission "rider" if presented as a separate bill.

The Advisory Committee, after carefully considering the charges against Mr. Charles Bramson and the evidence presented, unanimously recommended that he be expelled from the Society for knowingly and willingly helping to distribute propaganda for the overthrow of our government by force.

CHARLES L. PARSONS, *Secretary*.

## COUNCIL MINUTES.

The Council of the American Chemical Society met at the Hotel Rochester, Rochester, New York, at 4 P. M., Monday, April 25, 1921, with President Edgar F. Smith in the Chair and the following Councilors present:

*Ex-Officio*.—W. D. Bancroft, W. D. Bigelow, E. J. Crane, A. W. Dox, Charles H. Herty, W. F. Hillebrand, John Johnston, Arthur B. Lamb, A. D. Little, Charles L. Parsons, Edgar F. Smith, H. F. Talbot.

*Councilors-at-Large*.—C. L. Alsberg, Edward C. Franklin, Bernhard C. Hesse, H. E. Howe, L. W. Jones, Irving Langmuir, William McPherson, George D. Rosengarten.

*Local Sections*.—*Ames*, W. F. Coover (subs. for J. A. Williamson). *California*, Ralph A. Gould. *Chicago*, D. K. French (subs. for W. R. Smith), W. Lee Lewis (subs. for Julius Stieglitz), Herbert N. McCoy, G. A. Menge (subs. for L. M. Tolman), A. V. H. Mory (subs. for C. S. Miner), L. V. Redman, S. L. Redman (subs. for A. M. Taylor), W. D. Richardson, Gerald L. Wendt (subs. for T. J. Bryan), Frank C. Whitmore (subs. for R. J. Quinn). *Cincinnati*, Hugh M. Campbell (subs. for M. B. Graff), A. B. Davis, C. P. Long, A. P. Mathews. *Cleveland*, O. F. Tower, A. W. Smith. *Colorado*, W. Engle (subs. for S. J. Osborn). *Columbus*, H. D. Higley. *Connecticut Valley*, Jos. S. Chamberlain, C. R. Hoover. *Cornell*, A. W. Browne. *Delaware*, Hamilton Bradshaw, P. B. Holmes (subs. for Charles L. Reese), Roger Williams (subs. for George Norman). *Eastern New York*, E. H. Darby (subs. for Edward Ellery). *Indiana*, F. C. Atkinson, Frank R. Eldred, Edward G. Mahin. *Iowa*, Edward Bartow. *Kansas City*, F. B. Dains. *Lehigh Valley*, Eugene C. Bingham. *Louisiana*, C. E. Coates. *Midland*, William J. Hale. *Minnesota*, A. D. Hirschfelder (subs. for E. P. Harding). *Nebraska*, Fred W. Upson. *New Haven*, Harold Hibbert (subs. for W. R. Hibbard). *New York*, Charles Baskerville, C. A. Browne, Robert P. Fischelis (subs. for F. J. Metzger), Irving Fellner (subs. for J. R. M. Klotz), Ellwood Hendrick, Martin H. Ittner, James Kendall, A. C. Langmuir, K. G. Mackenzie, Ralph H. McKee, R. R. Renshaw (subs. for F. E. Dodge), Charles F. Roth, Wallace Savage (subs. for Ralph G. Wright), H. G. Sidebottom (subs. for D. W. Jayne), B. R. Tunison, John B. Tuttle (subs. for V. C. Edwards), David Wesson. *Northeastern*, George L. Coyle, Winthrop

C. Durfee, George S. Forbes, William A. Kingman (subs. for Robert S. Weston), Robert W. Neff (subs. for W. L. Jennings), James F. Norris, Wm. K. Robbins, Robert E. Wilson (subs. for W. K. Lewis). *Oregon*, O. F. Stafford (subs. for John Fulton). *Philadelphia*, G. E. Barton, A. M. Comey, J. S. Goldbaum, E. H. Grafton (subs. for W. C. Carnell), Walter T. Taggart, James G. Vail. *Pittsburgh*, Alexander Silverman, H. C. P. Weber (subs. for J. O. Handy). *Puget Sound*, Harlan L. Trumbull (subs. for H. K. Benson). *Rochester*, H. T. Clark, Harry LeB. Gray. *South Jersey*, H. Gibbs (subs. for Wm. Kirk). *St. Louis*, Charles E. Caspari, E. Mallinckrodt, Jr., E. J. Sheppard (subs. for L. McMaster). *University of Illinois*, Roger Adams, E. W. Washburn. *University of Michigan*, H. H. Willard. *Virginia*, W. F. Rudd. *Washington, D. C.*, W. D. Collins, R. C. Cook (subs. for W. M. Clark), J. B. Read (subs. for R. B. Sosman), Atherton Seidell, L. I. Shaw (subs. for F. W. Smither). *Western New York*, C. G. Derick, Walter Wallace, A. M. Williamson. *Wisconsin*, Victor Lenher, J. H. Mathews.

The Secretary announced the death of Professor Albert C. Hale, former Secretary of the American Chemical Society, and of Professor J. I. D. Hinds, for many years a Councilor of the Society. The Council rose and stood in silent tribute, and a vote was passed that resolutions be prepared and spread upon the Society minutes in tribute to these members.

The resolutions follow:

"WHEREAS: In the death of Doctor Albert C. Hale, of Brooklyn, N. Y., on April 24, 1921, the members of the American Chemical Society recognize the loss of a valued member and associate;

"Therefore, Be It Resolved:

"1. That as a member of the Society for forty-one years and as an earnest worker in all that related to its success during the period of his active life he will always be held in kindly remembrance.

"2. That the profession of Chemistry has lost in Doctor Hale a representative of high character and standing and especially in his chosen sphere of teaching, to which his whole life was devoted, a worker of distinction.

"3. That in the office of Secretary of the American Chemical Society, which he filled from 1889 to 1903, a critical period in the reorganization and growth of the Society, his services in respect to the two vital features of reorganization, namely: General Meetings and Local Sections, for which he acted as an organizer and general director in matter of detail, his enthusiastic labors and persistence were, in large measure, the secret of success, and that his name is imperishably linked in the history of the Society with these two features.

"4. That the sympathy of the Society is respectfully tendered to the family of Doctor Hale and that a copy of these Resolutions be sent to them by the Secretary."

"WHEREAS: In the death of Professor J. I. D. Hinds, of Nashville, Tenn., on March 4, 1921, the American Chemical Society recognizes the loss of one of its most valued members who has been a member of the Society for thirty years, a member of its Council for twenty years, an inspiring teacher for nearly fifty years, a useful citizen, a delightful friend, and a gentleman of learning and refinement,

"Therefore, Be It Resolved that the American Chemical Society wishes publicly to express its sincere sorrow on the loss of so valued a member and instructs its Secretary to transmit to the wife and daughter of Dr. Hinds, our sincere sympathy and to inform them that we, too, share in their loss."

Doctor George D. Rosengarten was elected to succeed himself for a period of two years as a member of the Committee on National Policy.

It was voted that the Society accept the invitation of the Alabama Section of the American Chemical Society to hold its spring meeting for 1922 in Birmingham, the time of the meeting to be determined by the Advisory Committee.

Doctor E. W. Washburn spoke briefly to the Council regarding the Annual Tables of Constants, informing them that Volume 4 could now be ordered from the Chicago University Press, Chicago, Ill., as published in the *Journal of the American Chemical Society*, and urging the support of individuals therefor.

Charles Bramson, of Joliet, Illinois, having been definitely charged with having taken part willingly and knowingly in the distribution of propaganda issued by the United Communist Party, recommending, among other things, the overthrow of our government by force, and all requirements of the Constitution having been duly met, evidence being presented and Mr. Bramson having been given an opportunity to reply thereto, was, by unanimous vote, expelled from membership in the American Chemical Society.

A petition signed by C. L. Alsberg, W. D. Bancroft, W. D. Bigelow, C. H. Herty, W. F. Hillebrand, A. B. Lamb, R. B. Moore, C. E. Munroe, C. L. Parsons, G. D. Rosengarten, and Edgar F. Smith, recommending for Honorary Membership in the American Chemical Society Charles F. Chandler and William H. Nichols, was presented to the Council. The Council unanimously recommended to the General Society their election as Honorary Members, and, as required by the Constitution, this recommendation was signed by a majority of the Council.

In regard to a communication from Edward Ellery, of the Eastern New York Section of the American Chemical Society, recommending that the Council pass resolutions favoring more universal teaching of the German language in our schools and colleges, the Council felt that so long as the technical state of war existed between this country and Germany it would be better to take no action, although realizing fully the importance of the German language to chemists.

H. E. Howe, representing Julius Stieglitz on the International Commission on Critical Tables of Physical and Chemical Constants, reported that 50% of the proposed budget had been raised and that rapid progress was being made.

The Council voted:

That this Council expresses to the Directors of the Society the hope that the Eschenbach Printing Company will be released from any forfeits that may arise under the terms of its contract in connection with the impending strike, due to the insistence upon the 44-hour week, and

That the members of this Council also express their full willingness, in the event such a strike is not amicably settled, to await indefinitely for the publication of the journals of the Society.

The Council voted that the Advisory Committee, on behalf of the American Chemical Society, select the two names to be presented to the Perkin Medal Committee as the American Chemical Society's candidates for the Perkin Medal.

A section of the American Chemical Society to be known as the Arkansas Section was established by the Council, with territory covering the State of Arkansas and with headquarters at Fayetteville, Arkansas, on petition signed by twenty-one members of the Society in good standing in that State.

The Secretary presented a communication to the Council from Raymond F. Bacon, Director of the Mellon Institute, calling attention to the very difficult situation existing throughout the country, not only in the national, but in the state legislatures, regarding the industrial alcohol situation, and particularly alcohol used in the flavoring extract, pharmaceutical and chemical industries. He presented the case as serious, much of the legislation quite unwillingly and apparently unknowingly bringing such hardships to bear upon these industries as to destroy them if enforced. The whole difficulty is due to ignorance on the part of the people presenting the laws, as they are not in a position to

differentiate adequately and intelligently between beverage alcohol preparations and alcohol for necessary manufacturing purposes.

The Council voted that the President should appoint a Committee on Industrial Alcohol to represent the Society in this matter and to formulate resolutions to be presented by them to the National and the State Legislatures concerned, in order to insure action which will protect the legitimate industries using alcohol and to properly distinguish between prohibition enforcements and the regulation of alcohol for industrial purposes.

It was further voted that any resolutions or recommendations of this kind which they may propose, when unanimously approved by the Committee on National Policy, shall become the action of the American Chemical Society.

The Council also asked Dr. Bacon to present the matter before the General Meeting on Tuesday morning, April 26th, which was done.

The President appointed Martin H. Ittner, Chairman, R. F. Bacon, Chas. Baskerville, F. R. Eldred, Edward Mallinckrodt, Jr., Geo. D. Rosengarten, and B. R. Tunison as the Committee.

The following resolutions were later adopted, and, being unanimously approved by the Advisory Committee, have, by the above vote of the Council, become the action of the American Chemical Society:

WHEREAS, the use of alcohol in many important industries is absolutely necessary not only to the continuance of such industries, but also for the manufacture of articles needed by other industries and even for the production of articles necessary to the protection of and sustenance of life itself, and

WHEREAS, it is the policy expressed in the National Prohibition Act to encourage the use of industrial alcohol for non-beverage purposes, such as the manufacture of thousands of necessary medicinals and countless dyes, chemicals, and perfumes and for the production of heat, light and power,

*Be It Resolved*, that the American Chemical Society advises and most strongly urges for the national welfare that all legislation for the enforcement of prohibition be so clearly drawn as not to restrict the activities of legitimate industries which must have industrial alcohol, and that all such legislation be so drawn as to provide in specific sections for the encouragement of the proper use of alcohol in the industries.

The following amendment to Article XI of the Constitution of the American Chemical Society was proposed to take effect beginning with the financial year of 1921.

Article XI shall be amended to read:

Section 1. The apportionment of funds to Local Sections shall be upon a sliding scale based upon their total paid membership of the year preceding, as follows:

Sections having less than 50 members, not exceeding \$2.25 per member; provided that a minimum of \$75.00 be allowed any Section.

Sections having not less than 50 members nor more than 125, not exceeding \$2.00 per member.

Sections having not less than 125 members nor more than 200, not exceeding \$1.50 per member.

Any Section having 200 or more members, not exceeding \$1.25 per member.

Provided that any Section may claim, etc.

Signed by: A. M. Comey, G. E. Barton, D. K. French, Harry LeB. Gray, James F. Norris, C. G. Derick, William J. Hale, L. I. Shaw, A. Silverman and Wm. W. Wallace, Members of the Council.

As required by the Constitution, a Committee of three was appointed by the President to which this amendment was referred. The Committee is as follows: H. E. Howe, Chairman, H. LeB. Gray, and A. V. H. Mory.

The Council unanimously voted its hearty thanks and appreciation to the Chairmen and members of the local committees of the Rochester Section and to the many in-

dividuals, firms and institutions in Rochester who contributed so bountifully to the success of the meeting.

The following resolution was presented and was unanimously passed by the Council:

WHEREAS, it appears probable that the Congress will speedily enact legislation terminating the state of war, and

WHEREAS, the power of the War Trade Board to control importations of coal-tar chemicals under the Trading-with-the-enemy Act automatically expires with the proclamation of peace, and

WHEREAS, we feel that the need of continued control of such importations from whatever source is urgent,

*Therefore Be It Resolved:*

First, that the Council of the American Chemical Society, representative of a nation-wide membership of fifteen thousand chemists, urge upon both the Senate and the House of Representatives the passage of ad interim legislation which will fully safeguard this industry until the Congress has adopted permanent protective legislation.

Second, that this resolution be telegraphed to the Chairman of the Finance Committee of the Senate and to the chairman of the Ways and Means Committee of the House of Representatives.

Telegrams were sent to the Chairman of the Finance Committee of the Senate and to the Chairman of the Ways and Means Committee of the House of Representatives.

A luncheon to be given to Mme. Curie in New York City on May 15th at the Hotel Waldorf was announced, and the attendance of members was urged.

The Committee appointed by the Council at Chicago to arrange for a longer time for the reading of scientific papers at general meetings reported that they recommended not less than four half days be devoted to divisional meetings at the general meetings of the Society. This recommendation was adopted.

The following resolution was presented and unanimously adopted:

WHEREAS, special knowledge is required in examining chemical patents and in making searches relating thereto, therefore be it

*Resolved:* that the Secretary of the American Chemical Society be authorized to call the attention of the Commissioner of Patents to the facts and recommend to him that a chemically trained examiner be appointed upon his staff of chief examiners.

The following resolution was presented and unanimously adopted:

*Resolved:*

The Secretary of each Division and Section of the Society is hereby authorized to demand submittal in advance of any paper offered for the program of a General Meeting, for decision as to its suitability for presentation at a General Meeting. The chairman and secretary of each Division and Section, acting jointly, are hereby authorized to decline acceptance of any paper, if in their judgment the circumstances warrant such action.

The Secretary presented to the Council a statement of the effect the change of dues had on the membership, showing that to date the Society was approximately nine hundred paid members behind the corresponding date of last year, but that the reason for this drop-off was unquestionably also due to the industrial depression as well as to the increase of dues. Of the fifteen thousand members, up to the present time one thousand one hundred and seventeen have availed themselves of the 33 1/3% discount as being registered undergraduate or post-graduate students in chemistry in some educational institution.

Mr. T. G. Delbridge, delegate of the Society to the meeting of the American Petroleum Institute in New York on April 17th, presented a report, which will be found printed in the May issue of the *Journal of Industrial and Engineering Chemistry*.

*The Committee to Coöperate with the Chemical Warfare Service* reported and its report will be found in the May issue of the *Journal of Industrial and Engineering Chemistry*.

*The Committee on Coöperation between Industries and Universities* reported progress and suggested the appointment of an entirely new committee which should be smaller in number but relatively larger representation from the industries.

*The Endowment Committee* reported that owing to the economic conditions the Committee had made no attempt to secure contributions or pledges to the endowment fund of the Society.

*The Committee on Exchanges* reported that the Society has now 355 exchanges; that during the year 69 new exchanges had been arranged, 11 old exchanges interrupted for one reason or another had been resumed, 4 exchanges discontinued, 7 offers to exchange refused. A list of new exchanges accompanied their list.

*The Committee on Guaranteed Reagents and Standard Apparatus* made an interesting report, which will be found printed in the May issue of the *Journal of Industrial and Engineering Chemistry*.

It was voted, in order to expedite the work of the Committee in case they make reports between meetings of the Council, that the Advisory Committee be empowered, when unanimous, to adopt the report, and when it be adopted that it be considered as the action of this Council.

*The Committee on Institute for Drug Research* presented a report which will be found printed in the May issue of the *Journal of Industrial and Engineering Chemistry*.

*The Insulation Committee (to Coöperate with Engineering Division, National Research Council)* reported progress.

*The Committee on International Normal Weight for Saccharimetric Sugar Solutions* reported that it appeared to be impossible to hope for the adoption of an international normal weight until international relationships became more settled.

*The Membership Committee* reported that during the year 2,289 individual members had been elected, also 75 corporate members and two life members; that 625 members had been dropped for delinquency, 591 had resigned, 53 had died, and that the total membership on December 31, 1920, was 15,582.

*The Metric System Committee to Coöperate with the American Metric Association, World Trade Club, London and Manchester Metric Associations* presented its report, which was discussed at some length and slightly modified. The modified report, as adopted by the Council, will be found in the May issue of the *Journal of Industrial and Engineering Chemistry*.

*The Committee on Morris Loeb Museum* reported as follows:

Your committee has been informed that such portion of the income of the Loeb bequest as is available for expenditure was turned over to the Smithsonian Institution in December last. The matter of the transfer of other property purchased by the Loeb funds consisting of one storage case, storage receptacles, a museum case, index cards and other stationery was taken up jointly by your committee and the officials of the Smithsonian Institution with the Chemists' Club in New York City with a view to having it transported to the Smithsonian Institution in Washington. Only a part of this material has been shipped to the Smithsonian Institution, the storage case at the date of writing not yet having been received. Until all this property is in the hands of the Smithsonian Institution, that Institution is not in position to take care of the materials collected without expending any of the fund for fresh storage cases and there was little occasion for your committee to function. Plans for building up the museum and for taking care of the material have been made in a tentative way. It is hoped the transfer of the property may soon be completed when your committee, if continued, will actively coöperate with the Smithsonian Institution in building up the museum.

C. L. ALSBERG, *Chairman*.

*The Committee on Nomenclature, Spelling and Pronunciation* reported as follows:

Work towards the standardization of chemical nomenclature and spelling in this country and Great Britain has progressed slowly during the past year. Tentative rules covering the more important points have been agreed upon and submitted to the corresponding committee of the London Chemical Society and to that of the Society of Chemical Industry. The latter committee has not thus far sent word of any action but the former committee has written us that it is in substantial agreement with the rules approved by our committee. A few minor changes were suggested and are under consideration.

The chairman of your committee receives rather frequent requests for information regarding points of nomenclature and spelling and gives such advice as he is able to send, pending the adoption of official rules. It is not practicable for your committee, which is a large one, to consider separately every little inquiry which is received. It is the purpose first to establish general principles and to consider only the more important specific points. I am careful to make it clear that advice offered from our experience in connection with *Chemical Abstracts* is not an official opinion of the committee. It seems best to try to help as much as we can even in an unofficial way.

Efforts are being made, particularly by the E. I. du Pont de Nemours & Co., to improve chemical nomenclature in trade usage. A discussion of this was published in the *Journal of Industrial and Engineering Chemistry*, 12, 1026. Your committee, through its chairman, has coöperated in this movement by conference and correspondence.

The chairman is also coöperating in the work of the Sub-Committee on Nomenclature of the U. S. Pharmacopeia Revision Committee, an appointment to which sub-committee he has accepted.

Respectfully submitted,

E. J. CRANE, Chairman.

*The Committee on Occupational Diseases in Chemical Trades* made an interesting and extensive report, which will be found printed in the May issue of the *Journal of Industrial and Engineering Chemistry*.

*The Paper Committee* reported that the quality of the present paper of the journals was far below the pre-war standard and recommended that as soon as possible the paper be brought back to the regular standard paper of the Society.

*The Patent and Related Legislation Committee* reported as follows:

The Patent and Related Legislation Committee begs to submit the following annual report:

During the past year your Committee has very actively continued its efforts to aid in securing the enactment of legislation for the relief of the Patent Office and to make certain beneficial changes in the Patent Statute, measures for which were embodied in Nolan Patent Office Bill H. R. 11,984.

The next event in these activities of your Committee, following its report of March 22, 1920, the bill having passed the House of Representatives in satisfactory form, was an extended hearing, beginning on April 8, 1920, before the Senate Committee on Patents, on the salaries, force, and damages features of the bill. The personnel of your Committee and of the Society took an active part in this hearing. The chairman of your committee on Patents and Related Legislation made an address before the Senate Patent Committee and introduced a resolution of the Society in favor of the Patent Office bill. The Secretary of the Society, Dr. Charles L. Parsons, appeared at the hearing to represent the Society and seven members of the Society were also present. A stenographic report of the hearings is attached hereto. Although there was a very large delegation present and the Senate Committee seemed to be convinced of the need of passing the bill, substantially as it had come from the House of Representatives, except for some amendments to the provision for fixing damages for infringement, your Committee was greatly surprised and disappointed to find that the Senate Committee reported the bill with what is known as the Federal Trade Commission section attached thereto. This section was intended to give the Federal Trade Commission power to receive and administer inventions and patents of Government employees. It had not been considered at the hearing, and the only justification for attaching it to the Nolan Bill was that it had once passed the Senate and that it would enable the House of Representatives to consider such section with the patent office relief and damages section in a single bill.

It was also necessary in the Senate to have unanimous consent in order that the bill might be brought up before the adjournment of the session. The Chairman of the Appropriations Committee so vigorously opposed the bill that in order to remove his objection to unanimous consent, the Chairman of the Patents Committee of the Senate consented to amendments to the numbers and salaries of the examiners, which emasculated the bill and made it in some respects worse than the present law.

The bill was sent to a Conference Committee, comprising members of both the Senate and House.

The Federal Trade Commission Section had had hearings before the two Patent Committees of Congress, but only those in favor of the bill appeared at the hearings. When the said section was attached to the Nolan Patent Office Bill, it received the attention of many who had not seriously considered it before, and many very strenuous opponents to the section appeared. In view of this, the Conference Committee, contrary to the usual custom, held a hearing on the Federal Trade Commission section for two days in January, 1921. Your Committee presented a resolution of the American Chemical Society urging the Conference Committee to eliminate the Federal Trade Commission section from the bill, in order that the Patent Office relief might not be delayed or prevented from becoming a law by the presence of the said section. Your Committee also took the opportunity to vigorously urge the need of immediate relief for the Patent Office, although the Conference Committee did not invite dis-

cussion of that subject. The Conference Committee reported the bill with the Federal Trade Commission section modified but retained therein, restored the figures for the salaries and numbers of examiners to the condition in which they passed the House of Representatives, and made amendments to the damages section, so that it avoided all the objections raised against it, except that it was a mere codification of the law embodied in the decisions of the courts, which objection is not founded on fact.

The Chairman of your Committee, with representatives of other organizations, went to the Chairman of the Committee on Rules of the House of Representatives and secured the promise of a rule giving the Conference report almost immediate right of way in the House of Representatives. The House promptly voted to approve the Conference report, although, because of objection to the Federal Trade Commission section the majority vote was not large, as it had been when the bill first passed the House without that section.

Because of opposition to the Federal Trade Commission section and the threat that the bill would be talked to death in the Senate on account of the said section, if brought to a vote, the Chairman of the Patent Committee of the Senate did not bring the bill to a vote, and it died with the expiration of the 66th Congress, March 4, 1921.

The Chairman of your Committee spent the last two days of Congress in Washington, seeking to reconcile the opponents of the bill, so that the Patent Office might get its relief, but without success.

A draft of a proposed report, dated March 11, 1921, of your Committee, urging that the Society should oppose the enactment of the Federal Trade Commission section, either as a part of the Patent Office Bill or as a separate bill, and recommending that the Committee on National Policy request each member of the American Chemical Society to write the Committeemen and Members of Congress, urging them to secure the elimination of the Federal Trade Commission section from the bill and the immediate introduction and passage of the bill, and also to prevent the Federal Trade Commission section from becoming a law, even as a separate bill, was sent to the members of the Patent and Related Legislation Committee for vote. As three of the Committee approved of the three recommendations in the report: First, removal of the Federal Trade Commission section from the bill; Second, the immediate introduction and passage of the bill; and Third, that the Federal Trade Commission section should be opposed upon its merits and prevented from becoming a law, and only one member opposing the third recommendation, the remaining member not voting on said third recommendation, the said report was forwarded to the Secretary of the Society, with the request that he bring the report to the attention of the Committee on National Policy and of the Council of the Society for action thereon.

The new Chairman of the Patent Committee of the House of Representatives has re-introduced the Nolan Bill, which was Nolan Patent Office Bill, H. R. 11,984, omitting the Federal Trade Commission section, and the new bill will be known as Lampert Patent Office Bill, H. R. 210. Your Committee is already at work endeavoring to secure the passage of this bill.

Another patent bill has also had the attention of your Committee during the last few weeks of the 66th Congress, namely, Nolan Treaty Patent Bill, H. R. 15,662, which extended the time for filing and prosecuting applications for patents in the United States Patent Office. The reason for this bill was the following:

The International Convention of Paris, of March 20, 1883, to which the United States is a party, provides that if an inventor shall file his applications for patents in any of the Treaty Countries foreign to him within one year after his application has been filed in his own country, then the said foreign applications shall be given the same effect in contest with other inventors and in overcoming alleged prior public uses as if the said foreign applications had been filed simultaneously with the one in his own country; and as the war has prevented many inventors from filing applications in countries foreign to their own within the said one year after their domestic applications, the Peace Treaty and the Berne Convention of June 30, 1920, have extended the time within which to file such applications and to pay fees and take other steps in the prosecution of such applications which were filed or would have been filed during the war without loss of rights; and as many hundreds of applications have been filed and belated fees paid by American citizens in European countries which are parties to said latter Convention and have been accepted by those countries on the supposition that the United States would pass reciprocal legislation; and as the failure to pass such legislation would result in the invalidation of all such applications and payments of fees, Nolan Bill, H. R. 15,662 was introduced for this purpose. This bill protects American citizens from undue effect of filing of applications for patent here by foreign inventors, by reserving a license under any patent granted or validated by reason of the said act to an American citizen, who, before the passage of the act, was *bona fide* in possession of any rights in patents or applications for patents which conflict with any of said patents, and also by preserving to any citizen of the United States, his agent or successors in business, the right to continue any manufacture, use of sale commenced before the passage of such act by such citizen, even though such manufacture, use or sale might infringe a patent granted or validated by reason of the act.

Your Committee was compelled, during the closing days of the Session of Congress, to aid in the passage of this bill, and prepared a resolution in favor of the bill, which was approved by a majority of

the members of your Committee (all who voted), and was forwarded to the Secretary for action by the Public Relations Committee. Before such action could be obtained, the bill was passed both by the Senate and House and became a law.

Respectfully submitted,

EDWIN J. PRINDLE, *Chairman*, Patent and Related Legislation Committee,  
American Chemical Society.

When this report was presented by the Secretary, it was voted that the Society reaffirms its position as to the Nolan Bill and the removal of the Federal Trade Commission "rider" therefrom. Later in these proceedings will be found a second vote placing the Society on record as opposed to the so-called Federal Trade Commission "rider" either as a rider or as a separate bill.

*The Committee on Platinum Theft Control* reported a careful consideration of possible means to decrease the thefts of platinum; that they had done everything they could to make public all data regarding such thefts and had taken up with members of Congress the question of presenting a bill to Congress covering a scheme for licensing platinum refiners, so that all refining would have to be done by firms properly licensed by the United States government, and that this would be given further consideration.

*The Priestley Memorial Committee* reported that the sum of Two Thousand Dollars had been collected and placed on interest; that the Committee had authorized the Chairman to select an artist to copy the Stuart portrait of Priestley, which is now at Northumberland, Pa., and that immediate steps would be taken to obtain a die for the Priestley medal.

*The Committee on the Revision of Methods of Coal Sampling and Analysis (Joint with the Society for Testing Materials)* asked to be continued another year as further tests of an alternate method have not been completed and the tentative method will probably be continued for another year.

*The Committee on Supervision of Chemical Engineering Catalog* reported and the report will be found printed in the May issue of the *Journal of Industrial Engineering and Chemistry*.

*The Supervisory Committee on Standard Methods of Analysis* reported as follows:

The only report acted upon by the Supervisory Committee is that from the Committee on Cottonseed Products, of the Division of Industrial and Engineering Chemists, which was published in the *Journal of Industrial and Engineering Chemistry*, 12, 707, 1920.

A report of the Fusibility of Coal Ash from the Committee on Coal Sampling and Analysis, a joint committee with one from the American Society for Testing Materials, was approved subject to final action by the American Society for Testing Materials, which has published it as tentative. If modified in any way, the report will be again submitted to the Supervisory Committee.

Respectfully submitted,

W. F. HILLEBRAND, *Chairman*, Committee on Standard Methods of Chemical Analysis.

*The World Metric Standardization Committee* reported that the Committee had been active during the year in endeavoring to secure legislation for the introduction of the Metric System in America.

*The Committee on Standard Methods for the Examination of Water and Sewage to Coöperate with the Committee of the American Public Health Association* reported as follows:

The committee met at the call of Mr. W. F. Monfort, chairman of the American Public Health Association committee, at the University of Chicago, December 28-29, at which time the questions with regard to standard methods were discussed in general, and in accordance with the policy of the American Public Health Association, questions were referred to referees as follows:

E. M. CHAMOT, chlorine; nitrates.

W. D. COLLINS, mineral analysis; standard specifications for Nessler tubes; turbidity.

R. E. GREENFIELD, dissolved gases and total hardness.

- H. B. HOMMON, sewage testing methods.  
 H. E. JORDAN, analysis of chemicals used in water treatment.  
 F. W. MOHLMAN, methods for testing sewage.  
 E. B. PHELPS, ammonia in water and sewage.  
 A. M. BUSWELL, definition of alkalinity and temporary hardness.

Respectfully submitted,

A. M. BUSWELL, *Chairman*, American Chemical Society Coöperative Committee.

The Committees appointed by President Smith for the ensuing year will be found on the third page of Proceedings, this issue.

Following the Committee Reports the report of the Patent and Related Legislation Committee was again taken up and after extended discussion the following motion was passed by a vote of 59 in favor, 24 opposed, and 12 not voting:

Moved that the Council of the American Chemical Society go on record as opposed to the substance of Section 9 of the Nolan Bill, H. R. 11984 of the 66th Congress, 3rd Session.

Dr. Charles Baskerville as representative of the Society to the meeting of the American Mining Congress in the Old Colony Club, Biltmore Hotel, March 10, 1921, reported that he was present and took part in the proceedings, and that the Congress had important plans in view for gathering together of data and formulating a plan to assist the Secretary of Commerce.

Dr. Charles Baskerville, the Society's representative in the Holmes Memorial Safety Association, reported that the Association was functioning actively; that the Society had been represented at meetings of the Association, at which local chapters of the Holmes Safety Association were authorized throughout the United States to aid and promote among mine workers and companies a movement for first aid, safety and sanitation.

CHARLES L. PARSONS, *Secretary*.

## MEETINGS OF SECTIONS.

(Full accounts of all meetings should be sent to Secretary Charles L. Parsons, 1709 G St., N. W., Washington, D. C.)

### CALIFORNIA SECTION.

The 123rd regular meeting of the Section was held on April 15, when Arthur Lachman addressed the members on "Molecular Rearrangements in Nitrogen Compounds."

The 124th regular meeting occurred on May 7, the evening being devoted to a program arranged by the women chemists of the Section. The following program was rendered: "Introductory Remarks," by Agnes Fay Morgan, of the University of California; "Blood Regeneration as Influenced by Dietary Factors," by Freda S. Robbins, of the Hooper Foundation for Medical Research; and "By-Products of Research in Organic Chemistry," by Hester E. H. Branch, Graduate Student, Department of Chemistry, University of California.

LLOYD W. CHAPMAN, *Secretary*.

### CHICAGO SECTION.

At the regular meeting of the Section, held on April 22, J. H. Mathews, of the University of Wisconsin, spoke on the subject of "Photochemistry."

S. I. REDMAN, *Secretary*.

### CONNECTICUT VALLEY SECTION.

The last meeting of the season was held at Westfield, Mass., on May 21. George C. Whipple, of the Harvard Engineering School, Cambridge, Mass., spoke on "Water Purification."

HARRY WESSELS, *Secretary*.

### DETROIT SECTION.

The 125th meeting of the Section occurred on May 18 when H. M. Pier, of the Research Corporation, New York City, gave a lecture on the Cottrell Precipitation Process.

WM. B. TEMPLETON, *Secretary*.

### INDIANA SECTION.

The Section held its regular monthly meeting on May 14, at Lafayette, Ind. William Hoskins, of Chicago, spoke on the subject, "The Genesis of an Industry."

EDGAR B. CARTER, *Secretary*.

### IOWA SECTION.

A joint meeting of the Ames and Iowa Sections was held on April 29 and 30, at Indianola, Ia., in connection with the meeting of the Iowa Academy of Science. The following program was given: "Further Work in the Study of Free Energy of Aqueous Solutions," by J. N. Pearce and H. B. Hart, of the State University of Iowa; "The Effect of Relative Positions of the Hydroxide and Amino Radicals in the Migration of Acyl from Nitrogen to Oxygen," by L. Charles Raiford and H. A. Iddles, State University of Iowa; and "A Chemical Study of Dolomites," by Nicholas Knight, Cornell College.

L. CHARLES RAIFORD, *Secretary*.

## KANSAS CITY SECTION.

On April 20, the Kansas City Section joined the Engineering School at Lawrence, Kansas, in celebrating the 30th anniversary of the founding of the school as a separate branch.

LEE E. CLARKE, *Secretary*.

## LEHIGH VALLEY SECTION.

On May 5, the Lehigh Valley Section met at Easton, Pa., when C. O. Brown, of the Semet-Solvay Co., Syracuse, N. Y., gave an address on the "Application of Research to the Coal and Coke Industry."

J. G. SMULL, *Secretary*.

## LEXINGTON SECTION.

The 70th meeting of the Section was held on April 20. A paper, by Edwin J. Gott and John B. Nelson, on the subject, "The Work and Purpose of the Bacteriological Division of the Department of Public Service Laboratories," was read.

S. D. AVERITT, *Secretary*.

## LOUISVILLE SECTION.

At the regular monthly meeting of the Section, on April 15, Otto Eisenschimal, of Chicago, gave a talk on "The Chemist as a Business Man."

C. E. GEIGER, JR., *Secretary*.

## MAINE SECTION.

On April 14, E. H. Winslow, of Portland, Me., addressed the members of the Section on "The Manufacture and Uses of Acid Resisting Clay Products."

L. J. WALDBAUER, *Secretary*.

## MARYLAND SECTION.

The 50th meeting of the Section was held on April 22. J. C. W. Frazer, of the Johns Hopkins University, spoke on "The Catalytic Oxidation of Carbon Monoxide," and Niel E. Gordon, of the University of Maryland, gave an address on the subject, "The Hydrogen Electrode and Its Application." Attendance, 30%.

On Sunday, April 24, a meeting was held in memory of the late Prof. H. N. Morse, of Johns Hopkins University, when prominent scientists paid high tribute to the memory of Professor Morse.

C. C. HOWES, *Secretary*.

## MICHIGAN AGRICULTURAL COLLEGE SECTION.

On March 15, R. L. Kahn, of the Michigan Department of Health, spoke before the Section on the subject, "Some Recent Immunological Studies."

At a meeting, held on April 12, H. C. Young, of the Michigan Agricultural College, addressed the members of the Section on "Vitamines in Relation to Plant Life."

W. G. Smeaton, of the University of Michigan, spoke to the members on May 6, taking as his subject, "Chemical Revolution Effected by Lavoisier and the Early Development of Modern Chemistry."

On May 10, Frank Schaffer, of the Laboratory Apparatus Company, Ann Arbor, Mich., gave a demonstration in glass blowing before the Section.

C. S. ROBINSON, *Secretary*.

## MIDLAND SECTION.

At the regular meeting of the Section, held on April 25, N. W. Haynes spoke on "The Tariff Situation."

C. C. KENNEDY, *Secretary*.

## MILWAUKEE SECTION.

Glen Pickard, of the Pickard Research Laboratories, Chicago, Ill., addressed the Section on April 15 taking as his subject, "The Manufacture of Vegetable Oils."

The section held a joint meeting with the American Society of Steel Treaters on May 9. H. F. Moore, of the University of Illinois, spoke on the "Fatigue of Metals."

O. A. CHERRY, *Secretary*.

#### MINNESOTA SECTION.

R. A. Gortner addressed the March meeting of the Section, speaking on the subject "Colloid Problems in Baking."

L. M. HENDERSON, *Secretary*.

#### NASHVILLE SECTION.

The 73rd meeting of the Section occurred on May 6. The following papers were read: "New Developments in the Tennessee Dairy Industry," by Lucius P. Brown; "Sanitary Principles in Milk Production," by Kary C. Davis; "Possibilities of Sweet Potato Syrup Manufacture in Tennessee," by R. E. Kremers; and "Report from the Rochester Meeting," by George L. Clark. In addition to the above program, a reel of motion pictures on "Condensed Milk" was run.

The following officers have been elected for the coming year: J. M. Breckenridge, *Chairman*; J. W. Sample, *Vice-Chairman*; H. A. Webb, *Secretary-Treasurer*, and Lucius P. Brown, *Councilor*.

H. A. WEBB, *Secretary*.

#### NEBRASKA SECTION.

On March 24, H. C. Russell, of the University of Nebraska, addressed the members of the Local Section on "The Acidity of Different Soils."

At the regular meeting of the Section, held on April 11, E. C. Franklin, of Leland Stanford Jr. University, spoke on "Liquid Ammonia and the Ammonia System of Acids, Bases and Salts." Attendance, 50%.

S. B. ARNSEN, *Secretary*.

#### NEW HAVEN SECTION.

The last spring meeting of the Section occurred on May 24, at New Haven, Conn., when Roger Brunel, of Bryn Mawr, lectured on "The Bearing of Recent Theories of Atomic Structure on Organic Chemical Reactions."

BLAIR SAXTON, *Secretary*.

#### NEW YORK SECTION.

A joint meeting of the Local Section, the American Electrochemical Society and Societe de Chimie Industrielle, was held on April 22, at the Chemists' Club. The program was as follows: "Hoist Machinery in Chemical Industry," by E. W. Taylor; "Industrial Trucks and Tractors," by W. P. Kennedy; "Economics in Handling Liquid Coal Tar Products," by S. P. Miller; and "Mechanical Handling of Materials in Large Scale Chemical Operations," by A. E. Marshall.

The annual meeting of the American Section of the Societe de Chimie Industrielle, in joint session with the American Chemical Society, the American Electrochemical Society, and the American Section of the Society of Chemical Industry, was held on May 13, at the Chemists' Club. The following addresses were given: Presiding Officer's address by Marston T. Bogert; "The Industrial Reconstruction in France," by Marcel Knecht, and "The Diamond and Its Industrial Uses," by George F. Kunz.

H. G. SIDEBOTTOM, *Secretary*.

#### NORTH CAROLINA SECTION.

At the Spring Meeting of the Section, held on April 30, at Wake Forest, N. C., the following program was rendered: "*p*-Cymene Studies. II. The Bromination of 2-Amino-*p*-cymene," by Alvin S. Wheeler and Ira W. Smith; "Chlorination with the Silent Electrical Discharge," by Paul Gross; "New Derivatives of 2, 3, 8-Tribromo-5-hydroxy-1, 4-naphthoquinone," by Alvin S. Wheeler and T. M. Andrews; "A Simple

Density Vapor Apparatus," by Paul Gross; "Analysis and Properties of Some Interesting Combustible Compounds," by O. J. Thies, and "A Note on the Minor Test for Dextrose and Tartrates," by G. H. Satterfield.

L. B. RHODES, *Secretary*.

#### NORTHEASTERN SECTION.

The 167th regular meeting of the Section was held on May 20, when the following addresses were given: "Chemistry in a Clothing Store," by Earl B. Millard; "Recent Researches on Coffee, Dehydrated Foods, and Fish." Two reels of moving pictures were exhibited on "Sidelights of the Mammoth Amoskeag Plant," and "Cotton Manufacturing."

L. F. HAMILTON, *Secretary*.

#### PITTSBURGH SECTION.

The 172nd meeting of the Section, held on May 19, was addressed by Dr. Edgar F. Smith, President of the American Chemical Society, on the subject, "A Glance at the Early Inorganic Chemistry of America."

GEBHARD STEGEMAN, *Secretary*.

#### PUGET SOUND SECTION.

On April 27, E. Z. Lynn, of the University of Washington, spoke before the members of the Section on "Some Reactions of Nitroso Compounds."

R. W. ELLISON, *Secretary*.

#### ROCHESTER SECTION.

At the regular meeting of the Section, held on April 18, the following officers were elected: H. T. Clark, *Chairman*; O. I. Chorman, *Vice-Chairman*; E. M. Billings, *Secretary-Treasurer*; J. Ernest Woodland, Ivar N. Hultman and Harry A. Carpenter, *Executive Committee*.

ERLE M. BILLINGS, *Secretary*.

#### SAINT LOUIS SECTION.

A paper entitled, "A New Isomer of Phenolphthalein and Its Properties," was given before the Section on May 2, by L. McMaster and George D. Graves, of Washington University.

H. A. CARLTON, *Secretary*.

#### SOUTHEAST TEXAS SECTION.

At the regular meeting of the Section, on May 12, J. R. Neller, of the Texas Company, spoke on "A Survey of Chemical Research in Agriculture."

P. S. TILSON, *Secretary*.

#### SOUTHERN CALIFORNIA SECTION.

On April 28, J. W. Turrentine, of the United States Department of Agriculture, Bureau of Soils, spoke to the members on the subject, "Chemicals from Kelp."

H. L. PAYNE, *Secretary*.

#### DECEASED.

Briggs, T. Lynton, 188 Central, Flushing, N. Y. Died April 2, 1921.

Pond, G. G., State College, Pa. Died May, 1920.

Sillman, Joseph, 1685 Jos. Campan St., Detroit, Mich. Died February, 1921.

Wette, Francis A., 204 N. Monroe St., Baltimore, Md. Died, 1920.

Willis, A. R., 1471 Irving St., Washington, D. C. Died April 25, 1921.

# Proceedings.

## COUNCIL.

President Smith has appointed Prof. B. B. Boltwood the Society's representative at the inauguration of Dr. James Rowland Angell as president of Yale University on Wednesday, June 22nd.

### MEMBERS ELECTED BETWEEN MAY 15 AND JUNE 15, 1921.

- Ackerman, D. E., 39 Penn Ave., Mansfield, Ohio.  
Adams, W. C., 727 Union Ave., St. Louis, Mo.  
Anderson, Thomas Colby, 412 Camden Court, Ann Arbor, Mich.  
Battermann, A. E., 6619 Wade Park Ave., Cleveland, Ohio.  
Blusievicz, Michael, 1041 Bloomfield St., Hoboken, N. J.  
Brailley, Allen Gilbert, R. F. D. No. 2, Box 57, South Royalton, Vt.  
Brown, Ellis, St. Elmo Hall, University, Va.  
Campbell, Dugald N., Kempthornes Chemical Works, Westfield near Okahuhu, Auckland, New Zealand.  
Cardinaux, Paul, Laval University, Quebec, Canada.  
Chivers, J. H., Electric Alloy Steel Co., Charleroi, Pa.  
Cowgill, George R., 2 Hillhouse Ave., New Haven, Conn.  
Cutter, Harold B., 3 Linncean St., Cambridge 38, Mass.  
Damon, Edmund Ives, 24 Main St., W., Waterloo, N. Y.  
Damon, Sherman, 295 Kent St., Brookline, Mass.  
Davis, Russell H., 9603 Quebec Ave., Cleveland, Ohio  
Denison, George A., Box 268, Faculty Exchange, College Station, Tex.  
Domovs, Sidney, 2848 W. 22nd St., Brooklyn, N. Y.  
Donald, Robert M., 225 W. 18th St., care of N. K. Fairbank Co., Chicago, Ill.  
Duane, Arthur R., 9 Massachusetts Ave., Boston, Mass.  
Duerr, Winslow A., Cornwall-on-Hudson, N. Y.  
Dougall, Stafford R., 156 Nutts Ave., Phoenixville, Pa.  
Elder, Lucius W., Jr., 115 N. Wayne Ave., Wayne, Pa.  
Friedman, William E., 308 Tompkins Ave., Brooklyn, N. Y.  
Gartmann, Peter, Box 67A, R. F. D. No. 1, Orange, Cal.  
Gerard, Harry F., Scripps Biological Institute, La Jolla, Cal.  
Gordon, David, 131 Wildey St., Tarrytown, N. Y.  
Gridley, Stanley T., 1276 Melbourne Road, East Cleveland, Ohio.  
Griffith, Palmer W., Danby, Vt.  
Guerrero, Alberto Lobo, Box 137, Mass. Inst. of Tech., Cambridge 39, Mass.  
Haggenmacher, H. E., 121 W. 74th St., New York City.  
Hall, Wm. McLaurine, Jr., 240 East Broad St., Bethlehem, Pa.  
Hammond, J. M., 828 Lindsey Building, Dayton, Ohio.  
Hance, Francis E., Morse Hall, Ithaca, N. Y.  
Hartsfield, J. D., 533 Main St., Waurika, Okla.  
Hemmi, Fumiwo, P. O. Box 565, Station A, Champaign, Ill.  
Heurich, Vincent Christian, 403 S. 12th St., Lebanon, Pa.  
Hilman, Victor E., Crompton & Knowles Loom Works, Worcester, Mass.  
Hitchcock, Thomas J., Glebe Sugar Refining Co., Ltd., Greenock, Scotland.  
Holland, C. V., Eastville, Va.  
Jewell, Charles Henry, Y. M. C. A. Building, Woonsocket, R. I.  
Jolliffe, Ernest H., 124 Lyndhurst Ave., Toronto, Ont., Canada.  
Just, Julius F., 616½ So. Galena Ave., Freeport, Ill.  
Kampert, George J., 234 N. 16th St., Kansas City, Kans.  
Kennedy, Eugene H., Newark, Del.  
Kenyon, Wm. Houston, Jr., 61 Broadway, New York City.  
Klein, Charles, 87-20 Boulevard, Rockaway Beach, N. Y.  
Koenig, F. Otto, Jr., 1 West 89th St., New York City.  
Krone, Otto August, 4614 S. Grand Ave., St. Louis, Mo.  
Lachman, John H., 73 Oakland St., Red Bank, N. J.  
Lambright, John., 2211 Grandview, Cleveland, Ohio.  
Leonard, C. E., care of C. B. Smith, 36 N. Gift St., Columbus, Ohio.

- Lutz, Robert F., 91 Park St., Newton, Mass.  
 Macormac, Alfred R., 86 Elliott Ave., Tottenville, N. Y.  
 Marks, Frank H., 1002 Fairmont St., Washington, D. C.  
 Marples, Major M. E., 5 Robinson Road, Shanghai, China.  
 McLachlan, John Arthur, 66 8th Ave., Bezendehart Valley, Johannesburg, South Africa.  
 Mudd, Stuart, 4 Winthrop Hall, Cambridge, Mass.  
 Panganiban, Elias H., College of Agriculture, University of the Philippines, Los Banos, P. I.  
 Patrick, Joseph C., Frigorifico Armour de La Plata, Calle Reconquista 314, Buenos Aires, Argentina, S. America.  
 Pendergast, Edward Hatton, 48 Bicknell St., Dorchester, Mass.  
 Postma, S., 53 Deventerweg, Zutphen, Holland.  
 Pritchard, Walter S., 1222 Rozelle Ave., Cleveland, Ohio.  
 Reese, J. Donald, 233 N. Pearl St., Crestline, Ohio.  
 Richardson, H. E., Mechanicsville, N. Y.  
 Robinson, Jesse, 7 Wave St., Cambridge, Mass.  
 Rosenfield, Harry, 132 Ziegler St., Roxbury, Mass.  
 Rumley, G. G., Roxana Petroleum Corp., Wood River, Ill.  
 Rutember, Charles B., 339 Seminary Ave., Carlinville, Ill.  
 Saenger, George W., Maize Products Pty., Ltd., Melbourne, Australia.  
 Schlundt, H. F., Chuquicamata, Chile, Chile Exploration Co., via Autopagasta, S. America.  
 Silverman, Louis, 1118 N. Euclid Ave., Pittsburgh, Pa.  
 Small, Lyndon F., 208 Warren St., Needham, Mass.  
 Spencer, Ernest F., Russia Cement Co., Gloucester, Mass.  
 Stevenson, Henry Arthur, Demerara Bauxite Co., Ltd., Akyma, British Guiana.  
 Stewart, Gertrude M., 2720 Salena St., St. Louis, Mo.  
 Stock, H. J., 12 Springhurst Ave., Toronto, Canada.  
 Sullivan, Willard Edmond, Lux Ave. & Pine Terrace, South San Francisco, Cal.  
 Suttle, Henry M., Viroqua, Wis.  
 Taylor, F. N. 1024 Ramona St., Corona, Cal.  
 Tooby, John J., 1000 Charles River Road, Cambridge 38, Mass.  
 Ulick, Joseph Carlyle, 4934 N. 9th St., Logan, Philadelphia, Pa.  
 Valin, Aime, 2 Place Youville, Montreal, Canada.

 Westinghouse Lamp Company, Bloomfield, N. J.

## MEETINGS OF SECTIONS.

(Full accounts of all meetings should be sent to Secretary Charles L. Parsons, 1709 G St., N. W., Washington, D. C.)

### CHICAGO SECTION.

On May 20, at the regular monthly meeting of the Section, Julius Stieglitz, of the Department of Chemistry, the University of Chicago, and Ex-President of the

American Chemical Society, gave a lecture on "The Electrical Theory of Oxidation." Attendance 34%.

The Annual Willard Gibbs Dinner and Award of Medal for 1921 to Mme. Marie Sklodowska Curie of the Curie Institute, College de France, occurred on June 14. The presentation address was by Julius Stieglitz, of the University of Chicago, and a review of Mme. Curie's work was made by H. N. McCoy.

S. I. REDMAN, *Secretary*.

#### CINCINNATI SECTION.

The 243rd regular meeting of the Section was held on May 18, when H. S. Fry spoke on "Electronic Tautomerism of Benzene Derivatives."

C. H. LUND, *Secretary*.

#### COLORADO SECTION.

The following officers for the Colorado Section have been elected: John B. Ekeley, chairman; R. S. Hiltner, vice chairman; C. W. Botkin, treasurer; Ruth B. Vertrees, secretary; W. D. Engle and S. J. Osborn, councilors.

RUTH B. VERTREES, *Secretary*.

#### DELAWARE SECTION.

At the regular meeting of the Section, held on May 2, Raymond F. Bacon, Director of the Mellon Institute, Pittsburgh, Pa., spoke on "The Technology of the American Sulfur Industry." After the lecture two moving pictures of "The Story of Sulfur" were shown.

On May 25, Edgar F. Smith, President of the American Chemical Society, addressed the members of the Section on "A Glance at the Early Organic Chemistry in the United States."

E. C. LATHROP, *Secretary*.

#### INDIANA SECTION.

The annual banquet of the Section was held on June 17, followed by a program for the entertainment of the members and guests.

EDGAR B. CARTER, *Secretary*.

#### IOWA SECTION.

On May 6, E. C. Franklin, Professor of Organic Chemistry in Leland Stanford Jr. University, addressed the Section on "Ammonium Compounds." The lecture was accompanied by actual demonstration work.

LEE E. CLARE, *Secretary*.

#### LEXINGTON SECTION.

The 71st meeting of the Section was held on May 26. The members made a visit to the plants of the Kentucky Steel Products Company and the Great Southern Refinery Company.

S. D. AVERITT, *Secretary*.

#### LOUISIANA SECTION.

On Friday, May 20, Carl F. Speh addressed the Section on "The Naval Stores Industry: Its Products and Their Industrial Importance."

H. R. STEVENS, *Secretary*.

#### MARYLAND SECTION.

The 51st meeting of the Section was held on May 27, when Ira B. Remsen addressed the members on "Personal Reminiscences of Sir William Ramsay." John W. Harrington, of the American Chemical Society News Service, spoke on the publicity work of the Society.

C. CLIFTON HOWES, *Secretary*.

## MINNESOTA SECTION.

L. S. Palmer, of the Department of Agricultural Biochemistry, University of Minnesota, addressed the Section on June 2, his subject being "Some Problems in Dairy Chemistry."

L. M. HENDERSON, *Secretary*.

## NEW YORK SECTION.

At the regular monthly meeting of the Section, held on June 10, the following program was given: "Committee on Industrial Alcohol of the American Chemical Society," by Martin H. Ittner; "Industrial Alcohol and Its Relation to Prohibition Enforcement from the Manufacturers' Standpoint," by M. C. Whitaker; "Industrial Alcohol and Its Relation to the Pharmaceutical and Perfumery Industries," by W. L. Crounse; "Industrial Alcohol and Its Relation to the Flavoring Extract and Food Industries," by F. M. Boyles; "Legal Status of Industrial Alcohol and Its Relation to Prohibition Enforcement," by Alfred D. Van Buren. Attendance, 23%.

H. G. SIDEBOTTOM, *Secretary*.

## NORTHEASTERN SECTION.

The regular monthly meeting of the Section occurred on June 10, at the Engineers Club in Boston, when the following program was rendered: "The Microstructure of Wood," by Allen Abram; "The Automotive Fuel Problem," by D. P. Barnard; "The Decolorization of Mineral Oils," by Leon W. Parsons; and "The Role of Compounding Ingredients in Rubber," by C. S. Venable.

L. F. HAMILTON, *Secretary*.

## PHILADELPHIA SECTION.

On May 19, the Section had as its speaker Treat B. Johnson, of Yale University, who took as his subject, "The Study of Organic Reactions Occurring in Living Matter." The after-dinner address was by George K. Helbert on "Concerning Patents."

J. HOWARD GRAHAM, *Secretary*.

## PUGET SOUND SECTION.

A joint meeting between the Local Section of the American Chemical Society and the Students' Section of the University of Washington was held on May 25. Oliver C. Ralston, of the U. S. Bureau of Mines, Seattle Experiment Station, spoke on "The Chemical Phases of the Hydrometallurgy of Zinc," and M. J. Falkenburg, of Seattle, made a report on the general meeting of the Society at Rochester.

R. W. ELLISON, *Secretary*.

## RHODE ISLAND SECTION.

On May 27, W. M. Saunders gave an illustrated talk on the "Lake Superior Iron District."

HERBERT F. DAVISON, *Secretary*.

## ROCHESTER SECTION.

The last meeting of the year, held on May 16, was addressed by the following: John Hudgings, of the Taylor Instrument Company, on "Chemical Thermometers," and R. F. Anderson, of the New York State Agricultural Experiment Station, on "Organic Phosphorus Compounds of Plants."

ERLE M. BILLINGS, *Secretary*.

## SAINT LOUIS SECTION.

On June 6, the following program was rendered before the Section: "Notes on Topping Petroleum," by F. W. L. Tydeman, of the Roxana Petroleum Corporation; and "Corrosion Prevention when Topping Petroleum," by R. R. Matthews, of the Roxana Petroleum Corporation.

H. A. CARLTON, *Secretary*.

## SAVANNAH SECTION.

The seventh regular meeting of the Section was held on May 26. The program consisted of a talk on "Scallops" by J. O. Clarke, and an address on "Some Phases of the Crude Drug Trade," by John J. McManus. Attendance, 50%.

HERBERT P. STRACK, *Secretary*.

## SOUTH JERSEY SECTION.

The eighth regular meeting of the Section was held on April 22. W. Lee Lewis, of Northwestern University, spoke on "Some Aspects of the Chemistry of Bacteria."

C. E. BURKE, *Secretary*.

## SOUTHERN CALIFORNIA SECTION.

At the regular monthly meeting of the Section, on May 26, a paper, entitled "The Lewis-Langmuir Hypothesis of Atomic Structure," by Howard J. Lucas, of the California Institute of Technology, was given.

H. I. PAYNE, *Secretary*.

## TOLEDO SECTION.

On May 13, Harry N. Holmes, Professor of Chemistry at Oberlin College, addressed the Section on the subject, "Emulsions."

The 37th regular meeting of the Section was held on June 3, when A. L. Grainger spoke on "Modern Pottery."

T. E. MOORE, *Secretary*.

## UNIVERSITY OF ILLINOIS SECTION.

The 115th regular meeting of the Section was held on April 20. R. E. Rindfusz, of the American Writing Paper Co., spoke on "The Manufacture of Paper."

S. A. BRALEY, *Secretary*.

## UNIVERSITY OF MICHIGAN SECTION.

On May 3, W. L. Badger addressed the Local Section on the subject of "The Boiling Points of Salt Solutions. Theoretical and Practical Considerations."

On June 7, F. W. Sullivan, Jr., addressed the Section, taking as his subject, "Diphenyl-beta-naphthyl-methyl."

C. C. MELOCHE, *Secretary*.

## UNIVERSITY OF MISSOURI.

The 100th meeting of the Section was held on May 12. A. G. Hogan read a paper on "The Influence of the Plane of Nutrition on the Maintenance Requirement of Cattle." Attendance, 69%.

H. D. HOOKER, Jr., *Secretary*.

## VIRGINIA SECTION.

The 43rd meeting of the Section was held on May 20. B. K. Steadman read a paper on "The Art of Paper Making."

At the last meeting of the Section the following officers for the year were elected: W. C. Jones, chairman; Graham Edgar, vice-chairman; Robert F. McCrackan, secretary-treasurer; W. F. Rudd and Garnet Ryland, councilors.

Robert F. McCRACKAN, *Secretary*.

## WASHINGTON, D. C. SECTION.

The 319th meeting of the Section occurred on May 12. The following program was given: "Quantitative Spectrum Analysis" (Illustrated), by W. F. Meggers, of the Bureau of Standards; "Estimation of Colorless Substances by Spectro-Photometric Methods," by W. E. Mathewson, Bureau of Chemistry; "A Direct Reading Spectro-

## WASHINGTON, D. C. SECTION.

Photometer for Measuring the Transmissivity of Liquids," by I. G. Priest, Bureau of Standards; "Polarimetry," by Frederick J. Bates, Bureau of Standards, and "Crystal Optics in Chemistry" (Illustrated), by F. E. Wright, Geophysical Laboratory.

The 320th meeting of the Section was held on May 25. Moving picture reels on the following subjects were shown: "The Story of Oil," "The Story of Armco Ingot Iron," and "The Story of Sulfur."

J. B. REED, *Secretary*.

## WESTERN NEW YORK SECTION.

At the annual meeting of the Section, held on May 10, the following officers were elected: R. C. Snowdon, Chairman; E. K. Strachan and H. N. Gilbert, Vice-Chairman; W. J. Marsh, Secretary; R. A. Nelson, Treasurer; D. H. Childs, R. H. Power and A. Schwarzman, Executive Committee; Walter Wallace, W. H. Watkins, C. G. Derick and A. M. Williamson, Councilors.

W. J. MARSH, *Secretary*.

## WISCONSIN SECTION.

The April meeting of the Section was held on April 20. Edward Kremers addressed the members on the subject, "Twenty-five Years of Chemical Research on a Typically American Genus of Plants."

At the regular monthly meeting of the Section, held on May 18, C. F. Burgess spoke on "The Chemist and the Business Man."

V. L. BOHNSON, *Secretary*.

## DECEASED.

Cohen, Mortimer J., 132 W. 113th St., New York City. Died April 2, 1920.

Gallup, F. L., Chemical Dept., E. I. du Pont de Nemours & Co., Wilmington, Del., Died in year 1920.

Hanley, Marguerite J., 118 W. 14th St., Minneapolis, Minn. Died April 30, 1921.

Lipstate, W. A., Box No. 600, Hastings-on-Hudson, N. Y. Died May 20, 1921.

# Proceedings.

## COUNCIL.

MEMBERS ELECTED BETWEEN JUNE 15 AND JULY 15, 1921.

Alexander, George Lehner, 306 Jackson St., Atchison, Kans.  
Allen, Woodward, 89 State St., Room 72, Boston, Mass.  
Brown, A. B. 211 Frick Building, Pittsburgh, Pa.  
Cooper, Philip, Amite, La.  
Csouka, F. A., 519 N. Highland Ave., Pittsburgh, Pa.  
Daley, Edward S., 5035 Fulton St., Chicago, Ill.  
Decotils, Horace, 116 Beacon Ave., Jersey City, N. J.  
Docter, Myron G., 680 Farwell Ave., Milwaukee, Wis.  
Gaylord, H. M., 25 Broadway, New York City.  
Grant, Albert Weston, Jr., Minnesota By-Product Coke Co., St. Paul, Minn.  
Hansen, Bjarne, Notodden Salpeterfabriken, Notodden, Norway.  
Heon, A. A., 923 Central Ave., Milwaukee, Wis.  
Herried, Myron T., 425 W. Dayton St., Madison, Wis.  
Hill, Albert, 3716 Revere Ct., Cleveland, Ohio.  
Hovland, Clifton R., Zumbrota, Minn.  
Kagesa, Setsuro, Students' Dormitory, Kyoto Imperial University, Kyoto, Japan.  
Klitsche, Charles H., American Blue Print Paper Co., 445 Plymouth Court, Chicago, Ill.  
Lieber, Alexander Dawson, 1117 N. Dearborn St., Chicago, Ill.  
Lewis, Bernard, 26 Lorne St., Dorchester, Mass.  
Lord, Erskine D., 3 Ivy St., Boston, Mass.  
McBurney, John D., 831 Gomer Ave., Cambridge, Ohio.  
Meredith, Henry, 106 Dumaresq St., Hamilton, N. S. W., Australia.  
Meyers, Harry M., 134 Fuller St., Brookline, Mass.  
Neef, Albert, Brusselsdestraat 87a, Maasricht, Netherlands.  
Payne, V. F., Palmer College, Albany, Mo.  
Phillips, E. Malcolm, 37 Hart St., Providence, R. I.  
Pitts, P. R., Acme Evans Co., Indianapolis, Ind.  
Redding, George K., 90 North St., North Weymouth, Mass.  
Rhodes, Irving C., 814 South Hope St., Los Angeles, Cal.  
Shidei, Jitaro, Chemical Institute, College of Science, Imperial University, Kyoto, Japan.  
Sirisook, S., 40 St. Stephen St., Boston, Mass.  
Skinner, Dwight S., 1229 Downing St., Denver, Col.  
Sulzner, C. F., Hotel Willard, 76th & West End Ave., New York City.  
Vogel, Frederick W., 1237 Narragansett Blvd., Providence, R. I.  
Young, A. A., 719 Pine St., Marquette, Mich.

## MEETINGS OF THE SECTIONS.

(Full accounts of all meetings should be sent to Secretary Charles F. Parsons, 1709 G St., N. W., Washington, D. C.)

### ARKANSAS SECTION.

The Arkansas Section of the American Chemical Society was organized on June 13, at the University of Arkansas, Fayetteville, Arkansas, the headquarters of the Section. The welcome address was given by Dean W. N. Gladson, Vice-President of the University. The Fayetteville Chamber of Commerce entertained with a complimentary dinner at the Hotel Washington. The following officers were elected: Charles F. Robinson, president; J. W. Johnson, vice-president; G. W. Roark, treasurer; J. W. Read, secretary; and Harrison Hale, counselor.

J. W. READ, *Secretary*.

### COLORADO SECTION.

At the regular monthly meeting of the Section, held on June 27, M. F. Coolbaugh spoke on "Some Anode and Cathode Reactions."

RUTH B. VETTERSS, *Secretary*.

## MIDLAND SECTION.

On June 1, J. A. Gann addressed the members of the Section, his subject being "Magnesium Piston Alloys." The new officers of the Section are: E. O. Barstow, chairman; M. E. Putnam, vice-chairman; J. A. Gann, secretary-treasurer; W. J. Hale, councilor; Thomas Griswold, Jr., I. A. Harlow, and C. W. Blenkhorn, executive committee.

J. A. GANN, *Secretary*.

## PHILADELPHIA SECTION.

A special meeting was held at the City Club on June 16, the topic for discussion being "Industrial Alcohol and Prohibition Enforcement." The following members of the American Chemical Society addressed the meeting; Martin H. Ittner, E. C. Lathrop, Chas. H. LaWall, A. A. Holmes, W. L. Crounse, George D. Rosengarten, Henry P. Busch.

J. HOWARD GRAHAM, *Secretary*.

## PITTSBURGH SECTION.

The annual outing of the Section was held on June 25. An elaborate program was carried out for the entertainment of the members and guests at "The Pines," near Pittsburgh.

G. STEGEMAN, *Secretary*.

## RHODE ISLAND SECTION.

The annual outing of the Section was held at the Rhode Island State College, Kingston, R. I. B. L. Hartwell, of the Rhode Island Experiment Station, gave a talk on "The Chemistry of Crop Experiments."

HERBERT F. DAVISON, *Secretary*.

## SYRACUSE SECTION.

The 150th regular meeting of the Section was held on May 27. L. E. Wise, of the New York State College of Forestry, spoke on "The Chemical Utilization of Wood."

K. B. NORTON, *Secretary*.

## TOLEDO SECTION.

At the June Meeting of the Section, the following officers were elected for the ensuing year: E. Schragenheim, chairman; Isadore L. Klein, vice-chairman; T. E. Moore, secretary-treasurer; W. B. Holmes, councilor.

T. E. MOORE, *Secretary*.

## DECEASED.

Ducas, B. P., 11 William St., New York City, died June 24, 1921.

Henderson, Ernest G., The Canadian Salt Co., Ltd., Windsor, Ont., Canada, died October, 1920.

Humbert, Ernest, Gresles, Seine Voise, France, died August, 1920.

Jackson, Kendrick C., 1751 Woodland Ave., N., Birmingham, Ala., died May 2, 1921.

Rose, L. H., Colonial Hotel, Chicago, Ill., died May, 1921.

# Proceedings.

## COUNCIL.

MEMBERS ELECTED BETWEEN JULY 15, AND AUGUST 15, 1921.

Abrams, J. H., 1519 N. Franklin St., Philadelphia, Pa.  
Asayeda, Nobutaro Onoda Cement Co., Shokou near Heijo, Korea, Japan.  
Baker, E. Meade, 206 Jackson St., Grove City, Pa.  
Barnes, Kenneth Boyd, 504 North First St., Rockford, Ill.  
Brown, Charles, 664 Walker Ave., Woodhaven, N. Y.  
Carleton, Phillips A., P. O. Box 13, New Westminster B. C. Canada.  
Cordero, Miguel, la Guerrero M. C. Hda de Su. Pedro, Coyoacan, Mexico.  
Cox, Irwin W., 1420 N. Ohio St., Lawrence, Kans.  
Daffin, John Baker, Arkansas College, Batesville, Ark.  
Deegan, Charles J., 217 W. Huron St., Chicago, Ill.  
Dougherty, D. J., 7701 Goodman Ave., Cleveland, Ohio.  
Farren, John W., P. O. Box 64, Grove City, Pa.  
Finn, George E., 10210 Kinsman Road, Cleveland, Ohio.  
Finney, Robert Spencer, 142 West 80th St., New York City.  
Hamby, T. P., Box 32, Athens, Tenn.  
Humphrey, Elizabeth, Montgomery, W. Va.  
Joss, Ernest J., Haskell, Okla.  
Kroh, James H., 1129 Lowry St., Duquesne, Pa.  
Kutscher, Charles F., P. O. Box 25, Grove City, Pa.

### CORPORATE MEMBERS.

Tinctura Laboratories, Inc., 85 Fort Greene Place, Brooklyn, N. Y.

## MEETINGS OF SECTIONS.

(Full accounts of all meetings should be sent to Secretary Charles L. Parsons,  
1709 G St., N. W., Washington, D. C.)

### CALIFORNIA SECTION.

The 24th Special Meeting of the California Section was in conjunction with the annual meeting of the Pacific Division of the American Association for the Advancement of Science, University of California, Berkeley, Cal., on August 5, 1921. The following program was given:

"Crystal Cleavage in Relation to Crystal Structure," by Dr. Arthur A. Noyes, California Institute of Technology.

"The Crum-Brown Substitution Rule and the Structure of Benzene," by Dr. Julius Stieglitz, University of Chicago, Acting Professor of Chemistry, Stanford University.

"Elementary Electrode Potentials," by Dr. Gilbert N. Lewis, University of California.

"Falsification in Early Chemical History," by Dr. J. M. Stillman, Stanford University.

"Ammono and Mixed Aqua Ammono Carbonic Acid," by Dr. E. C. Franklin, Stanford University.

"Studies in Protein Chemistry," by Dr. Carl Alsberg, Stanford University.

"The Crystal Structure of Potassium Cyanide," by Mr. Milton Bozarth, California Institute of Technology.

"Crystallographic Evidence in Regard to the Structure of Benzene," by Maurice L. Huggins, University of California.

LLOYD W. CHAPMAN, *Secretary-Treasurer*.

#### DECEASED.

Earnest J. Lederle, 453 Green Ave., Brooklyn, N. Y. Died July 21, 1921.

### NOTICE TO CANDIDATES INTENDING TO APPLY FOR A GRANT FROM THE "VAN'T HOFF FUND" FOR THE AID OF INVESTIGATORS IN THE FIELD OF PURE AND APPLIED CHEMISTRY.

According to the regulations of the "Van't Hoff-fund" founded June 28th, 1913, persons interested are notified that the foundation located in Amsterdam under the supervision of the Royal Academy of Sciences appropriates, from the income of the fund, annually, before March 1st, allotments to investigators in the field of pure and applied chemistry, who shall have applied for such a grant to the Committee charged with considering the applications and awarding the funds allotted.

At present this Committee is constituted as follows: A. F. Holleman, President; S. Hoogewerff, A. Smits, J. P. Wibaut, Secretary. If desirable the Committee may appoint still other members for one year only, to coöperate in judging the applications.

The names of persons to whom a grant is allowed, will be published. The grantees are requested to send to the Committee copies of papers giving the results of their work; but otherwise they are at liberty to choose the manner of publication, as well as the journal, in which to publish their results, only mentioning the fact, that the research was made with an appropriation from the "Van't Hoff-fund."

The amount available for 1922 is about fifteen hundred Dutch florins. Applications should be mailed registered to: Het bestuur der Koninklyke Akademie van Wetenschappen; bestemd voor de Commissie van het "Van't Hoff-fonds," Trippenhuys, Kloveniersburgwal, te Amsterdam, with a detailed account of the proposed use of the grant, the amount required, and the reasons upon which the candidates ground their claim. They must be received before November 1st, 1921.

In the name of the Committee of the "Van't Hoff-fund,"

A. F. HOLLEMAN, *President*,  
J. P. WIBAUT, *Secretary*.

Amsterdam, the month of July, 1921.

# Proceedings.

## GENERAL MEETING MINUTES.

The 62nd General Meeting of the American Chemical Society was called to order at Columbia University, New York City on Wednesday morning, September 7, 1921, with President Edgar F. Smith presiding. The welcoming address was delivered by Dr. John E. Teeple, Chairman of the New York Section, to which Dr. Smith responded in behalf of the Society.

The address of Hon. Francis P. Garvan on "Chemistry and the State" roused the audience to a high pitch of feeling regarding the present critical situation which chemistry in America is facing. The address of Sir William J. Pope on "Chemical Warfare" and of Professor R. F. Ruttan on "Organization of Industrial Research in Canada" were also received with enthusiasm. The addresses in full will appear in the October issue of the JOURNAL OF INDUSTRIAL AND ENGINEERING CHEMISTRY.

Dr. Smith read the following telegram of greeting from President Harding, which had been originally received as the visiting guests crossed the border into the United States at Niagara Falls on Monday, September 5, 1921:

President Edgar F. Smith,  
American Chemical Society.

It is a pleasure to extend greetings to the gathering of American, Canadian and British Societies representing the chemical sciences and industries meeting on American soil. Probably none of the materialistic sciences holds promise of so great contributions to human welfare in the coming generations as that which your organization represents. The developments of applied chemistry involve both a possibility of vastly increased horrors in human conflict and alternately inestimable benefits to a peaceful civilization. Let us hope that a science so fraught with either good or vicious possibilities may be turned, through the wisdom of the nations, to the benefit and advancement of mankind.

WARREN G. HARDING.

The telegram was received with enthusiasm and the Society requested President Smith to express its appreciation in a suitable reply.

In accordance with the nominations of the Council, Sir William Pope and M. Paul Kestner were elected Honorary Members of the Society. Sir William responded in a delightful vein and expressed the extreme regret of M. Kestner at his inability to attend these meetings. Dr. Robert F. Ruttan, president-elect of the Society of Chemical Industry, and Dr. Ernst Cohen of the University of Utrecht were presented to the audience and heartily received.

The Committee appointed by the Council consisting of Messrs. H. T. Clarke, F. R. Eldred; and Chas. H. Herty submitted the following resolution, which was unanimously adopted:

Believing in the incalculable peace-time benefits which accrue from the development of the science of organic chemistry and its application in medicine, agriculture and the industries connected with foods, fuels, textiles and dyes;

Realizing the great rôle that organic chemistry has played in the development of chemical warfare, we call the attention of this nation to the grave crisis which threatens our organic chemical industry.

In spite of the tremendous strides made during the past five years in the United States, this important industry is still centered in Germany. Other nations have already sought to safeguard its future in their countries by appropriate legislation. America stands hesitant. Progress has been checked and indeed the very industry is threatened with destruction. Two agencies will be determinative in averting this disaster, the approaching International Conference on Disarmament and the Congress of the United States.

*Resolved, therefore,*

First, that we urge upon the American delegates to the Disarmament Conference most serious consideration of the broad question of chemical armament as affected by the development and maintenance of the chemical industries in the several nations.

Second, that we urge upon Congress the necessity of including in the permanent tariff bill a selective embargo for a limited period against importation of synthetic organic chemicals, and we express the confident hope that in view of the important bearing of such action on economical development and on national defense, our representatives regardless of political affiliations will support this legislation.

The fiftieth anniversary of Sir James and Lady Dewar's marriage having been recently celebrated, on August 8th, it was moved that a congratulatory message be transmitted from the American Chemical Society.

On Tuesday evening a complimentary smoker, with nearly one thousand members present, was held at the Waldorf-Astoria, and an interesting program consisting of music, vaudeville entertainment, cartoons, etc., was enjoyed by all.

At the International Meeting on Thursday afternoon, after an organ recital by Professor Samuel A. Baldwin in the grand hall of the College of the City of New York, which was greatly enjoyed by all, the following addresses were given:

**CHEMISTRY AND CIVILIZATION.**—Dr. Edgar F. Smith. Provost Emeritus, University of Pennsylvania, in the chair.

*Speakers.*

**SCIENCE AND CIVILIZATION: THE ROLE OF CHEMISTRY.**—Dr. Chas. Baskerville, Director of the Laboratories, College of the City of New York; Chairman, International Committee.

**ENERGY: ITS SOURCES AND FUTURE POSSIBILITIES.**—Dr. Arthur D. Little, Chemical Engineer and Technologist, Boston.

**THE ENGINEER: HUMAN AND SUPERIOR DIRECTION OF POWER.**—Dr. Leo H. Baekeland, Honorary Professor of Chemical Engineering, Columbia University.

**CHEMISTRY AND LIFE.**—Sir William J. Pope, Professor of Chemistry, Cambridge University.

**THEORIES.**—Dr. Willis R. Whitney, Head of Research Department, General Electric Company.

**RESEARCH APPLIED TO THE WORLD'S WORK.**—Dr. C. E. K. Mees, Head of Research Department, Eastman Kodak Company.

**PROBLEM OF DIFFUSION AND ITS BEARING ON CIVILIZATION.**—Professor Ernst Cohen, Professor of Chemistry, University of Utrecht.

**CATALYSIS: THE NEW ECONOMIC FACTOR.**—Prof. Wilder D. Bancroft, Professor of Physical Chemistry, Cornell University.

On Thursday evening the banquet hall at the Waldorf-Astoria was crowded at one of the Society's delightful gatherings, and on Friday night the members listened to the annual presidential address of Edgar F. Smith, entitled "Progress in Chemistry." This address was preceded by the unveiling of the Priestley Portrait, which is to be placed in the National Museum, the unveiling being accompanied by a description of the life and work of Priestley, by Dr. C. A. Browne.

The following Divisions and Sections met: Divisions of Agricultural and Food Chemistry, Biological Chemistry, Chemistry of Medicinal Products, Dye Chemistry, Fertilizer Chemistry, Industrial and Engineering Chemistry, Leather Chemistry, Organic Chemistry, Physical and Inorganic Chemistry, Rubber Chemistry, Sugar Chemistry, Water, Sewage and Sanitation Chemistry, and Sections of Cellulose Chemistry, Chemical Education, and Petroleum Chemistry.

At the meeting of the Division of Biological Chemistry a Committee was appointed, consisting of A. D. Emmett, Chairman, Alfred Hess, E. V. McCollum, L. B. Mendel, and H. C. Herman, to study and make recommendations regarding the standardization of methods for vitamine study.

Full details of the meetings of the Divisions will be found in the October issue of

the JOURNAL OF INDUSTRIAL AND ENGINEERING CHEMISTRY. The Divisions elected officers as follows:

- DIVISION OF AGRICULTURAL & FOOD CHEMISTRY: Chairman, T. J. Bryan; Secretary, C. S. Brinton.
- DIVISION OF BIOLOGICAL CHEMISTRY: Chairman, H. B. Lewis; Secretary, J. S. Hughes; Executive Committee, R. D. Swain, R. A. Dutcher, H. C. Sherman, H. F. Zoller, A. D. Emmett.
- DIVISION OF CHEMISTRY OF MEDICINAL PRODUCTS: Chairman, E. B. Carter, Secretary, E. H. Volwiler; Executive Committee, A. D. Hirschfelder, Charles E. Caspari.
- DIVISION OF DYE CHEMISTRY: Chairman, W. J. Hale; Vice-Chairman, L. A. Olney; Secretary-Treasurer, R. Norris Shreve; Executive Committee, B. A. Ludwig, R. E. Rose.
- DIVISION OF FERTILIZER CHEMISTRY: Chairman, F. B. Carpenter; Secretary, H. C. Moore.
- DIVISION OF INDUSTRIAL & ENGINEERING CHEMISTRY: Chairman, W. K. Lewis; Vice-Chairman, D. R. Sperry; Secretary, H. E. Howe; Asst. Secretary, E. M. Billings; Executive Committee, W. F. Hillebrand, Edward Mallinckrodt, Jr., F. M. DeBeers, Alexander Silverman, H. R. Moody, C. E. Coates.
- DIVISION OF LEATHER CHEMISTRY: Chairman, J. A. Wilson; Vice-Chairman, J. S. Rogers; Secretary, A. W. Thomas; Executive Committee, Frank L. Seymour-Jones, R. H. McKee.
- DIVISION OF ORGANIC CHEMISTRY: Chairman, H. T. Clarke; Vice-Chairman and Secretary, F. C. Whitmore.
- DIVISION OF PHYSICAL & INORGANIC CHEMISTRY: Chairman, S. E. Sheppard; Secretary, R. E. Wilson; Executive Committee, Wm. Blum, Joel Hillebrand, J. H. Mathews, L. C. Newell, H. B. Weiser, E. C. Bingham, G. S. Forbes.
- DIVISION OF RUBBER CHEMISTRY: Chairman, C. W. Bedford; Vice-Chairman, H. E. Simmons; Secretary, A. H. Smith; Executive Committee: W. B. Wiegand, W. W. Evans, J. B. Tuttle, D. F. Cranor, F. G. Breyer.
- DIVISION OF SUGAR CHEMISTRY: Chairman, S. J. Osborn; Vice-Chairman, F. W. Zerban; Secretary-Treasurer, F. J. Bates; Executive Committee: C. A. Browne, C. E. Coates, W. D. Horne, W. B. Newkirk, H. S. Paine, H. E. Zitkowski.
- DIVISION OF WATER, SEWAGE & SANITATION; Chairman, A. M. Buswell, Vice-Chairman, F. R. Georgia; Secretary-Treasurer, W. W. Skinner; Executive Committee, W. R. Copeland, W. D. Collins.

CHARLES L. PARSONS, *Secretary*.

## DIRECTORS' MINUTES.

The Directors met at the Chemists' Club, New York City, at 8 P.M., September 6th, with President Smith in the Chair, and Messrs. Bancroft, Bigelow, Little, Talbot, Teeple and Parsons present.

It was voted that the Treasurer be authorized to pay the unusual bills of the JOURNAL OF INDUSTRIAL AND ENGINEERING CHEMISTRY due to the strike.

The Treasurer reported the following transactions in the funds of the Society, which were duly approved by the Directors:

The Treasurer will report the following transactions:

Bought

May 20	Columbus County, N. C.	\$10,066.44	Due 9/1	Temporary
May 27	City of Bristol	19,741.67	Due 7/20 and 9/15	Temporary

July 13	First 4 $\frac{1}{4}$ Liberty Bonds \$5,500 par value, reinvesting funds from Bonds which matured July 1	4,823.73		Morris Loeb
Aug. 22	City of Knoxville	19,870.00	Due 9/30	Temporary
Maturities				
May 10	Pan American Trading	\$7,500.00		Temporary
May 10	Birdsong Bros.	6,680.06		Temporary
July 1	5 Northern Pacific CB&Q	5,000.00		Morris Loeb
July 1	1 Northern Pacific CB&Q	1,000.00		General Inv.
July 20	City of Bristol	10,000.00		Temporary
Aug. 19	City of Spartanburg	10,300.00		Temporary
Sept. 1	City of Memphis	10,300.00		Temporary

It was voted to authorize the Treasurer to make loans and pledge the collateral of the Society therefor to an amount not to exceed \$40,000 when in his judgment it is necessary to do so to meet any excess of expenditures over receipts on 1921 account.

An appropriation of \$250.00 to Chemical Abstracts was made for the fitting up of an additional room.

It was voted that the Eschenbach Printing Company be given notice by the 1st of October, as required by the contract, that new bids on printing will be requested.

It was voted that the Secretary be authorized to sign a lease for the rooms now occupied by the Secretary's office for October 1921 to October 1922 on the basis of \$180.00 a month.

It was voted that the Editor of the *Journal of Industrial and Engineering Chemistry* be authorized to accept any proper advertisements, irrespective of their country or origin.

The Secretary presented requests from foreign libraries and individuals for complimentary copies of the Society's publications, the requests being necessary in the opinion of those making them on account of the present rate of exchange. It was voted that the Secretary insert an advertisement in the Society's journals bringing to the attention of members the need of the journals by certain universities and scientific laboratories, in order that they might make donations thereto if they see fit. It was the opinion of the Directors, however, that the Society itself, in view of the fact that it is at present facing a deficit, is not in position to make such donations.

The ad interim report of the Finance Committee, which was present, indicated that the actual expenditures for the year 1921 are apt to exceed the receipts by approximately \$10,000.

The meeting then adjourned.

CHARLES L. PARSONS, *Secretary*.

### ADVISORY COMMITTEE MINUTES.

The Advisory Committee met at the Chemists' Club, New York City, on Tuesday, September 6th, at 12 o'clock, with President Smith in the Chair and Messrs. Howe, Nichols, Rosengarten, and Parsons present.

The Secretary was instructed to put no names of companies on the programs of meetings nor to include a paper as coming from any particular laboratory or having other than an individual, or individuals as authors.

An invitation was presented for the American Chemical Society to be represented at the inauguration of John Martin Thomas as President of the Pennsylvania State College, Friday, October 14th. Dr. Edgar F. Smith was designated as the delegate.

The Advisory Committee recommended to the Directors that the Editor of the

Journal of Industrial and Engineering Chemistry be authorized to accept all proper advertisements, irrespective of their country or origin.

The Advisory Committee directed the Secretary to present the names of Wm. M. Burton and Hugh K. Moore to the Secretary of the New York Section of the Society of Chemical Industry as their suggestion of recipients of the Perkin Medal.

CHARLES L. PARSONS, *Secretary*.

## COUNCIL MINUTES.

The Council of the American Chemical Society met in Rumford Hall, Chemists' Club, New York City, at 3 P.M., Tuesday, September 6, 1921, with President Edgar F. Smith in the chair, and the following Councilors present:

*Ex-Officio*.—W. D. Bancroft, W. D. Bigelow, F. B. Carpenter, E. J. Crane, A. B. Davis, A. W. Dox, C. H. Herty, H. N. Holmes, A. D. Little, W. H. Nichols, W. A. Noyes, C. L. Parsons, H. P. Talbot, J. E. Teeple.

*Councilors-at-Large*.—H. E. Howe, L. W. Jones, Wm. McPherson, A. Rogers, G. D. Rosen-garten.

*Local Sections*.—*Arkansas*, Harrison Hale. *California*, R. E. Swain. *Chicago*, T. J. Bryan, W. V. Evans (subs. for A. M. Taylor), D. K. French (subs. for R. J. Quinn), C. H. Jones (subs. for L. M. Tolman), H. N. McCoy, G. A. Menge (subs. for W. R. Smith), L. V. Redman, G. L. Wendt (subs. for C. S. Miner), F. C. Whitmore (subs. for W. D. Richardson). *Cincinnati*, H. M. Campbell (subs. for C. P. Long), M. B. Graff, A. P. Mathews. *Cleveland*, A. W. Smith. *Columbus*, M. Hollingsworth (subs. for W. E. Henderson), A. M. Patterson (subs. for G. O. Higley). *Connecticut Valley*, J. S. Chamberlain, C. R. Hoover. *Delaware*, G. M. Norman, C. L. Reese. *Detroit*, H. T. Graber (subs. for H. C. Hamilton). *Georgia*, C. E. Brett (subs. for T. C. Law). *Indiana*, F. R. Eldred. *Iowa*, Edward Bartow. *Kansas City*, F. B. Dains. *Lehigh Valley*, E. C. Bingham. *Louisiana*, C. E. Coates. *Maryland*, H. R. Gundlach, B. F. Lovelace. *Midland*, Wm. J. Hale. *Milwaukee*, E. J. Kern (subs. for G. N. Prentiss), J. A. Wilson. *Minnesota*, R. A. Gortner (subs. for E. P. Harding), C. A. Mann. *Nebraska*, F. W. Upson. *New Haven*, W. R. Hibbard. *New York*, Chas. Baskerville, C. A. Browne, C. E. Davis, F. E. Dodge, V. C. Edwards, Ellwood Hendrick, M. H. Ittner, D. W. Jayne, James Kendall, A. C. Langmuir, K. G. MacKenzie, L. J. Matos, R. H. McKee, F. J. Metzger, C. F. Roth, H. G. Sidebottom (subs. for David Wesson), G. C. Stone, G. W. Thompson, B. R. Tunison, L. van Doren (subs. for S. A. Tucker), R. G. Wright, J. E. Zanetti (subs. for D. D. Van Slyke). *North Carolina*, A. S. Wheeler. *Northeastern*, G. L. Coyle, W. C. Durfee, G. S. Forbes, W. L. Jennings, J. F. Norris, R. S. Weston, R. E. Wilson (subs. for W. K. Lewis). *Omaha*, Wm. M. Barr. *Philadelphia*, G. E. Barton, E. C. Bertolet, W. C. Carnell, J. S. Goldbaum, J. H. Graham (subs. for A. M. Comey), E. F. Hicks, H. S. Miner, W. T. Taggart. *Pittsburgh*, H. V. Churchill, A. C. Fieldner, Alex. Silverman, H. C. Weber (subs. for J. O. Handy), E. R. Weidlein (subs. for E. W. Tillotson). *Rochester*, H. T. Clarke, H. LeB. Gray. *Savannah*, H. S. Bailey (subs. for F. N. Smalley). *South Dakota*, B. A. Dunbar. *South Jersey*, H. D. Gibbs (subs. for Wm. Kirk). *St. Louis*, E. Mallinckrodt, Jr. *Syracuse*, R. A. Baker (subs. for A. C. Houghton). *Univ. of Illinois*, Roger Adams, *Univ. of Michigan*, A. H. White (subs. for H. H. Willard). *Washington*, Wm. Blum (subs. for F. C. Smithers), W. M. Clark, W. D. Collins, A. Seidell, R. B. Sosman. *Western New York*, C. G. Derick, A. M. Williamson. *Wisconsin*, Victor Lenher.

The following report of the Patent and Related Legislation Committee was pre-sented.

### REPORT

—OF THE—

### PATENT AND RELATED LEGISLATION COMMITTEE

—ON—

### STANLEY PATENT BILL, S. 1838.

A bill has been introduced in the United States Senate, which seeks to amend our patent law in a way that requires the gravest attention from all who are interested in our patent system.

This bill, Stanley Patent Bill, S. 1838, while seemingly harmless on its face, is believed by your Committee on Patent and Related Legislation to be, on the one hand, of little practical value to accomplish the purpose for which it is introduced, and, on the other hand, to involve possibilities of great harm to the patent system as a whole.

The bill was introduced at the request of the Secretary of War because inventions relating to ordnance, which had been made by American engineers and not patented by them, are being patented on applications for patent which have been sold to the Krupps, so that there is apparently danger of our not being able to use in our own defense inventions made by Americans. The Stanley bill seeks to prevent this situation by granting patents to aliens only on condition that the government shall

have the right to grant licenses under the patents, unless they are worked to an adequate extent in this country within two years from their issuance.

Your Committee wishes to state at the outset that the remedy for this situation lies in proving, when suit is brought under such a patent, that the invention was made and publicly used in this country and was not originated by the German patentee. Proof of these facts would result in the patent being held to be invalid. It is not necessary to introduce a compulsory working clause into our patent system as a defense against such a patent.

If the purpose of the law is also to discourage the Germans from taking out patents in the United States, that also would seem to be ineffective. For, if the invention is one of sufficient value, so that Americans would want licenses under the patent, it would be of enough value to make it worth while for the Germans to manufacture in this country to prevent the monopoly being weakened or destroyed by the granting of licenses under the patent. If the invention were of so little importance that it was not worth while for the Germans to work it in this country, then it would probably be of so little value that no one would want a licence under the patent.

If United States patents were only granted to Germans under such onerous terms that they were not worth while taking out, then where the invention were of such a nature that it could be practiced secretly, such as chemical inventions, the Germans would only manufacture in Germany and not patent it anywhere, and thus our public would be deprived of that knowledge of the invention which would be obtained from a patent, and by which they could practice the invention when the patent had expired.

To the extent to which the Bill would compel the Germans to manufacture in this country, it would tend to cause that "peaceful penetration" which was so objectionable before we went into the war and which we took so much trouble to root out during the war.

The infant dye industry in this country is seeking protection from German competition and is now protected by an embargo preventing the importation of German dyes which are adequately manufactured in this country. It is imperative that we have a well-equipped and extensive dye industry in this country. The German dye industry was the root and foundation of Germany's manufacture of explosives, poison gases, and means of protection from poison gases. It was because the chemistry of these munitions of war is intimately related to the chemistry of dyes and because the dye plants were readily converted to war uses that Germany was enabled to produce such enormous quantities of explosives, against which there was no immediate defense. The protection and encouragement of a dye industry and other chemical industries are therefore necessary measures for our defense. It would therefore seem highly unwise to put pressure on the Germans, through our patent laws, to manufacture in this country.

There is some belief among legislators and others that a compulsory working requirement, under penalty of having licenses granted, should be applied to all United States patents, whether granted to domestic or foreign inventors, and if the Stanley bill were enacted making such a requirement as to patents granted to foreign inventors, it would be an entering wedge by which there is danger that such a requirement would be applied to our patents generally. This your Committee believes would be disastrous to our patent system.

The prime object of our patent system was to induce the production of inventions. The reward held out as an inducement to invent was an exclusive monopoly of the invention for seventeen years, during which time the inventor might make money out of the invention if it had merit and he had business ability enough to supply it to the public.

The path of the inventor is already strewn with difficulties and a large proportion of inventors make little or nothing from their inventions, and if those which would otherwise be successful are handicapped much more than they are to-day, your Committee believes that the production of inventions will be greatly decreased.

Our patent system has been of inestimable value to our country and more than any other factor has helped to place our country in the position of the greatest inventive, manufacturing and agricultural country in the world. Therefore, changes in that system should only be made after the most mature consideration and a clear demonstration that those changes will either increase, or at least not impair, the production of inventions.

Among the harmful reactions of a compulsory working requirement are the following:

An invention which is admirable in itself may find no market for many years because the things or conditions with which it has to work have to grow up to the advance made by the invention. In such a case the expense of working the invention—and it would always be considerable—would be entirely lost, and usually the inventor would allow the patent to lapse for failure to work. If, as not infrequently happens, such an invention would find a good market during the later years of its life, which could not have been foreseen when the patent was issued, the patentee and other inventors seeing what he had lost by the compulsory working requirement would be embittered against the patent system and would cease to invent.

Most concerns which buy or manufacture under patents will not have anything to do with them unless they can have a complete monopoly. Where licenses have been granted under a patent for failure to commercially work the invention, the salability of the patent would usually be largely destroyed for this reason.

The making of an invention to-day is not usually the making of a single patent, but is the result of a long development through which a series of patents is taken out, and often auxiliary inventions are patented, such as machines, apparatus or processes for making the desired product. Thus, the inventor or manufacturer would have a group of patents whose dates of issue would be scattered along over a series of years. Although it would not be known until the end of the development had been reached whether the enterprise would ever justify going on the market, each of the series of patents would have to be worked under the Stanley Bill within two years after it was issued under penalty of having a competitor have a license under that patent, although the license might be demanded just for the purpose of making trouble with the enterprise. If this were the situation, even large corporations would often hesitate to face the expense involved in perfecting a patent and would refrain from development, to the loss of the public.

If the law were changed, as proposed in the Stanley Bill, the wealthy man could afford to obtain patents, while the poor man could not. It is one of the proud distinctions of our patent system that its doors are open equally to all men. Many a man in the United States has raised himself from the bench to the ownership of a business by his inventions. There are many businesses to-day which are founded upon the inventions of their principal owners, who made them when they were poor men.

If the compulsory working requirement had benefitted those countries in which it is a feature of their patent laws, there would be more reason for trying it in the United States, but there is no country which at all approaches the number of patents or valuable inventions per capita that are produced in the United States. Even the very small inventions which are brought into being by our patent system are often of great value to the public, although they may be of no value to their inventors, because they lead a development along step-by-step until it reaches a point from which some one sees an opportunity to make a really great advance in the art.

In 1832 the United States enacted a compulsory working clause, but in 1836 it was repealed, and no such clause has ever been re-enacted.

Your Committee believes that, as a practical matter, the Stanley Bill would only accomplish a comparatively small amount of good and on the other hand its possibilities for harm are so great that it would be exceedingly unwise to make it a law, and your Committee therefore respectfully advises that the American Chemical Society exercise its influence to prevent the enactment of the bill.

Respectfully submitted,

EDWIN J. PRINDLE,  
E. A. HILL,  
A. SCHMIDT,  
C. P. TOWNSEND,  
EDMOND O'NEIL.

After extended discussion it was felt that the report as it stood might give a wrong impression of the Society's feelings if presented unchanged to Congress. It was accordingly voted:

"While the Council is disposed to accept the views of its Committee on Patents, nevertheless it is felt that a constructive suggestion should be made by the Committee as to legislation which would prevent the utilization of our patent office by foreigners for the suppression of the development of industries, such as was so clearly apparent in the organic chemical industry upon our entrance into the war in 1917. The Committee is therefore urged to consider this problem immediately and to report to the Committee on National Policy."

The Council voted to form a Division of Sugar Chemistry. The following by-laws presented by the Sugar Section, being found to be in conformity with the constitution and by-laws of the Society, were adopted by the Council.

#### CONSTITUTION OF THE DIVISION OF SUGAR CHEMISTRY AND TECHNOLOGY OF THE AMERICAN CHEMICAL SOCIETY.

##### ARTICLE I.

##### *Name and Object.*

*Sec. 1.* The name of this organization shall be the Division of Sugar Chemistry and Technology of the American Chemical Society.

*Sec. 2.* The object of the Division shall be the stimulation of interest, the encouragement of research and the diffusion of information in all that pertains to the chemistry and technology of sugars.

*Sec. 3.* It is not the purpose of this organization to supplant other local organizations of American sugar chemists or technologists already existing or that may exist, but rather to coöperate with these associations for promoting the objects which they have in common.

## ARTICLE II.

*Membership.*

*Sec. 1.* There shall be two classes of members:—active and associate.

*Sec. 2.* Active membership shall be open only to members of the American Chemical Society. Any such member, who is interested in the object of the Division and who shall apply to the Secretary-Treasurer, can be enrolled as an Active Member.

*Sec. 3.* Any person who is interested in the object of the Division and who is not a member of the American Chemical Society may be enrolled as an Associate Member.

*Sec. 4.* Associate Members shall be entitled to all privileges of the Division, save that of voting for officers and of holding office; provided, that such associate members shall not be entitled to any of the other privileges of the American Chemical Society, and shall pay dues of two dollars (\$2.00) per annum, in addition to such other dues as the Division may require. Associate Members may become Active Members upon joining the American Chemical Society.

## ARTICLE III.

*Officers.*

*Sec. 1.* The officers of the Division shall be a Chairman, a Vice-chairman, a Secretary-Treasurer, and an Executive Committee.

*Sec. 2.* The Executive Committee shall consist of the Chairman, Vice-chairman, Secretary-Treasurer and six other active members of the Division.

*Sec. 3.* At the first session of the Division during the annual meeting of the American Chemical Society and following the report of the Secretary-Treasurer, the Chairman shall appoint from the members present at the meeting, a committee of three to nominate officers for the ensuing year. This committee shall present its list of nominations immediately before the election of officers at the last session of the Division during that annual meeting.

*Sec. 4.* All officers shall be elected by ballot of the Active Members present at the last session of the Division during the annual meeting of the American Chemical Society, and shall take office at the close of the meeting at which they were elected. They shall hold office for one year or until their successors are elected.

*Sec. 5.* Vacancies of office which may occur between meetings shall be filled by the Executive Committee.

*Sec. 6.* It shall be the duty of the Chairman to represent the Division in the Council of the American Chemical Society, to preside at the meetings of the Division and of its Executive Committee, and to execute the decisions and recommendations of this Committee.

*Sec. 7.* In the absence of the Chairman the duties of his office shall be filled by the Vice-Chairman.

*Sec. 8.* It shall be the duty of the Secretary-Treasurer to record and preserve the minutes and proceedings of the Division and of the Executive Committee, to keep a list of the Active and Associate members, to send members such notices as may be required and any available reprints of papers which are read at the meetings, to transmit to the Secretary of the American Chemical Society the names of all officers and committees of the Division within three weeks of their appointment and to notify the Secretary of the American Chemical Society of any changes in officers and committees during the year. The Secretary-Treasurer shall also have charge of the funds of the Division and shall make such disbursements therefrom as may be authorized by the Executive Committee.

*Sec. 9.* The Executive Committee shall manage the affairs of the Division and shall appoint, and direct the work of, the special committees. As early as possible at each general meeting of the Society the Executive Committee shall meet to consider the business of the Division and receive the reports of the special committees. The Executive Committee shall authorize the disbursements of funds to be made by the Secretary-Treasurer.

## ARTICLE IV.

*Sec. 1.* There shall be a meeting of the Division at each general meeting of the American Chemical Society. The order of business shall be as follows:

Reading of Minutes.

Report of Executive Committee.

Report of Secretary.

Appointment of Nominating Committee (first session of annual meeting).

Report of special committees and discussion.

Reading of papers and discussions.

Report of Nominating Committee (last session of annual meeting).

Election of officers (last session of annual meeting).

Miscellaneous business.

*Sec. 2.* Members of the Division who may desire to meet at other times than those of the two general meetings of the American Chemical Society have the privilege of participating in the monthly meetings of any of the local sections of the American Chemical Society.

#### ARTICLE V.

##### *Special Committees.*

*Sec. 1.* The Chairman, with the advice and approval of the Executive Committee, shall appoint such standing committees as may be necessary to consider, transact and report upon, special matters of business.

#### ARTICLE VI.

##### *Publications.*

*Sec. 1.* The official organs of the Division shall be the *Journal of the American Chemical Society* and the *Journal of Industrial and Engineering Chemistry*. Authors who intend to publish the papers which are read before the Division must submit their contributions to the editor of either of these journals before they can be published elsewhere.

*Sec. 2.* If the editors consider a paper too technical, or for any other reason, unsuited for publication in the Society's Journals, the author is then at liberty to publish it in such sugar trade or other periodicals as he may desire, with the statement, however, that the paper was read before the Division at a specified meeting of the American Chemical Society.

*Sec. 3.* Authors, who publish papers that are read before the Division, shall, in all cases, order for the Secretary-Treasurer a sufficient number of reprints, as uniform as possible in 6 inch x 9 inch size, to supply the active and associate members of the Division, any cost for such reprints to be paid by the Secretary-Treasurer from the funds of the Division.

*Sec. 4.* The Executive Committee may at its discretion and with the approval of the Council of the American Chemical Society, provide for the issue of other publications.

#### ARTICLE VII.

##### *Decision of Questions.*

*Sec. 1.* All questions concerned with organization, such as election of officers, rules of procedure, order of business, etc., shall be decided at the meetings of the Division by a vote of the Active Members, then and there present.

*Sec. 2.* All questions not concerned with organization, such as methods of analysis and general matters of policy, shall be decided only by letter ballot of all Active Members of the Division and such decisions to be effective must be approved by the Council of the American Chemical Society.

#### ARTICLE VIII.

##### *Assessments.*

*Sec. 1.* The Executive Committee may at its discretion impose dues not to exceed two dollars (\$2.00) per annum upon the Active and four dollars (\$4.00) per annum upon the Associate Members of the Division, such dues for Associate Members to be in addition to the membership dues required under Article II, Section 4. All dues shall be collected by the Secretary-Treasurer and the disbursements therefrom shall be devoted to the purpose of the Division.

#### ARTICLE IX.

##### *Amendments.*

*Sec. 1.* Amendments to this Constitution shall be made only at the Annual Meeting of the Division by a two-thirds majority of the Active Members present, provided that a two months notice of the proposed amendment with the text of the same has been sent to the Active Members of the Division.

*Sec. 2.* The amendments of the Constitution to be effective must be approved by the Council of the American Chemical Society.

It was voted to form a Division of Leather Chemistry. The following by-laws presented by the Leather Section, being found to be in conformity with the constitution and by-laws of the Society, were adopted by the Council.

#### BY-LAWS OF LEATHER DIVISION OF THE AMERICAN CHEMICAL SOCIETY.

##### ARTICLE 1.—NAME.

This Division shall be known as the LEATHER DIVISION of the American Chemical Society.

##### ARTICLE 2.—MEMBERSHIP.

Any member of the Society may become a member of the Division by filling out, signing, and sending to the Recording Secretary of the Division a form essentially the same as that given below

and shall remain a member so long as he fulfills the obligations imposed by the Division upon its members.

FORM OF APPLICATION FOR MEMBERSHIP: I, (*give name in full*), a member of the American Chemical Society, do hereby request the Recording Secretary of the Leather Division to enter my name as a member of the Division and I agree to observe the rules and by-laws of said Division so long as I remain a member.

#### ARTICLE 3.—OFFICERS AND MANNER OF ELECTION.

1. The officers of the Division shall be a Chairman, a Vice-chairman a Recording Secretary, and an Executive Committee consisting of the Chairman, Vice-chairman, Recording Secretary and two registered members of the Division.

2. The Chairman of the Division shall be Chairman of the Executive Committee.

3. The officers of the Division shall be nominated by a committee, appointed by the Chairman, and shall be elected annually by ballot at the last session of the Division, held during the annual meeting of the Society, and shall take office at the close of the meeting at which they were elected. They shall hold office until their successors are elected.

4. The Executive Committee shall fill any vacancies that may occur through death or resignation among officers of the Division.

#### ARTICLE 4.—DUTIES OF OFFICERS

1. It shall be the duty of the Chairman to represent the Division in the Council of the Society; to preside at meetings of the Executive Committee; to carry into effect the decisions and recommendations of that Committee; to preside at stated meetings of the Division; and to report to the Society at its regular meetings.

2. In the absence of the Chairman, the duties of his office shall devolve upon the Vice-chairman.

3. It shall be the duty of the Recording Secretary to keep a record of the proceedings of the Division and of the Executive Committee; to maintain a list of registered members; to send to registered members such notices as the business of the Division may require; and to transmit to the Secretary of the Society the names of all officers and standing committees of the Division within ten days of their appointment, and, in like manner, to notify the Secretary of the Society of any change of officers or standing committees during the year. The Recording Secretary shall be the custodian of the files of the Division; shall make all disbursements, subject to the authorization of the Executive Committee; and shall report to the Division at its annual meeting.

4. The Executive Committee shall conduct the business of the Division and direct its activities. As early as may be, the Committee shall, at each general meeting, hold a meeting to consider the affairs of the Division and receive reports of its committees. The voting majority of the Executive Committee shall be responsible for all expenditures which it may authorize, except so far as the action of the Council shall have previously provided for such expenditures.

#### ARTICLE 4.—MEETINGS.

1. There shall be a meeting of the Division at each annual meeting of the Society and, unless the Division by a two-thirds vote of the registered members present at the preceding annual meeting shall determine otherwise, also at each general meeting of the Society other than the annual meeting. Business affecting the organization of the Division shall be transacted only at the meeting coincident with the annual meeting of the Society.

2. The order of the business shall be as follows:

- a. Reading of minutes of previous meeting.
- b. Reports of the Chairman and Secretary.
- c. Report of the Executive Committee.
- d. Reports of committees and discussions.
- e. Reading of papers and discussions.
- f. Miscellaneous business.
- g. At the Annual Meeting—Election of Officers.
- h. Unfinished business.

The regular order of the business of the Division may be suspended at any session by the consent of two-thirds of the members of the Division present.

#### ARTICLE 6.—SPECIAL AND STANDING COMMITTEES.

The Chairman shall appoint from time to time committees of the Division to consider, conduct, and report upon special matters as may be delegated to them.

#### ARTICLE 7.—PUBLICATION.

The Executive Committee may, at its discretion, provide for the issue of publications for distribution to registered members of the Division, or for sale. The official organs of the Division are to be the *Journal of the American Chemical Society* and the *Journal of Industrial and Engineering Chemistry*.

No paper presented before the Division shall be published in any journal other than those of the Society, until after prior publication in one of the Society's journals, or until the consent of one of the editors of the Society's journals has been obtained.

#### ARTICLE 8.—ASSESSMENTS.

The Executive Committee may, at its discretion, impose dues not to exceed two dollars per year upon registered members of the Division, said dues to be collected by the Secretary, and the receipts therefrom to be devoted to the purpose of the Division. The Executive Committee may drop from the registered membership in the Division the name of any member who is in arrears for dues for over one year.

#### ARTICLE 9.—AMENDMENTS.

These by-laws may be amended at any annual meeting of the Division by a three-fifths vote of the registered members present, provided two weeks notice of the proposed amendment with text thereof has been sent to the registered members of the Division. The amendment to be effective must be approved by the Council and accepted by that body as not inconsistent with the Constitution and By-laws of the Society.

Ten members of the Society having proposed the names of Sir William J. Pope, K.B.E., F.R.S., and M. Paul Kestner for honorary membership in the American Chemical Society, their names were presented to the Council, and having been endorsed in writing by a majority of the Council, as required by the constitution, the Council instructed the Secretary to present their names to the General Meeting for action, with the recommendation of the Council that they be elected.

It was voted, in view of the fact that the South Carolina Section was apparently in a state of coma, not having held a meeting for several years, and the matter having been taken up with the officers of that Section by the Secretary, that the charter of the South Carolina Section be withdrawn.

It was voted to hold the Annual Meeting in September 1922 in Pittsburgh, Pa. It was voted to leave the date of the Spring Meeting to be held in Birmingham, Ala., to the President and the Secretary with power.

Arthur B. Lamb was reelected Editor of the *Journal of the American Chemical Society*. The term of office of Associate Editors G. P. Baxter and H. W. Wiley having been ended by lot, it was voted that their successors be named by Dr. Lamb, subject to the approval of the President.

Charles H. Herty was reelected Editor of the *Journal of Industrial and Engineering Chemistry*, with the following Advisory Board: H. E. Barnard, Chas. E. Coates, Ralph Gould, Wm. Hoskins, A. D. Little, Geo. D. Rosengarten, T. B. Wagner.

E. J. Crane was reelected Editor of *Chemical Abstracts*.

W. A. Noyes was reelected Editor of Scientific Monographs, with the same board of Associate Editors.

John Johnston was reelected Editor of Technological Monographs, and the selection of successors to the two retiring editors, C. L. Reese and C. P. Townsend, was left to Dr. Johnston and the President with power.

Dr. Smith spoke of the work of the Priestley Memorial Committee and of the Priestley portrait presented preceding President Smith's address on Friday evening, and outlined the plans of the Committee to establish a Priestley Medal fund with the remaining funds. President Smith described the plans for the reestablishment of the Priestley home at Northumberland, Pa., and spoke feelingly of his wish that the Society might be able to celebrate its fiftieth anniversary with a meeting at Northumberland in 1925.

The ad interim report of the Finance Committee sent to the members of the Council was brought before the Council for discussion.

The Committee on a proposed amendment to Article 13 of the constitution reported as follows:

The committee have carefully considered the amendment in question and have

consulted the records with reference to requests made by Sections at the present time, as well as the financial condition of the Society. In view of the present conditions the committee recommend that the amendment be not adopted.

H. LEB. GRAY,  
A. V. H. MORY,  
H. E. HOWE.

It was moved that the whole latter be laid on the table until the Annual Meeting in September 1922.

After an extended discussion, the following resolutions were unanimously passed:

WHEREAS, the American Chemical Society has provided through its News Service ample means for reaching the public promptly and uniformly,

Therefore, be it *resolved*:

That officers of all Divisions and Sections are instructed to file with the Secretary of the Society all matter for which they desire publicity, including abstracts, and that this material be supplied only to the News Service through the General Secretary's office.

Whereupon the Director of the News Service presented a report on the method adopted by the News Service for the New York Meeting for the distribution of abstracts and asked for discussion. It was felt that this method would relieve the individual secretaries of the divisions from a great deal of routine work, at the same time establishing a thoroughly coördinated service.

John E. Teeple, President of the Chemists' Club, presented a suggestion that the Society take over the Bureau of Employment now run by the Chemists' Club in New York City or establish a bureau of its own to replace this organization. It was voted that a committee of three be appointed by the President to consider plans and possibilities and report at the Spring Meeting. The President appointed Wm. McPherson, Chairman, Edward Bartow, and A. C. Fieldner.

The Secretary read a letter from the Committee on Publications outlining the progress made since the strike in the printer's plant on May 1, indicating that publications will be on a normal basis by October 1.

Dr. Smith spoke regarding the present legislative situation with regard to the organic chemical industry, whereupon it was moved that a committee be appointed to draft resolutions urging the passage of a limited embargo on synthetic organic chemicals and present them at the General Meeting of the Society. President Smith appointed H. F. Clarke, Chas. H. Herty, and Frank R. Eldred.

The Council directed the Secretary to express its unanimous and hearty thanks to the New York Section, to the members of the various committees, to Columbia University, to the Chemists' Club, to the College of the City of New York, and to others who had extended hospitality to the Society.

The meeting adjourned at 5.10 P.M. At 6.30 the Councilors met in the dining hall of the Chemists' Club for dinner, as guests of the Local Section.

CHARLES L. PARSONS, *Secretary*.

#### MEMBERS ELECTED BETWEEN AUGUST 15 AND SEPTEMBER 15, 1921.

Baizer, Roland W., 636 East 18th St., Brooklyn, N. Y.  
Baril, Georges, Université de Montreal, 185 rue St. Denis, Montreal, Canada.  
Bartlett, W. J., 1721 Coit Ave., East Cleveland, Ohio.  
Bradshaw, Lawrence, 50 East 41st St., New York City.  
Brau, Bozotech C., Vanity Fair Silk Mills, Reading, Pa.  
Brook, George Bernard, British Aluminium Co., Kenochleven, Argyll, Scotland.  
Brown, William, Eastern Smelting Co., Ltd., Daloh Kramat Road, Penang, S. S. Hongkong, China.  
Burton, Georgia W., Greenville Woman's College, Greenville, S. Car.  
Caius, J. F., St. Joseph's College, Trichinopoly, South India.

Caldwell, Mary L., 620 West 116th St., New York City.  
 Caswell, Anne T., Milwaukee-Downer College, Milwaukee, Wis.  
 Catlett, Geo. F. State Board of Health, Raleigh, N. Car.  
 Chen, Kwan-Shun, 104 Harvard Place, Ithaca, N. Y.  
 Cook, Lawrence H., P. O. Box 883, Stanford University, Cal.  
 Eiseman, B. J., Jr., 614 Ponce de Leon Ave., Atlanta, Ga.  
 Elsoffer, Harvey H., 321 S. Division St., Ann Arbor, Mich.  
 Finch, Geo., P. O. Box 134, Elkhart, Indiana.  
 Fleiss, Alois D., Ayacucho 1846, Buenos Aires, Argentina, S. Amer.  
 Flenner, Albert Lawrence, Chem. Dept., University of Maryland, College Park, Md.  
 Hall, J. H., James Island, near Victoria, B. C., Canada.  
 Henderson, William F., Mellon Institute, Pittsburgh, Pa.  
 Henley, Martin S., 316 W. Washington Ave., Jackson, Mich.  
 Hill, Mark, 1017 Speight Ave., Waco, Texas.  
 Hunter, H. Blound, 1506 Brown Ave., Norfolk, Va.  
 Keller, Harry H., 398 Plymouth Ave., Buffalo, N. Y.  
 Ladd, Culver S., Agricultural College, North Dakota.  
 Laselle, Percy, Box 72, Rickreall, Oregon.  
 Lichtenwalner, D. C., Box 258, Riverdale, Md.  
 Macfarlan, Edward J., 219 Law St., Darlington, S. C.  
 Martling, Francis H., 1053 Armstrong, Kansas City, Kans.  
 McCollum, Ella, Mansfield Depot, Conn.  
 McKinney, David S., 1019½ Hallam St., Pittsburgh, Pa.  
 Morine, L. G., Université de Montreal, 185 rue S. Denis, Montreal, Can.  
 Morse, Jared K., 5800 Blackstone Ave., Chicago, Ill.  
 Normand, Alexander Robert, Wilson College, Bombay, 7, India.  
 Otsubo, Takeo, 1010 Main St., Urbana, Ill.  
 Pedersen, Herman, P. O. Padang, Serai, South Kedah, Malay Peninsula.  
 Pietsch, Paul F., Department of Beverage Inspection, Jefferson City, Mo.  
 Plasencia, Leonel, Amargura 59, Havana, Cuba.  
 Quisumbing, Francisco A., College of Agriculture, University of the Philippines, Los Banos, P. I.  
 Rafferty, James A., 30 E. 42nd St., New York City.  
 Salisbury, Henry M., 85 9th Ave., New York City.  
 Schuh, Arthur, 3529 N. Hoyne Ave., Chicago, Ill.  
 Skinner, Eugene W., Doane College, Crete, Neb.  
 Starkey, E. B., University of Maryland, College Park, Md.  
 Suzuki, Rokuo, Aji-no-moto-kojo, Kawasaki-machi, Kanagawa-ken, Japan.  
 Tuttle, Donald E., 2369 Fairview Ave., Cincinnati, Ohio.  
 Watt, Howard R., 919 W. Main St., Norristown, Pa.  
 Watterson, Paul Eldred, Keeler, Cal.  
 Wickey, S. A., Box 164, Sugar City, Col.  
 Wiley, R. C., College Park, Md.  
 Williamson, Herbert P., 655 Yaddin St., Kingsport, Tenn.  
 Williamson, John F. G., 529 East State St., Trenton, N. J.

#### CORPORATION MEMBERS.

Ajax Rubber Company, Inc., Trenton, N. J.  
 Los Angeles Soap Co., 633 East First St., Los Angeles, Cal.

### MEETINGS OF THE SECTIONS.

[Full accounts of all meetings should be sent to Secretary Charles L. Parsons, 1709 G St., N. W., Washington, D. C.]

#### COLORADO SECTION.

The regular meeting of the Section occurred on September 26. John B. Ekeley, of the University of Colorado, spoke on "The Present Status of the American Dye Industry."

RUTH B. VERTREES, *Secretary*.

#### EASTERN NEW YORK SECTION.

At the meeting held on September 16, J. W. McBain, of Bristol University, England, gave a talk on "The Physical Chemistry of Soap." Following him, L. V. King, of McGill University, Canada, Ernst Cohen, of the University of Utrecht, Holland, and Paul Heyman, of the University of Ghent, Belgium, spoke briefly on educational methods in use in their particular institutions.

MARY R. ANDREWS, *Secretary*.

## INDIANA SECTION.

On September 27, Charles E. Ruby, associate professor of physical chemistry at the Massachusetts Institute of Technology, spoke before the members on "The Research at the Physical Chemistry Laboratory of the Massachusetts Institute of Technology."

GEORGE B. WALDEN, *Secretary*.

## LOUISVILLE SECTION.

The first fall meeting of the Section occurred on September 30, when C. E. Ruby, of the Massachusetts Institute of Technology, spoke on "The Work of a Pure Science Laboratory, and Its Relation and Importance to Industrial Research."

C. E. GEIGER, JR., *Secretary*.

## OMAHA SECTION.

The eighth meeting of the Section was held on April 10, when Arthur E. Hall of the American Smelting and Refining Company, spoke on "Bismuth and Its Recovery from Lead Ores."

On May 10, the ninth meeting was addressed by P. J. Deschavsky who discussed the Rochester Meeting. H. A. Senter performed experiments to illustrate the action of solid carbon dioxide.

E. M. PARTRIDGE, *Secretary*.

## American Field Service Fellowships for French Universities.

The Society for American Field Service Fellowships for French Universities will offer for open competition among graduates of American colleges and other suitably qualified candidates a number of fellowships, not to exceed twenty-five, for the purpose of encouraging advanced study and research in French Universities during 1922-23.

## THE FELLOWSHIPS.

The fellowships, of the annual value of \$200 and 10,000 francs, are granted for one year and are renewable for a second year. They may be awarded in the following fields of study:

Agriculture, Anthropology, Archaeology and History of Art, Architecture, Astronomy, Biology, Botany, Chemistry, Classical Languages and Literature, Criminology, Economics, Education, Engineering, English Language and Literature, Geography, Geology, History, Law, Mathematics, Medicine and Surgery, Oriental Languages and Literature, Philosophy, Physics, Political Science and International Law, Psychology, Religion, Romance Languages and Literature, Semitic Languages and Literature, Slavic Languages and Literature, Sociology, and Zoology.

Fellows will be required to sail to France not later than July 1st of the year in which the award is made, to matriculate in a French University for the following session, and to pursue studies in the field of science designated in their awards. They will be expected to send accounts of their studies together with reports of their progress from their instructors.

## DECEASED.

W. B. Cogswell, Solvay Process Co., Syracuse, N. Y. Died June 7, 1921.

Cyril S. Dawes, Colonial Ammunition Co., Ltd., Gordon St., Footscray, Victoria, Australia. Died March 5, 1921.

Frank N. Smalley, P. O. Box 832, Savannah, Ga. Died, 1921.

F. C. Weld, 263 Fairmount St., Lowell, Mass. Died, 1921.

# Proceedings.

## COUNCIL.

MEMBERS ELECTED BETWEEN SEPTEMBER 15 AND OCTOBER 15, 1921.

Blackburn, Paul V., 1565 Woodward Ave., Lakewood, Ohio.  
Carter, Albert S., Carnegie Institute of Tech., Pittsburgh, Pa.  
Ericksen, Andrew C., 34 Gillette Place, Newark, N. J.  
Fuss, Chester G., 609 South Limestone St., Lexington, Ky.  
Green, Frank W., P. O. Box 208, Little Falls, N. J.  
Hazard, C. H., 7 East 42nd St., New York City.  
Kirschberg, Bradley H., 317 Clinton St., Schenectady, N. Y.  
Lansingh, Van Rensselaer, 56 Pine St., New York City.  
Lavett, Chas. O., 831 Elmwood Ave., Buffalo, N. Y.  
Ledbetter, R. H., P. O. Box 297, Bessemer, Ala.  
McLain, Leigh J., Tecumseh, Michigan.  
Merritt, Matthew M., 76 Lafayette St., Salem, Mass.  
Riddle, Oscar, Carnegie Lab., Cold Spring Harbor, L. I., N. Y.  
Shank, John J., Waynesboro, Pa.  
Stallbaumer, Adrian L., St. Benedict's College, Atchison, Kans.  
Stones, Charles W., 36th Floor, 233 Broadway, New York City.  
Thorne, L. G., Alnarp, Akarp, Sweden.  
Von Hagen, Verda, 126 Husband St., Stillwater, Okla.  
Weber, Ione, 14 Morningside Ave., New York City.  
Widmer, J. Max, 1716 8th Ave., E., Cedar Rapids, Iowa.

### CORPORATION MEMBERS.

Metakloth Co., Inc., Lodi, N. J.  
Young Brothers Company, 6500 Mack Ave., Detroit, Mich.

## MEETINGS OF THE SECTIONS.

(Full accounts of all meetings should be sent to Secretary Charles L. Parsons,  
1709 G. St., N. W., Washington, D. C.)

### AMES SECTION.

The officers of the Ames Section for the ensuing year are as follows: F. E. Brown, chairman; E. I. Fulmer, vice-chairman; H. V. Wright, secretary-treasurer; and W. F. Coover, councilor.

H. V. WRIGHT, *Secretary.*

### ALABAMA SECTION.

The following officers for the Alabama Section have been elected: J. F. Carle, chairman; Theodore Ledbetter, vice-chairman; James T. MacKenzie, secretary-treasurer; B. B. Ross, councilor; and C. N. Wiley, J. J. Phillips, and A. G. Overton, executive committee.

JAMES T. MACKENZIE, *Secretary.*

### CALIFORNIA SECTION.

The 126th meeting of the Section occurred on October 7. The speakers were as follows: C. L. Alsberg, director, Carnegie Food Laboratory, Stanford University, on "Studies in Protein Chemistry;" and A. R. Olson, of the University of California, on "The Effect of X-Rays on Certain Chemical Reactions."

BRYANT S. DRAKE, *Secretary pro tem.*

## CINCINNATI SECTION.

The 244th meeting of the Section was held on October 5, when C. E. Ruby, of the Massachusetts Institute of Technology spoke on "The Work of a Pure Science Laboratory and Its Relation and Importance to Industrial Research."

C. H. LUND, *Secretary*.

## CLEVELAND SECTION.

The Section held its first meeting of the season on October 18 and had as its speaker, L. F. Vogt, of the Standard Chemical Company, who spoke on "Radium and its Production."

H. S. BOOTH, *Secretary*.

## CONNECTICUT VALLEY SECTION.

On October 15, Thomas B. Freas, of Columbia University, addressed the members of the Section on "Laboratory Apparatus and Appliances."

H. WESSELS, *Secretary*.

## DELAWARE SECTION.

A. H. Pfund, of the Johns Hopkins University, spoke before the Section, on October 19, taking as his subject the "Measurement of Color as Applied to Industrial Needs."

E. C. LATHROP, *Secretary*.

## DETROIT SECTION.

The 126th meeting of the Section was held on October 19, when the members were addressed by John A. Gann, of the Dow Chemical Company, his subject being "Dow Metal."

The following officers have been elected for 1921: J. C. Moore, chairman; F. O. Taylor, vice-chairman; William B. Templeton, Secretary; and W. G. Walker, treasurer.

WM. B. TEMPLETON, *Secretary*.

## EASTERN NEW YORK SECTION.

The 102nd meeting of the Section, held on October 14, had as its speaker, Lewis Knudson, of Cornell University, who spoke on "Some Investigations on the Organic Nutrition of Plants."

MARY R. ANDREWS, *Secretary*.

## INDIANA SECTION.

At the meeting of the Section, held on October 14, Gerald L. Wendt, of the University of Chicago, spoke on "New Chemistry for Old Chemists."

GEO. B. WALDEN, *Secretary*.

## LEHIGH VALLEY SECTION.

The Section held a meeting on September 28, devoted to a symposium on Engineering Education.

On October 21, H. W. Jordan, of Syracuse, N. Y., addressed the Section, his subject being "The Laws of Evolution that Control Chemistry and Engineering."

J. G. SMULL, *Secretary*.

## MILWAUKEE SECTION.

The regular meeting of the Section was held on October 7, when John A. Wilson, of Gallun & Sons Company, spoke on "The Histology of Skin and the Chemistry of Leather Manufacture."

O. A. CHERRY, *Secretary*.

## NEBRASKA SECTION.

The 99th meeting of the Section, held on September 28, had as its speaker, H. A. Spoehr, of the Carnegie Institution Laboratory, Carmel, Cal., his subject being "The Cosmical Function of Green Plants." On the following day, Doctor Spoehr spoke on "The Nature of the Photo Synthetic Process."

SAUL B. ARENSON, *Secretary*.

## NEW HAVEN SECTION.

The first fall meeting of the Section was held on October 11, at which time Guy C. Givens, director of the research laboratory of the Celluloid Zapon Company, spoke on "The Manufacture and Use of Lacquers."

BLAIR SAXTON, *Secretary*.

## NEW YORK SECTION.

The New York Section, which met on October 7, had as its speaker, E. M. Chamot of Cornell University, his subject being "The Microscope and How the Chemist can use it."

HERBERT G. SIDEBOTTOM, *Secretary*.

## NORTHEASTERN SECTION.

The regular meeting of the Section, held on October 14, was addressed by the following speakers: C. J. James, of New Hampshire College, "The Rare Earths;" and Grinnell Jones, of Harvard University, "The Pending Tariff Bill." Two reels of moving pictures on the subject of "The Making of Soap," were shown.

L. F. HAMILTON, *Secretary*.

## PHILADELPHIA SECTION.

On October 20, Hugh S. Taylor, of Princeton, spoke to the members of the Section, his subject being "The Absorption of Gases by Solids."

J. HOWARD GRAHAM, *Secretary*.

## PUGET SOUND SECTION.

The first fall meeting of the Section was held on September 29, and had as its speakers, Ray W. Clough and Carl R. Fellers, their subject being "Some Scientific Aspects of the Salmon Industry."

R. W. ELLISON, *Secretary*.

## RHODE ISLAND SECTION.

Charles Baskerville, head of the Department of Chemistry, College of the City of New York, addressed the members of the Section, October 18, on "Science and Civilization; The Role of Chemistry."

NELSON BARLOW, *Secretary*.

## ROCHESTER SECTION.

On October 13, Ellwood Hendrick spoke to the members of the section, his subject being "The Chemical Warfare of America."

ERLE M. BILLINGS, *Secretary*.

## SAINT LOUIS SECTION.

On October 3, R. S. Sherwin, of the Aluminum Ore Company, spoke to the members of the Section, his subject being "Metallurgy of Aluminum."

At a special meeting of the Section, held on October 15, H. M. Whelpley spoke on "The Mounds and Mound Builders."

H. A. CARLETON, *Secretary*.

## TOLEDO SECTION.

The regular monthly meeting of the Section, held on October 14, had as its speaker, James R. Withrow, of the Ohio State University, who spoke on "Modern Developments in Chemical Engineering Materials of Construction."

T. E. MOORE, *Secretary*.

## UNIVERSITY OF MICHIGAN SECTION.

H. H. Bartlett, at the regular meeting of the Section, on October 14, addressed the members on the subject of "Primitive Chemical Technology."

C. C. MELOCHE, *Secretary*.

## UNIVERSITY OF MISSOURI.

On September 16, J. E. Underwood, of Denver, Colo., spoke before the meeting of the Section, his subject being "A New Form of Apparatus for Separating and Purifying Radium Emanation from Radium Salts."

H. D. HOOKER, JR., *Secretary*.

## VIRGINIA SECTION.

The 44th meeting of the Section, was held on October 21. Eugene C. Bingham, of Lafayette College, addressed the Section on "Recent Work on Plasticity."

ROBERT F. McCracken, *Secretary*.

## WASHINGTON, D. C. SECTION.

The 321st meeting of the Section occurred on October 13, at which time Edwin E. Slosson, of the Science Service, addressed the members on "The Constructive Chemist."

J. B. REED, *Secretary*.

## WISCONSIN SECTION.

On October 19, the following speakers addressed the Section: J. E. Day, on "A Study of Some Manganese Compounds;" and C. S. Leonard, on "A Recent Visit to European Chemical Laboratories."

V. L. BOHNSON, *Secretary*.

## DECEASED.

S. C. Linbarger, Carborundum Co., Niagara Falls, N. Y., died September 10, 1921.

Joseph W. Richards, Lehigh University, South Bethlehem, Pa., died October, 1921.

Samuel S. Voorhees, Bureau of Standards, Washington, D. C., died September 23, 1921.

# Proceedings.

## DIRECTORS' MINUTES.

The Directors of the American Chemical Society met by call of President Smith at the Chemists' Club, at 3:30 P.M., on Saturday, November 5, with President Smith and Directors Rosengarten, Teeple, Talbot, and Parsons present.

The meeting was called especially to consider the resignation of Charles H. Herty as Editor of the *Journal of Industrial and Engineering Chemistry* and Director of the American Chemical Society News Service and to consider the election of his successor as immediate action was necessary. The following letter of resignation from Dr. Herty was received and ordered spread on the record:

New York,  
October 31, 1921.

Dr. EDGAR F. SMITH, President,  
American Chemical Society,  
Philadelphia, Pa.

*Dear Dr. Smith:*

It is with many feelings of poignant regret that I hereby tender my resignation of the office of Editor of the *JOURNAL OF INDUSTRIAL AND ENGINEERING CHEMISTRY*. It is my hope that the officers of the Society will accept the same and that my successor will be named just as promptly as possible.

I take this step for the reason that on last Friday evening at the meeting of the manufacturers of synthetic organic chemicals in Washington, D. C., I was unanimously elected President of a new organization there and then organized and named Synthetic Organic Chemical Manufacturers of the United States. When the information of the selection was first brought to me, I stated unequivocally that I could not accept it. Later in the evening I was called upon by a large delegation of manufacturers who urged my acceptance and I repeated my declination and the reasons therefor. However, after a three hours' conference they succeeded in putting the matter to me in such a way that I felt it my duty to accept, convinced that through this new channel I could perform a useful public service and perhaps be of even greater helpfulness to the chemists of the country than I could hope to be through continuation of the office of Editor. I therefore did accept.

I shall of course continue to look after the work of the *JOURNAL* until my successor takes office, though I shall be obliged to divide my time between the two organizations. However, I am convinced of the loyal coöperation of the members of our staff here and that there will be no diminution of the activities of the *JOURNAL*.

In conclusion, may I express to you and each officer and member of the American Chemical Society my heartfelt appreciation of that spirit of coöperation and support which has made my five years' incumbency of the office of Editor a continuous joy.

Sincerely yours,  
CHAS. H. HERTY,  
*Editor.*

The Directors voted to accept the resignation to take effect at the earliest possible moment, the exact date to be fixed by President Smith, and a letter of appreciation be sent Dr. Herty by President Smith for his services to the American Chemical Society. As Dr. Herty pressed for immediate release from his editorial duties in order that he might undertake the very important work of the Synthetic Organic Chemical Manufacturers of the United States and asked, if possible, that his successor should actively undertake the handling of the *Journal* by the first of December, the Directors decided that it was necessary to exercise the authority given them by the By-Laws and to act for the Council in the election of a successor to fill out the unexpired term of Dr. Herty, ending January 1, 1923. After careful consideration of some twenty suggestions, H. E. Howe was unanimously elected Editor of the *Journal of Industrial and Engineering Chemistry* and Director of the American Chemical Society News Service. It was voted that the salary of the new editor remain the same as at present and that, if found necessary, the editorial offices be removed to Washington.

It was voted that the Secretary should increase foreign postage on the Journal of Industrial and Engineering Chemistry and on the Journal of the American Chemical Society from seventy-five cents to \$1.00, the combined postage rate remaining, as at present, at \$2.50.

It was voted to call a meeting of the Directors to consider the annual budget on Saturday, December 10, at 3 p.m., at the Chemists' Club.

It was voted to authorize the Secretary, if found advisable, to arrange for a special train previous to the Birmingham Meeting to visit points of interest en route.

It was voted that, as President Smith has been appointed one of the technical members of the Disarmament Conference, the necessary funds to meet his expenses in Washington be appropriated.

It was voted that, in view of the changing nature of the American Chemical Society membership, it was inadvisable to issue an engraved certificate of membership for framing, as had been requested by a few members.

It was voted that in the opinion of the Directors it was unnecessary to register the title of Journal of Industrial and Engineering Chemistry as a trademark in the United States Patent Office, as suggested by one of our members, it being deemed that the copyright was sufficient.

The meeting then adjourned.

CHARLES L. PARSONS,  
*Secretary.*

## COUNCIL.

The following communication was sent to the Council on November 7th:

### COUNCIL OF THE AMERICAN CHEMICAL SOCIETY

Gentlemen:

November 7, 1921

It is with sincere regret that I have to announce to you the resignation of Chas. H. Herty, under date of October 31, 1921, as Editor of the Journal of Industrial and Engineering Chemistry and Director of the American Chemical Society News Service. As already announced in the public press, he has been elected President of the newly organized Association of Synthetic Organic Chemical Manufacturers. He has asked for immediate release, and his resignation has been accepted.

On account of the urgency and the fact that a letter ballot for nomination and election by the Council would require approximately two months, President Smith instructed me to call a meeting of the Directors to elect his successor, the Directors, under the Constitution, being the only body having the authority to act on all matters for the Council when the Council is not in session. The meeting was held Saturday afternoon, November 5th, at the Chemists' Club, New York City.

After careful consideration of the situation, the Directors unanimously elected H. E. Howe, Editor of the Journal of Industrial and Engineering Chemistry and Director of the American Chemical Society News Service, with the understanding that this election involved the removal of the offices to Washington, if accepted.

Mr. H. E. Howe has tentatively accepted the position, but states that he does not feel that he can permanently enter into the work and complete the unexpired term of Chas. H. Herty, ending December 31, 1922, without the assurance that the Council is in full accord with the Directors' action and that he will have their hearty support.

Will you, accordingly, mail to me at the earliest possible moment your opinion in the enclosed ballot envelope. No name should be attached thereto, as it is desired that every Councilor should feel entirely free to express his approval or disapproval of this action.

Yours very truly,

CHARLES L. PARSONS,  
*Secretary.*

The result of the vote was 152 approvals and 12 disapprovals.

## MEMBERS ELECTED BETWEEN OCTOBER 15 AND NOVEMBER 15, 1921.

Austin, Brother, C. S. C., 1324 N. Pennsylvania St., Indianapolis, Ind.  
 Ayer, Richard B., 49 Randolph Hall, Cambridge, 38, Mass.  
 Bartholomew, Tracy, Mellon Inst., University of Pittsburgh, Pittsburgh, Pa.  
 Biddle, Arthur, 428 Ardmore Ave., Trenton, N. J.  
 Boyden, E. Wynne, c/o A. I. Root Co., Medina, Ohio.  
 Burgess, Louis, 152 Avenue B., Bayonne, N. J.  
 Coyne, Bernard B., Morley Chem. Lab., Adelbert College, Cleveland, O.  
 Davis, Claude F., 219 West St., Stillwater, Okla.  
 Davis, Paul K., 446 Grand Ave., Brooklyn, N. Y.  
 Deller, A. William, R. F. D. No. 2, Allendale, N. J.  
 Dickinson, J. R., c/o Mrs. Saunders, University, Va.  
 Dillingham, Winthrop Bulkley, St. Anthony Hall, Williamstown, Mass.  
 Dodds, Herbert Henry, Box 191, La. State University, Baton Rouge, La.  
 Donald, Maxwell B., 12 Inman St., Cambridge, Mass.  
 Drobka, Frank J., 740 Langdon St., Madison, Wis.  
 Glass, Emanuel, Suffern, N. Y.  
 Gregory, Rev. P., Subiaco College, Subiaco, Ark.  
 Haines, Edward C., 1067 Beacon St., Brookline, Mass.  
 Hamilton, Russell, 343 Main St., Wareham, Mass.  
 Hara, Terutaro, Lab. of Applied Chemistry, Imperial University, Kyoto, Japan.  
 Henke, Clyde O., 430 E. Fourth St., Bloomington, Ind.  
 Jephcott, Harry, Glaxo Res. Lab., 56 Osnaburgh St., London, N. W. 1, Eng.  
 Jones, Chester A., 517 Iowa Ave., Iowa City, Iowa  
 Katz, Alexander, 2229 Creston Ave., New York City.  
 Kemmer, Raymond, 1439 W. Bancroft St., Toledo, Ohio.  
 Laub, Leon C., 124 Sussex Ave., Newark, N. J.  
 Leach, Winthrop W., Magnolia Petroleum Co., Beaumont, Texas.  
 Lum, Joe Woon, 155 Willoughby Ave., Brooklyn, N. Y.  
 Marks, B. R., Calydor, Gravenhurst, Ont., Canada.  
 Nesterowicz, J. J., 849 Fillmore Ave., Buffalo, N. Y.  
 Pierce, Dorothy Gordon, 50 Willard Court, Oberlin, Ohio.  
 Piron, Emil H., 43 Broad St., New York City.  
 Robertson, A. F., 373 Upham St., Melrose, Mass.  
 Rubin, Harold, 22 East 93rd St., New York City.  
 Schultz, Raymond, 660 61st Ave., Milwaukee, Wis.  
 Smith, Harrison P., 615 S. Virgil Ave., Los Angeles, Cal.  
 Smyth, Henry Field, School of Hygiene, University of Pa., Philadelphia, Pa.  
 Spicer, H. N., 101 Park Ave., New York City.  
 Taketa, Kichiro, Laboratory of Applied Chemistry, Kyoto, Japan.  
 Teberne, H. Olga, 2326 Camp St., New Orleans, La.  
 Tyndall, Arthur M., 9 Henleaze Gardens, Bristol, England.  
 Wedderburn, Augustus, 1454 Euclid St., N. W., Washington, D. C.  
 Worstell, Richard A., 353 College Ave., Valparaiso, Indiana.

## MEETINGS OF THE SECTIONS.

(Full accounts of all meetings should be sent to Secretary Charles L. Parsons, 1709 G St., N. W., Washington, D. C.)

## AMES SECTION.

The 29th meeting of the Section, held on October 12, was addressed by W. K. Robbins, of Manchester, N. H., taking for his subject, "Science with Practice."

R. A. Gortner, head of the Agricultural Biochemical Department at the University of Minnesota, spoke before the members at the regular monthly meeting of the Section held on November 22, his subject being "Life Processes from the Colloidal Standpoint."

H. V. WRIGHT, *Secretary*.

## CALIFORNIA SECTION.

The 127th regular meeting of the Section was held on November 4, the following addresses having been made: "Science and Education," by Joel H. Hildebrand, of the University of California; "Felt Base Floor Covering," by W. H. Nutting, of the Paraffine Companies.

BRYANT S. DRAKE, *Secretary, pro tem.*

## CENTRAL TEXAS SECTION.

The following officers have been elected by the Section for 1922: C. C. Hedges, president; J. R. Bailey, vice-president; W. W. Battle, secretary-treasurer; and J. L. Brakefield, councilor.

W. W. BATTLE, *Secretary.*

## CHICAGO SECTION.

At the regular meeting of the Section, held on October 21, Paul E. Klopsteg, of the Leeds & Northrup Company, spoke on "Some Practical Aspects of Electrometric Analysis." Informal group meetings followed the address of the evening.

At the regular meeting of the Section, held on November 18, H. C. Parmelee, editor of Chemical and Metallurgical Engineering, addressed the members on "The Technical Magazine and Its Relation to Industry."

S. L. REDMAN, *Secretary.*

## CINCINNATI SECTION.

The 245th regular meeting of the Section, held on November 9, had as its speaker, R. S. Tour, of the University of Cincinnati, his subject being "Engineering Aspects of the Synthetic Ammonia Process."

C. H. LUND, *Secretary.*

## CLEVELAND SECTION.

"Some Technical and Scientific Applications of the Colloid Chemistry of Soaps and Proteins," was the subject of an address by Martin H. Fischer before the members of the Section on November 14.

H. S. BOOTH, *Secretary.*

## COLORADO SECTION.

At the regular meeting of the Section on November 28, Frank E. E. Germann, of the University of Colorado, spoke on "Thermal Analysis as a Method of Discovering New Compounds."

RUTH B. VERTRIES, *Secretary.*

## COLUMBUS SECTION.

On November 29, C. W. Foulk, of the Ohio State University, spoke to the members on the subject of "My Field of Research and What has been Accomplished in it."

EDWARD MACK, *Secretary.*

## CONNECTICUT VALLEY SECTION.

At the annual meeting of the Section, held on November 19, J. S. Chamberlain and L. B. Allyn addressed the members on "Vitamines." The following officers were elected for 1922: J. S. Chamberlain, chairman; G. Albert Hill, vice chairman; George B. Hogaboom, treasurer; Paul Serex, Jr., secretary; J. C. Andrews, Vernon K. Kriebble and W. H. Wooffindale, executive committee; C. A. Hoover and J. A. Newlands, councilors.

PAUL SEREX, JR., *Secretary.*

## DELAWARE SECTION.

The regular monthly meeting of the Section was held on November 30, when James Kendall, of Columbia University, spoke on "A Modified Ionization Theory."

E. C. LATHROP, *Secretary.*

## EASTERN NEW YORK SECTION.

On November 11; Dr. Edgar F. Smith, president of the American Chemical Society spoke before the members of the Section, taking as his subject "Early Organic Chemistry in America."

MARY R. ANDREWS, *Secretary*.

## GEORGIA SECTION.

The following program was given before the members of the Georgia Section, at the regular meeting held on November 5: "Architecture of the Atom," by J. S. Guy; "Chemical Industry in England," by T. C. Law; and a report on the New York meeting, by C. A. Butt.

J. S. BROGDON, *Secretary*.

## INDIANA SECTION.

Taking as his subject, "Life as a Chemical Profession," Benjamin Turner, of the Indiana Medical School, addressed the members of the local Section at the regular monthly meeting, held on November 11.

GEORGE B. WALDEN, *Secretary*.

## IOWA SECTION.

The first fall meeting of the Section was held on October 22. The principal address was given by Ernst Cohen, who discussed "The Diffusion Problem."

As a result of the recent election held by the Iowa Section, the officers to serve for 1922 are as follows: Edward Bartow, chairman; R. W. Getchell, vice chairman; L. Chas. Raiford, secretary-treasurer; J. N. Pearce, counselor.

L. CHARLES RAIFORD, *Secretary*.

## KANSAS CITY SECTION.

The 151st meeting of the Section was held on October 22, at which time J. E. Earnshaw, food and dairy commissioner of Kansas City, gave an address on "The Kansas City Milk Situation." F. B. Dains, of the University of Kansas, reported on the New York meeting.

The 152nd meeting of the Section, held on November 19 at the University of Kansas, Lawrence, Kansas, had as its speaker, E. C. Kinney, who spoke on "Copper Smelting." Attendance, 23%.

LEE E. CLARK, *Secretary*.

## LEXINGTON SECTION.

The 72nd meeting of the Section, which occurred on October 19, was a "get together" meeting. Several short addresses were made, followed by a round table discussion of subjects of interest to the Section. Attendance, 63%.

The following program was given at the 73rd regular meeting, held on November 9: "The Function of Grit in the Chicken Gizzard," by G. D. Buckner; and "No One Nose," by L. A. Brown and C. G. Fuss. Attendance, 44%.

S. D. AVERITT, *Secretary*.

## LOUISIANA SECTION.

At the first meeting of the season, held on October 21, the following program was rendered: "Conservation in Louisiana," by M. L. Alexander, Louisiana State Commissioner of Conservation; "Some Points in the Oil and Gas Situation," by C. S. Williamson, Jr.; and a brief report on the New York meeting, by C. E. Coates.

H. R. STEVENS, *Secretary*.

## MAINE SECTION.

At the meeting of the Section, held on November 9, M. R. Louria addressed the members, the subject of his paper being "Organic Electrochemistry."

J. N. CROMBIE, *Secretary pro tem*.

## MARYLAND SECTION.

On October 28, Charles L. Reese, of the du Pont Company, and Gen. Amos A. Fries, chief of the Chemical Warfare Service, addressed the members of the Maryland Section.

The following officers have been elected for 1922: F. M. Boyles, chairman; S. T. Powell, vice chairman; J. H. Wolfe, secretary-treasurer; Carl Haner, H. H. Lloyd, J. C. W. Frazer, Charles Neil, A. E. Marshall, and A. W. Warth, executive committee; E. E. Reid, J. H. Shrader, and W. B. D. Penniman, councilors.

J. H. WOLFE, *Secretary*.

## MICHIGAN AGRICULTURAL COLLEGE SECTION.

The first fall meeting of the Section was held on October 20, when J. G. Dean spoke on "The Recovery of Potash from Cement Kiln Gases." C. S. ROBINSON, *Secretary*.

At the regular meeting of the Section, held on November 22, D. L. Randall, of Albion College, spoke on "Chemistry in 1796." The following officers were elected for 1922: R. C. Huston, chairman; C. L. Bliss, vice chairman; Edward Eldridge, secretary; O. B. Winter, treasurer; and A. J. Patten, councilor. EDWARD ELDRIDGE, *Secretary*.

## MILWAUKEE SECTION.

At a special meeting of the Section, held on October 28, Frank C. Whitmore, of Northwestern University, addressed the members on "Organic Compounds of Mercury." The following officers were elected at this meeting to serve during 1922: Ralph M. Kibbe, chairman; Edwin J. Kern, vice chairman; O. A. Cherry, secretary; A. A. Chambers, treasurer; Henry C. Frey and C. A. Nash, councilors.

J. H. Walton, of the University of Wisconsin, addressed the meeting of the Section, held on November 18, his subject being "Some Factors Influencing the Rate of Crystal Growth." O. A. CHERRY, *Secretary*.

## MINNESOTA SECTION.

The following officers for the current year were elected at the meeting held on October 27: F. H. MacDougall, chairman; C. A. Mann, vice chairman; L. M. Henderson, Secretary; C. J. V. Pettibone, treasurer; R. A. Gortner and C. A. Mann, councilors.

At the regular monthly meeting, held on November 23, W. H. Hunter addressed the members on "Recent Researches in Organic Chemistry."

L. M. HENDERSON, *Secretary*.

## NASHVILLE SECTION.

The first meeting of the season, held on October 28, was given over to social features and to a discussion of plans for the year just beginning.

On November 18, two demonstration addresses, as follows, were delivered before the members of the Section: "Electrometric Titration with Use of Voltmeter as Indicator and the Measurement of  $p_H$  number," by L. J. Bircher, of the Vanderbilt University; and "The Arsenates of Sodium; the System  $As_2O_5-Na_2O-H_2O$ ; a Rapid Method of Determination of Total Arsenic in Insecticides," by W. A. Rudisill, of Vanderbilt University.

H. A. WEBB, *Secretary*.

## NEBRASKA SECTION.

The 100th regular meeting of the Section was held on October 27 at the University of Nebraska. J. M. Mayhew, of Lincoln, Nebraska, addressed the members on "Some Clinical Aspects of Blood Chemistry." Attendance, 40%.

The 101st regular meeting of the Section, held on November 28, had as its speaker, Roger Adams, of the University of Illinois, taking as his subject, "Researches on Synthetic Drugs in the United States." Attendance, 50%.

S. B. ARENSON, *Secretary*.

## NEW HAVEN SECTION.

James Kendall, of Columbia University, addressed the members of the Section on November 15, taking as his subject, "A Modified Ionization Theory."

BLAIR SAXTON, *Secretary*.

## NEW YORK SECTION.

Under the general heading of "Chemistry and Disarmament," the following program was given before the members of the Section, on November 18: "Chemical Research and Business," by Harrison E. Howe, of the National Research Council; "Recent Navy Tests," by Major H. S. Kimberly, and "Chemistry and Disarmament," by Francis P. Garvan, president of the Chemical Foundation.

HERBERT G. SIDEBOTTOM, *Secretary*.

## NORTHEASTERN SECTION.

The 170th regular meeting of the Section occurred on November 11, when the following program was presented to the members: "Chemical Clocks," by George Shannon Forbes, of Harvard College; "The Story of Rubber—What it is and What it Does," by Ralph E. Condor, of the Boston Woven Hose and Rubber Company; and "The Rubber Industry," moving pictures.

L. F. HAMILTON, *Secretary*.

## OKLAHOMA SECTION.

The Third Annual Meeting of the Oklahoma Section was held at Stillwater, Oklahoma, on October 28 and 29. The following program was carried out:

October 28—

Address—"Chemistry as an Experimental Science," by H. P. Cady.  
Announcements and Appointment of Committees, by Edwin DeBarr.  
Informal Reception to Dr. Cady.

October 29—

Presidential Address—by Edwin DeBarr.  
"Oil Field Practice in Handling Crude Oil Emulsions," by Sidney Born.  
"The Status of Chemistry in Oklahoma Teachers' Colleges," by Cliff R. Otto.  
"The Construction of Refinery Towers," by Julius Hansen.  
"Some Further Studies in Certain Organic Reactions in Which a Gas is Evolved," by Charles L. Nickolls.  
"The Petroleum Industry a Chemical Industry," by Charles K. Francis.  
"The Cost and Operation of a Shale Oil Still," by R. C. Beckstrom.  
"Some Further Uses for Aluminum Soap," by Hilton Ira Jones.  
"The Physiological Effect of Gossypol," by Paul Menaul.  
"The Nitrogen Distribution of the Two-Tenth Sodium Hydroxide Soluble Protein of Cottonseed Meal, Soy Beans, and Coconut," by W. G. Friedemann.  
"Some Quantitative Estimations by Means of the Spectroscope," by Edwin DeBarr.  
"The Effect of Starvation on the Composition of the Fats of Peanut-Fed Rabbits," by C. T. Dowell.  
"The Biologic Value of the Proteins of Peanuts, Soy Beans, and Coconuts," by C. T. Dowell.  
"A Talk on Helium," by H. P. Cady.  
Business Meeting and Annual Election.

At the above meeting, the following officers for 1922 were elected: Guy Y. Williams, president; Charles K. Francis, vice president; Hilton Ira Jones, secretary; J. B. Parks, treasurer; Edwin DeBarr, and C. T. Dowell, councilors.

HILTON IRA JONES, *Secretary*.

## OMAHA SECTION.

The 11th meeting of the Section occurred on October 11, when P. J. Deschavsky spoke on "Some Chemical and Industrial Aspects of Silk."

At the 12th meeting, held on November 8, R. N. Perkins discussed the "Sanitary Control of the Krug Park Swimming Pool at Omaha."

E. M. PARTRIDGE, *Secretary*.

## OREGON SECTION.

The first meeting of the season was held on October 29, at Reed College. Three addresses, as follows, were given: "Paint and Varnish Oils," by Paul Johnson; "Animal Fats and Oils," by Edward T. Luther; and "Soap Oils, Soap and Crude Glycerine," by H. Feldman.

PAGE R. BOYLES, *Secretary*.

## PHILADELPHIA SECTION.

On November 17, E. R. Weidlein, director of the Mellon Institute of Industrial Research, gave an illustrated lecture before the Section on the subject, "The Conservation of Heat in Power and Heating Systems by Means of 85% Magnesia, and the Applications of Magnesium Carbonate in the Chemical Industries."

J. HOWARD GRAHAM, *Secretary*.

## PITTSBURGH SECTION.

The 173rd meeting of the Section was held on October 20, when Alfred R. Powell, of the U. S. Bureau of Mines, spoke on "Sulfur in Coal and Coke."

The 174th meeting of the Section occurred on November 17. H. C. Bierman, of the Westinghouse Electric & Manufacturing Co., addressed the members on "Patents and the Chemist."

GEBHARD STREGMAN, *Secretary*.

## PUGET SOUND SECTION.

The October meeting of the Section was held under the auspices of the Olympian Chemical Club, at Tacoma, Wash., on October 22. The following program was carried out: Inspection of Tacoma Smelter, Informal Dinner and Meeting, and an address by Henry K. Benson, of the University of Washington, on "Chemical Industry in the State of Washington."

Wm. L. Haley, chief chemist of the Fisher Flouring Mills, spoke before the Section on November 19. His subject was "Chemical Control in the Milling Industry."

R. W. ELLISON, *Secretary*.

## RHODE ISLAND SECTION.

On November 25, Edgar F. Smith, president of the American Chemical Society, addressed the members of the Section, his subject being "Early Organic Chemistry in America."

SAMUEL T. ARNOLD, *Secretary*.

## ROCHESTER SECTION.

"What We Know About the Science of Nutrition," was the subject discussed by Elmer V. McCollom, of Johns Hopkins University, before the Section on October 17.

William H. Nichols, chairman of the Allied Chemical and Dye Corporation, spoke before the members of the Section on November 2, his subject being "America's Way Out of the Doldrums."

The 127th meeting of the Section, held on November 7, had as its speaker, Ralph Mellon, director of Clinical and Research Laboratories, Hahnemann Hospital, whose subject was "The Hydrogen Ion in Bacterial Environment and Bacterial Variability."

ERLE M. BILLINGS, *Secretary*.

## SAINT LOUIS SECTION.

On November 7, H. L. Ward, of Washington University, presented a paper before the members of the Section, his subject being "Physical Tests for the Purity of Organic Compounds."

H. A. CARLTON, *Secretary*.

## SAVANNAH SECTION.

The first fall meeting of the Section was held on October 13. Reports on the New York meeting were made by P. McG. Shuey and H. S. Bailey. This was followed by a symposium on "Nitrogen Determination," lead by R. F. Monsalvatge. Attendance, 43%.

F. I. Gibson, of the Southern Cotton Oil Co., spoke before the members of the Section, on November 10, his subject being "By-products of the Cotton Oil Industry." At this meeting the following officers for 1922 were elected: Eli H. Armstrong, chairman; P. McG. Shuey, vice chairman; Herbert P. Strack, secretary-treasurer; and Herbert S. Bailey, councilor.

HERBERT P. STRACK, *Secretary*.

## SOUTHEAST TEXAS SECTION.

The 18th meeting of the Section, held on November 4, had as its speaker, A. J. Hartsook, of the Rice Institute, taking as his subject, "Paper Making."

P. S. TILSON, *Secretary*.

## SOUTHERN CALIFORNIA SECTION.

The regular monthly meeting of the Section occurred on October 27, at the Radium Institute, Los Angeles, Calif., when an address was delivered by Rex Duncan on the subject, "The Chemistry and Physics of Radium," with special reference to its therapeutic action.

H. L. PAYNE, *Secretary*.

## SOUTH JERSEY SECTION.

On October 14, the members of the Section visited the plant of Joseph Bancroft and Sons Company, bleachers, dyers and finishers at Wilmington, Del.

The 11th regular meeting of the Section, held on November 22, had as its speaker, Edgar F. Smith, president of the American Chemical Society, who spoke on "Early Organic Chemistry in America." At this meeting the following officers for 1922 were elected: C. E. Burke, chairman; A. D. Holmes, vice chairman; M. H. Mahr, secretary-treasurer; and H. D. Gibbs, councilor.

H. W. MAHR, *Secretary*.

## SYRACUSE SECTION.

The 151st meeting of the Section was held on October 7. The first business to be transacted, after the dinner, was the election of the following officers for 1922: L. E. Wise, president; C. R. McCroskey, vice-president; W. B. Hicks, secretary; Louis Jordy, treasurer; A. C. Houghton and R. S. Fleming, councilors. Short speeches were made by several members of the section.

W. B. HICKS, *Secretary*.

## TOLEDO SECTION.

On November 11, the members of the Section heard an address by Frank G. Breyer, of the New Jersey Zinc Co., on the subject, "What Does my Program Mean to Me?"

T. E. MOORE, *Secretary*.

## UNIVERSITY OF ILLINOIS SECTION.

The 118th regular meeting of the Section was held on November 22. H. B. Lewis spoke on "The Importance of Sulfur in the Animal Organism." The following officers for 1922 were elected at this meeting: H. B. Lewis, chairman; J. H. Rudy, vice chairman; D. T. Englis, secretary; C. S. Marvel, treasurer; and Roger Adams and E. W. Washburn, councilors.

D. T. ENGLIS, *Secretary*.

## UNIVERSITY OF MICHIGAN SECTION.

Ernst Cohen, director of the Van't Hoff Laboratory, University of Utrecht, Holland, delivered lectures on November 1 and 2 before the Section, taking as his subject, "The Metastability of Matter and Its Bearings on Chemistry and Physics."

C. C. MELLORE, *Secretary*.

## VERMONT SECTION

On November 4, George Shannon Forbes, of Harvard University, spoke before the members of the Section, his subject being, "Modern Theories of Photochemical Reactions."

E. C. JACOBS, *Secretary*.

## VIRGINIA SECTION.

The 45th meeting of the Section was held on November 18. The address of the evening was by Graham Edgar on "Radiation as a Factor in Chemical Reactions."

ROBERT F. McCRACKAN, *Secretary*.

## WASHINGTON, D. C. SECTION.

The 322nd meeting of the Section occurred on October 25 at the Cosmos Club, when the following program was presented:

Presentation of the American Chemical Society's Portrait of Joseph Priestley, Discoverer of Oxygen, to the National Museum.

Acceptance of the Portrait by Charles D. Walcott, Secretary of The Smithsonian Institution.

"Development of Chemistry in the United States," by Edgar F. Smith, President of the American Chemical Society.

"Organization of the American Chemical Society at the Home of Priestley," by F. W. Clarke.

The 323rd meeting of the Section was held on November 10. Brief talks were made by Charles E. Munroe, W. D. Bigelow, R. B. Sosman, and other past presidents of the Section.

J. B. REED, *Secretary*.

## WISCONSIN SECTION.

The following program was presented before the members of the Section at the regular monthly meeting held on November 16: "The Decomposition of Nitrogen Pentoxide in Solution," by Roger H. Lueck; and "Hydrogen Persulfide," by J. H. Walton.

V. L. BOHNSON, *Secretary*.
